Under the municipal park commissioners there are 33 public parks with a total area of 644.38 acres, and the city supports' summer playgrounds; the state board of metropolitan park commissioners controls a large park system in the metropolitan park district, and a system of boulevards, connecting the several parks and other public reservations; there are nine metropolitan reservations, containing 677 acres, the largest being Lincoln Woods, of 460 acres, 4 m. north of the State House. Other metropolitan reservations are: Woonasquatucket Reservation (53 acres; 4½ m. west of the State House); Edgewood Beach (25 m. south of the State House); and the Ten Mile River Reservation (100 acres; 4½ m. north-east of the State House) on both sides of Ten Mile River. The finest municipal reservation is Roger
Williams Park (432 acres, of which 140 are water), with 9 m. of drives and boulevards, in the southern part of the city, 29 m. from the State House. It was a part of the original tract ceded to Roger Williams by Miantonomoh; 107 acres were a farm which Betsy Williams (d. 1871), a lineal descendant of Roger Williams, left to the city by will. In the park are a chain of lakes with a shore front of 7/2 m., a boat-house, a casino, a speedway and athletic grounds, a municipal natural history museum, and the Betsy Williams Cottage (1775). Other municipal parks are: Neutaconkanut (40 acres; 23 m. west of the State House) on high land commanding a view to the east and south; Davis Park (38 acres) with amusement grounds; Blackstone Park (43 acres, 13 m. east of the State House) along the Seekonk river; Hopkins Park (1 m. north of the State House), comprising the estate of Esek Hopkins (1710-1802), commander of the American Navy in the War of Independence, with a historical museum in the Admiral Hopkins House; and City Hall Park. Blackstone Boulevard is 1/2 m. long; and Pleasant Valley Parkway is 1 1/3 m. long. Enclosed by a railing near the eastern end of Power Street, on the bank of the Seekonk, is What Cheer State Rock, according to tradition the first landing place of Roger Williams.

In the North Burial Ground are the remains of Stephen Hopkins (1707-1758), a citizen of Providence, a delegate to the Albany convention of 1754, a colonial governor of Rhode Island (1755-1757, 1758-1762, 1763-1765, and 1767-1768), a member of the Continental Congress in 1774-1780 and a signer of the Declaration of Independence; of William Barton (1728-1831), who in the War of Independence captured General Richard Prescott near Newport on the 10th of July 1777; of Francis Wayland; and of Nicholas Brown, who was a patron of Brown University and one of the founders of the Providence Athenaeum and of the Butler Hospital for the Insane.

On the slopes of College Hill (or Prospect Hill) in the east side near the business district, is Brown University (1764)—one of the eight colleges in the United States founded before 1796—closely connected with the history of Providence, Rhode Island, and the Baptist Church in America. It has an undergraduate department for men, with courses, largely elective, leading to the degrees of A.B. and Ph.B., and courses, almost wholly prescribed, in civil, mechanical and electrical engineering. It includes, besides "The Women's College in Brown University," a separate college for women, and a graduate department open to both men and women. The campus is shaded by some fine elms and is surrounded by an iron fence with beautiful memorial gates. In 1916 there were twenty-two buildings, including the following: University Hall (erected in 1776 and used during the War of Independence by American and French soldiers; Sayles Memorial Hall (1881), containing the chapel, lecture halls and seminary rooms; three library buildings, the John Hay Library (which occupies the site of the old President's House), the old University Library (1878) and the John Carter Brown Library (1904); the Ladd Astronomical Observatory, with a 12-in. equatorial and much other valuable equipment; Rhode Island Hall (1840), containing a biological laboratory and a natural history museum; Manning Hall (1834), containing an art museum; Wilson Hall (1891), containing a physical and a psychological laboratory; Rogers Hall (1862), a chemical laboratory; an engineering building (1903); the Lyman gymnasium (1891) and Colgate Hoyt swimming pool (1904); an administration building (1902); the Sayles gymnasium (1896) for women; Rockefeller Hall (1903), occupied by the Brown Union, a students' organization and the Young Men's Christian Association; the residence halls: University Hall (1776, remodelled 1883), Hope College (1822 and 1891), Slater Hall (1879), Maxey Hall (1895), and Caswell Hall (1903); and the Carrie (clock) Tower, erected in 1904 by Paul Bajnotti, of Turin, Italy, as a memorial to his wife, Carrie Mathilde Brown, of Providence. Besides the general library, containing (1909) about 164,000 volumes, the university owns the separately housed John Carter Brown Library of 20,000 volumes, one of the best collections in the world of material on early American history (especially of books printed before 1800), which, with an endowment of $500,000, was presented to the university in 1901 in accordance with the will of John Nicholas Brown, the son of John Carter Brown (1797-1874) a prominent Providence merchant, who began the collection. In 1909 the university had an endowment fund of $3,416,744, 90 instructors and 993 students, of whom 88 were graduates; of the undergraduates 179 were enrolled in the Women's College. The charter of the institution requires that it shall be governed by a board of thirty-six trustees, of whom twenty-two shall be Baptists, five Friends, four Congregationalists, and five Episcopalians, and by twelve fellows (including the president) of whom eight (including the president) shall be Baptists, and the rest indifferently of any or all denominations. At the time it was framed the charter was considered extraordinarily liberal. One of the provisions is included regarding the character of instruction to be offered: first that "the public teaching shall in general respect the sciences," and second, that "into this liberal and catholic institution shall never be admitted any religious tests, but on the contrary all the members hereof shall forever enjoy full, free, absolute and uninterrupted liberty of conscience." The government has always been largely non-sectarian in spirit, and a movement was on foot in 1910 to abolish the denominational requirements for trustees and fellows.

Brown University, the first institution for higher education established by American Baptists, was incorporated in 1764, and although still under its original charter was known for the first ten years as Rhode Island College. The Latin or preparatory school was opened at Warren in 1764 and the college was started there in 1766, but in 1770 the institution was removed to Providence. Through its work was interrupted by the War of Independence, the institution was reopened in 1782 and ten years later it began to receive aid from Nicholas Brown (1769-1841), a wealthy merchant who graduated from the Rhode Island College in 1786. He was graduated in 1814 by William Herbert Perry Faunce (b. 1859), who graduated at Brown in 1880. In 1900 and 1901 more than $2,000,000 was added to the endowment of the university. The Women's College was founded in 1801, and in 1852 it was accepted by the corporation as a department of the university. Among distinguished alumni of Brown are Henry Wheaton (1785-1838), John Hay, Richard Olney, James Burrill Angell (b. 1829) Adoniram Judson, William Learoyd Adams, Amasa Walker, Edward Waldo Sayles, Benjamin Way, William Edwards Evans, G. A. Roper, Charles J. Banks, John Warren, Daniel C. Huntington, Elisha Root, Charles G. Van Doren, and Edward C. Pickering.

In Providence are the Rhode Island Normal School (in the north part of the city, in Gaspee St.; established in 1854; discontinued in 1857; re-established in 1871), which has a fine building (1858), the Rhode Island Institute for the Deaf (1876), and the Rhode Island School of Design (1877; partially supported by the state, since 1882, and by the city), affiliated with Brown University. The following secondary schools are in the city: four high schools, one of which is technical, La Salle Academy (1871; Roman Catholic, under the Brothers of the Christian Schools), Saint Xavier's Academy (Roman Catholic), the College of the Holy Cross, the Roman Catholic, and Moses Brown School (Friends; at Portsmouth in 1784-1788; re-established in Providence in 1814), the Brown school for boys (non-sectarian), Fielden-Chace school for girls (non-sectarian), and the Lincoln School (non-sectarian). The public school system has benefited by the presence of Brown University, whose faculty has been largely represented on the school committee; by an agreement with the university its professor of the theory and practice of education is director of the training department in the high schools, and there are other schemes of co-operation. Transition classes between the kindergarten and primary were

1 So called because Roger Williams was greeted here by Indians, who said "What cheer, Netop?" ('Netop' meaning friend).
long peculiar to the Providence public schools. In 1908 a "Sunshine School" was established, with sun and fresh-air treatment for invalid pupils.

The Providence Journal (Independent, daily, 1824), the most important newspaper published in the state, and the Evening Bulletin (Independent, 1863) are controlled by the same company.

The charitable institutions include the Rhode Island Hospital (1863, private), the Prisoners’ Aid Association (1872), the Providence Rescue Home and Home, Nissim (1865), the Bethany Home or State Hospital (1892), a temporary home for women; the House of the Good Shepherd (1904), the Lying-In Hospital (1884), Saint Joseph’s Hospital (1862; Sisters of St Francis), two dispensaries, a City Hospital, and the Treatment of Contagious Diseases (1809) on Capitol Hill; the Butler Hospital for the Insane, which is one of the oldest institutions of its kind in the country, was established by a bequest of $91,980,963, $12,517. 512

$91,980,963, $12,517.

All these were mercantile (by far the greatest storehouse of value) and in the state’s capital. The Richardson (by far the greatest storehouse of value) is the Rhode Island Company’s (referred to as the Richardson Co.), which was in existence for over 100 years. The Richardson Co. was in existence for over 100 years.

According to a 1905 history of the Richardson Co., the company was founded in 1647 by three freeholders, and it was the oldest company in the state. The company was dissolved in 1909.

Two of the Richardson Co.’s 1805 acts as a board of aldermen, one from each of the ten wards, who may redistrict the city every five years, and until 1895 acted as a returning board, and which is presided over by the mayor; and a common council of four members from each ward, elected in open ward-meeting by the qualified freeholders of the ward.

As a result, the Mayor and aldermen and common council meet together to organize and to plan municipal works otherwise provided for. The greater size of the common council gives it the power in joint sessions; and although the vote of the city for mayor is normally Democratic, the vote of the qualified freeholders (which is only about 40% of the total vote) for common-councilmen and aldermen is always Republican.

The two houses, acting before 1895 as a board of registration; the council now chooses a board of three members with a term of three years. The city council and a school committee of 33 members (3 ex officio; 30 elected by wards, one each year from each ward for a three-year term) control the public schools.

The mayor has the veto power only since 1854; and until 1866 his veto could be overridden by a majority vote; a three-fifths vote of each chamber is now necessary. The mayor was at the head of the police department until 1901, when a commission of three was created; until 1906 these police commissioners were appointed by the governor of the state, but they are now elected by the mayor with the approval of the board of aldermen. In the same way the mayor appoints a commissioner of public works for a term of three years. The three commissioners of the fire department and the three members of the board for the assessment of taxes are chosen by the city council.

The city treasurer (since 1858) and the overseer of the poor and the harbour-master (since 1866) are elected by popular vote. The municipality owns and operates the waterworks and there are municipal bath-houses.

Providence was founded in 1636 by Roger Williams, an exile from Massachusetts, and its early history is closely bound up with the early history of Rhode Island, it being one of the four towns out of which this commonwealth was formed. Having agreed with Canonicus and Miantonomo, the Narraganset sachems, for the purchase of a considerable tract of land, Williams built his house about 50 ft. east of what is now North Main Street and nearly opposite the confluence of the Moshassuck and Woonasquatucket rivers, and he named the place Providence in recognition of his divine guidance hitherto. He and a few companions who had accompanied him into exile immediately established a town government with monthly town meetings, and in the next year, 1637, after the arrival of a few more settlers, a plantation covenant was adopted which laid the basis of the future commonwealth on a new principle—the complete separation of religious and civil affairs. In 1644 Williams secured a charter uniting Providence, Aquidneck (Portsmouth), and Newport, as “The Incorporation of Providence Plantations in the Narraganset Bay in New England” ; these two towns (and Warwick) organized in Providence in May 1647 under this government. The charter of the 24th of November 1663, to the Governor and Company of the English Colony of Rhode Island and Providence Plantations, perpetuated the name Providence Plantations, which still remains a part of the legal title of the state. Providence was incorporated as a town by
the Colonial Assembly in 1649; in 1730-1732, when the area of Providence was 370 sq. m., Scituate (including Foster), Gloucester (including Burrillville), and Smithfield (including North Smithfield and Lincoln) were set off; in the next thirty years the area of the township was reduced to 34 sq. m. by the separation of Cranston, Johnston and North Providence, parts of which have been re-annexed since 1860. Providence was chartered as a city in 1832. During King Philip's War. in 1676, the town was attacked by Indians and the northern half was burned. In June 1772, a British schooner, the "Gaspee," while chasing a Providence packet-boat ran aground on what has since become known as Gaspee Point, whereupon its capture was planned by John Brown (1736-1828), a Providence merchant, and the plan— including the burning of the vessel—was carried out under the command of Abraham Whipple (1733-1819). During the war much privatisation was carried on from Providence. The British occupation of Newport during the War of Independence caused the transfer of the important foreign commerce of that city to Providence, but as a consequence of their superior railway facilities most of this went to New York and Boston before the middle of the 19th century. In September 1815 Providence was visited by a gale which did about $1,000,000 damage to its shipping and other property. In 1830 Providence had ceased to be a great port and had begun to be a textile manufacturing place. Until 1900 Providence was one of the two capitals of the state, Newport being the other; since 1900 it has been the sole capital.

PROVINCE (Lat. provincia; perhaps a contraction of provinces), a term originally applied, in ancient Rome, to the department or sphere of duty assigned to one of the higher magistrates, the consuls and praetors.1 When, with the spread of the Roman arms, the government of conquered countries grew to be one of the most important duties of the higher magistrates, the term province, from designating the government of a conquered country as one particular duty of a Roman magistrate, came to be used generally as a designation of the country itself. Thus in later days it was applied to analogous territorial subdivisions of a country, as opposed to the centre of government; and apart from any territorial signification, the term is used generally for a sphere of duty.

It is to the older sense of the term as a subject territory lying outside of Italy and governed by Roman magistrates that the following historical remarks apply:—

As distinguished from Italy, the provinces paid tribute to Rome, for at least from the time of the Gracchi, it was a recognised constitutional principle that the provinces were the estates of the Roman people and were to be managed for its benefit. Under the republic the constitution of a province was drawn up by the victorious Roman general assisted by ten commissioners appointed by the senate from its own body, and the province was henceforth governed on the lines laid down in this constitution or charter (lex provinciae). For administrative purposes the province was divided into districts, each with its capital, the magistrates and council of which were responsible for the collection of the district taxes. For judicial purposes the province was divided into circuits (conventus), and in the chief town of each circuit the governor of the province regularly held assizes.

1 Only those magistrates who had imperium (military power) had a province. When the province of a quaestor is mentioned it refers to the province of the consul or praetor to whom the quaestor is subordinate. In familiar language any business was called a province.

PROVINCE

Cities taken by the sword were destroyed, and their lands were turned into Roman domains and were let out by the censors at Rome to private persons, who undertook to pay a certain proportion of the produce. Royal domains, such as those of Syracuse, Macedonia, Pergamum, Bithynia and Cyrene were also confiscated. On the other hand communities which surrendered without offering an obstinate resistance were usually allowed to retain their personal freedom and private property, and their chief town was left in the enjoyment of its territory and civil rights; but all the lands were subjected to a tax, consisting either of a payment in kind (vectorial) or of a fixed sum of money (tributum, stipendium), and in some cases a custom-duty (portuorium) was levied. It is to this latter class of communities (the cives vicinae) that the large majority of the provincial states belonged. In a better position were those states whose freedom was guaranteed by Rome on the ground of old alliances or special loyalty. Their freedom was recognized either by a treaty or by a decree of the Roman people or senate. As a decree of the people or senate could at any time be recalled, the position of the free states without a treaty was more precarious than that of the treaty states (cives foederatae). The latter, though not allowed to meddle in foreign politics, enjoyed a certain amount of internal freedom, retained their lands, paid no taxes, and were bound to render those services only which were expressly stipulated for in the original treaty, such as furnishing ships and troops, supplying corn at a certain price and receiving Roman officials and soldiers en route. Amongst these treaty states were Massilia (Marseilles), Athens, Rhodes and Tyre. The privileges of the free but not treaty states were somewhat similar, but, as stated, more precarious. All political distinctions, save that between slave and freeman, disappeared when Caracalla bestowed the Roman franchise on the whole empire.

Provincial Diets.—Apart from the government by Roman officials, every province appears to have had, at least under the empire, a provincial assembly or Diet of its own (concilium or commune), and these Diets are interesting as the first attempts at representative assemblies. The Diet met annually, and was composed of deputies (legati), from the provincial districts. It arranged for the celebration of religious rites and games, especially (under the empire) for the worship of the emperor, the neglect of which was severely punished. The actual celebration was under the conduct of the high priest of the province, a person of much dignity and importance, perhaps the forerunner of the Christian bishop. The Diet also decreed the erection of statues and monuments; it passed votes of thanks to the outgoing governor, or forwarded complaints against him to Rome; and it had the right of sending embassies direct to the senate or the emperor.

The Provincial Governor.—The provinces were administered by governors, who were either of Roman citizens or of Roman free born, but who held their office for one year. From the formation of the first provinces in 227 B.C. down to the time of Sulla (82 B.C.) the governors were praetors (see Praetor); from the time of Sulla to that of Augustus the praetors remained in Rome, and Sulla had established the office of governor of a province with the title of praetor. This applies, however, only to provinces which were in a settled state and could consequently be administered without a large military force. A province which was on the frontier of the empire, was committed to the care either of one of the consuls for the year or of a commander specially appointed for the purpose with the title of proconsul, who might be one of the consuls of the preceding or of a previous year, or else a former praetor, or even, in rare cases, a private individual who had held neither consulate nor praetorship. Thus the distinction between consular (or proconsular) and praetorial (or propraetorial) provinces varied from year to year. In the latter or provincial provinces the praetors, on the other hand, were always the praetors of the Roman empire. At the close of the republic, however, we find even such a peaceful province as Asia administered by a proconsul. In the earlier period of the republic the senate either before or after the election determined which provinces were to be assigned to consuls and which to praetors, and after their election the consuls arranged between themselves by lot or otherwise which of the provinces nominated by the senate each should have, and similarly with the praetors. But in order to guard against partiality the Sempronian law of 123 B.C. provided that the senate should yearly nominate the two consular provinces before the election of the
PROVINCETOWN

consuls, and that the consuls should after their election but before their entry on office arrange between themselves which of the two provinces each should have. The Pompeian law of 53 B.C. enacted that no one should hold the governorship of a province till at least five years had elapsed after his election or should hold the office of praetor for a second term. But after the time of Augustus, the Roman magistracy, into an independent office. Like magistrates at Rome a provincial governorship was regularly held for one year; but, unlike them, it could be prolonged, formerly by a vote of the people, and later by a vote of the senate. In the time of Caesar (46 B.C.) enacted that the governorship of a consular province should be held for two years, that of a praetorian province for one year. The necessary supplies of men and money were voted to the governor by the people of the Roman province. He had the grand jury, or law committee (legalis), a quaeator (q.e.), and numerous subordinates. The lieutenants were nominated by the senate from men of senatorial rank; if they proved incompetent, the governor dismissed them; if successful, they generally were promoted to the governorship of another province. Besides these the governor took with him from Rome a number of young men of the upper classes to assist him in the government. These were known as the companions (comites) or suite of the governor. He also had prætorian guards (see Praetorian Guards). These members of his suite were employed by the governor himself, who was responsible for them, but they were maintained at the expense of the state, and under the empire regular pay. In addition to the magistrates, the governor had army officers of the legions, the horde, the legates, the dragonaries, &c., to be selected from freedmen and slaves for the personal service of the governor. Under the republic the governor was not allowed to take his wife with him to his province; under the empire he might do so, but he was answerable for her conduct. Before he entered on his province, the governor, clad in the purple military robe of his office, offered sacrifice on the Capitol; then immediately after receiving the imperium or military command he marched out of the city (for the imperium could only be exercised outside of Rome and the province was under the direction of the city), preceded by his sergeants (lictores), and accompanied by his suite. He was bound to travel direct to his province; the means of transport were supplied partly by the state, partly by voluntary subscription. The journeys were hazardous, and the office began from the day he set foot in his province, but the time of arrival varied with the length and difficulty of the route. In the hands of the governor all powers military and civil were united. He governed as he pleased, and the troops in the provinces were liable to raise levies of Roman citizens as well as of provincials, and to make requisitions of war material. He possessed both criminal and civil jurisdiction; as criminal judge he had the power of life and death, and from his sentence none, but Roman citizens could appeal; as civil judge he was guided partly by the charter of the province (lex provinciae), partly by the edict which it was customary for him to issue before his entrance on office (compare Praetor), partly by the charter of any new provinces which might be created; his decisions were ruled by the charter or by the governor's own edict. Under the empire, a governor of a province wrote a commentary on the provincial edict, and it is usually supposed that this was a general edict drawn up for use in all the provinces, and that the provincial charters were abrogated by an edict of the emperor. The lengthened periods during which the governors, at least in the imperial provinces, held office, together with the oversight exercised by the emperor, alleviated materially the position of the provincials under the empire. In order to keep himself well informed of what was passing in the empire, Augustus established a post whereby official despatches were forwarded by couriers and official persons were conveyed by coaches. The post, however, was only for the use of those who were the equals of the emperor, and there was an exception, to avail himself of it. (J. G. Fr.: X)

Authorities.—The most exhaustive account of the Roman provinces and their administration will be found in Marquardt, G., De Gouvernement des Provinces des Anciens Romains (2 vols., 1818-1819); Caistor, The Roman Provincial Administration (1879); Mommsen, Roman Provinces under the Empire (1884); C. Halg, L'Administration des provinces senatoriales sous l'Empire, with full bibliography of the subject; and T. M. Taylor, Constitutional and Political History of Rome (1899).

PROVINCETOWN, a township at the N. end of Cape Cod, in Barnstable county, Massachusetts, U.S.A., Pop. (1890), 4642; (1900), 4347; (1910 U.S. census) 4369. Area about 93 sq. m. The township is served by the New York, Providence & Boston, and the New York, New Haven & Hartford railroads.

The harbour, which is important as a harbour of refuge, is protected on the east by land, and the Federal government has strengthened this protection by dikes and groins and other sand-catch ing devices; it has five lighthouses. There is a magnificent beach stretching 30 m. from Provincetown village to Eastham. The village is a summer resort. Through many generations the inhabitants have gained their living chiefly from the sea; the township's fisheries, however, have greatly decreased in importance (the invested capital diminishing 67.1% in 1885-1895). The prosperity it retains is not a little due to Portuguese from the Cape Verde Islands and the Azores, and to British Americans. Provincetown village was long second only to Gloucester in the cod fisheries, which low prices and the introduction of larger vessels and correspondingly costier fittings have greatly

1 Sullica excluded the equites from the list; the lex Aurelia (70) reinstated them.
handicapped. Whaling retains a remnant of its old importance, and there are also mackerel and shore fisheries, oil-mills, and storage establishments for preserving fish for solid and balance and canning works for berries. The first settlement here was made about 1680; it became a "district" or precinct of Truro in 1714, and was established as a township with its present name in 1727. Provincetown harbour was possibly visited by Gaspar Cortereal in 1501; Gosnold explored it and its vicinity in 1602, and John Smith was here in 1614. It was in this harbour that the "Mayflower" compact (see MASSACHUSETTS) was drawn up and signed by the Pilgrims before they proceeded to Plymouth, in 1620; here John Carver was chosen the first governor of Plymouth Colony, and Provincetown was the first landing place (on Saturday the 11th [of] November) of the Pilgrims in the New World. A memorial of the "compact," of polished Acton granite, 6 ft. high, with two bronze tablets, was erected before the town-hall by the Old Colony Commission, and on High Pole Hill on the 20th of August 1907 the cornerstone of a second memorial (completed in 1909, dedicated Aug. 5, 1910), a granite tower, 252 ft. high, was laid, addresses being delivered by President Roosevelt, James Bryce and H. C. Lodge. In Provincetown harbour, on the 1st of January 1862, James M. Moulton and John Slidel, the "envoys of the first consul to the Great British empire," were shipwrecked, and, while fishing, were landed by a Federal vessel from the British ship "Trent," were restored by the Federal authorities to H.B.M.S. "Rinaldo," after their detention in Fort Warren in Boston harbour.

PROVINS, a town of northern France, capital of an arrondissement of the department of Seine-et-Marne, at the junction of the Durtain with the Vouzie (an affluent of the Seine), 59 m. E.S.E. of Paris by rail. Pop. (1900), 7546. The town enjoys a certain reputation for its mineral waters (which contain iron, lime, and carbonic acid, and are used for bathing and drinking), and is also known from its trade in roses, but it derives a higher interest from numerous remains of its medieval prosperity. Provins is divided into two quarters—the ville-haute and the less ancient ville-basse—which in the 13th century were surrounded by fortifications. There still remains a great part of these fortifications, which made a circuit of about 4 m., strengthened at intervals by towers, generally round, and now, being bordered with fine trees, form the principal promenade of the town. The large tower situated within the ville-haute, which was known as the Mont Ste. Catherine, or the "provinciers' tower," is one of the most curious of the 12th century and now extant. The base is surrounded by a thick mound of masonry added by the English in the 15th century when they were masters of the town. The tower serves as belfry to the church of St Quiriaire, which dates its foundation from the 12th century. These two buildings in the ville-haute rise picturesquely from the crest of a steep wooded hill above the ville-basse. The church preserves among its treasures the pontifical ornaments of St Edmund of Canterbury (d. 1242). The interior is plain, but very beautifully proportioned. The appearance of the exterior suffers from an inappropriate dome erected above the crossing. The palace of the counts of Champagne, some fragments of which also belong to the 12th century, is occupied by the communal college. The old tithe-barn is a building of the 13th century with two fine vaulted chambers, one of which is below ground. The church of St Ayoul dates from the 12th to the 14th centuries, the transept being the oldest part; it is in a state of great dilapidation, and the choir is used as a stockhouse. St Croix belongs partially to the 12th century. The remains in the middle ages, extend beneath portions of the town. On Mont Ste Catherine, opposite Provins, the general hospital occupies the site of an old convent of St Clare, of which there remains a cloister of the 14th century. The sub-prefecture, tribunals of first instance and of commerce are among the public institutions. There is an active trade in grain, livestock and wool, and the industries include flour-milling, nursery-gardening, brickmaking, and the manufacture of porcelain, pianos, gas and petrol engines, agricultural implements and sugar.

Provins began to figure in history in the 9th century. Passing from the counts of Vermandois to the counts of Champagne, it rapidly attained a high degree of prosperity. Cloth and leather were its staple manufactures, and its fairs, attended by traders from all parts of Europe, were of as much account as those of Beaucaire, while its money had currency throughout Europe. In the 13th century the population of the town is said to have reached 60,000; but the plague of 1348 and the famine of 1349 proved disastrous. The Hundred Years' War, during which Provins was captured and recaptured, completed the ruin of the town. During the religious wars it sided with the Catholic party and the League, and Henry IV. obtained possession of it in 1592 only after thirteen days' siege.

PROVISION (Lat. provision), a term meaning strictly the act of providing, or anything provided, especially in respect of food (provisions) or other necessaries. In constitutional law it signifies the act by which an ecclesiastical office or benefice is conferred by a person having competent authority for the purpose; and the word is specially used of appointments made by the pope in derogation of the rights of ecclesiastical patrons. Papaly or, as it is sometimes called, an "act of provision," was the act whereby the pope or any other person holding an ecclesiastical benefice, directed prelates to collate his nominees to canonicies and other benefices, but it was during the pontificate of Innocent IV. (1243-1254) that the practice first assumed alarming proportions. Vigorous protests were then made in England and France against the large number of papal provisions in favour of non-resident Italian clerks. These protests were not without effect for a while; but the popes, finding it impossible to carry on the work of government without this means of rewarding their servants, soon began to show little regard to national protests. The English parliament held at Carlisle in 1307 petitioned the king for a remedy against this abuse, but thoug promised redress nothing was done. Meanwhile the popes had been asserting claims to appoint bishops in certain events on their own initiative, and at last Clement V. (1305-1313) reserved to himself the right of appointment in all cases. After his time there is scarcely an instance of an English bishop being elected in accordance with the older procedure by the cathedral chapter. If an election were made the pope usually either overrode it by papal bull, or appointed a temporal governor to be followed by an elected clerk by a bull of provision. The Hundred Years' War caused an outbreak of indignation against the use of papal provisions, whether to the canonicies and collative offices or to bishoprics. The popes had taken up their residence at Avignon and had become mere creatures of the kings of France. The English nobility and gentry were bitter at seeing vast sums of money pass out of the country into the hands of their enemies. To remedy the evil the first Statute of Provisors was enacted in 1351. It declared that the free elections of bishops and other dignitaries should take place in accordance with the ancient practice; that bishops and ecclesiastics should have free presentations to benefices and offices in their gift; that in the event of any provision being made by the pope the king should have the same right of collation as his predecessors had before they granted free election; and similarly where the pope provided to a benefice or office in the gift of secular or regular clergy the king was to have the collation for that occasion. Provisors who interfered with the rights of the king or patron were liable to arrest and imprisonment on conviction. The act was supplemented in 1367 and 1369, and it was also enacted that no secular and no person outside the realm were prohibited and persons who offended were made liable to outlawry. This legislation against papal provisions was anti-clerical rather than anti-papal. There are no signs that it was promoted by the English clergy, who seem to have accepted the claim of the popes to control their patronage. In spite of the statutes the popes still continued, as the papal registers show, to make provisions to English benefices and offices, and it is evident that the statutes were not enforced. The Statute of Provisors was confirmed by a second statute in 1364, but this again seems to have had little effect. Attempts were made to
establish a concordat on the subject between the king and pope: its terms, however, were all in favour of the latter. At last, in 1380, a third Statute of Provisors was enacted which provided that the statute of 1353 should be firmly holden for ever and "put in due execution from time to time in all manner of points." The new statute was carried into effect as regards canonsries and benefices; but, until the Reformation, bishops were nominally appointed by a papal bull of provision. The person appointed, however, was usually nominated by the king, and the bull was not issued without his consent.

**AUTHORITIES.**—Statutes of the Realm; Calendar of Papal Registers: J. Le Neve, Fasti ecclesiae anglicanae; Rolls of Parliament; F. W. Maitland, Canon Law in the Church of England; W. Stubbins, Constitutional History of England; Anglia sacra. (G. J. T.)

**PROVISIONAL ORDER,** a method of procedure followed by several government departments in England, authorizing action on the part of local authorities under various acts of parliament. Procedure by provisional order is a substitute for the more expensive course of private bill legislation; it is usually employed for such purposes as alteration of areas, compulsory purchase of land, building of light railways, &c. A preliminary local inquiry is first held in public by an inspector of the department to whom application has been made to issue it. Upon the report of the inspector and other information the department decides whether or not to issue the order. The order when issued has no force until it is confirmed by parliament. For this purpose it is included with other orders in a confirming bill, introduced by the minister at the head of the department concerned. In both houses of parliament all provisional order bills are referred to examiners for compliance with standing orders. In the House of Lords, if a provisional order bill is opposed, it is referred to a select committee and then to a committee of the whole house; if not opposed, it goes, after second reading, to a committee of the whole house, and in both cases then proceeds as a public bill. In the House of Commons, the bill goes after second reading to the committee of selection or to the general committee on railway and canal bills; if opposed it is treated as an unopposed private bill; if opposed it goes to a private bill committee, which hears evidence for and against.

**PROVO,** a city and the county-seat of Utah county, Utah, U.S.A., on the Provo river, 3 m. E. of Utah Lake, and about 45 m. S. by E. of Salt Lake City. Pop. (1890), 5150; (1900), 6185 (1176 foreign-born); (1910) 8925. Provo is served by the Rio Grande Western and the San Pedro, Los Angeles & Salt Lake railways. It is situated at an altitude of about 4350 ft., in a region of fine scenery, Provo Cañon, Bridal Veil Falls and Utah Lake being of especial interest. The city has a general hospital, the seat of the state mental hospital and of Brigham Young University (a Mormon institution), founded by Brigham Young in 1875, opened as an academy in 1876, and incorporated in 1896; it comprises a college and high commercial, music, arts and trades, agricultural and preparatory schools. Provo has various manufactures, including woolen goods, lime, pottery and bricks, and the city is a shipping point for a fertile agricultural and fruit-growing region. Within a radius of forty or fifty miles of Provo are a number of important mines. Provo was settled in 1849 and was chartered as a city in 1851.

**PROVOST** (through O. Fr. provost, mod. prévôt, Lat. praepositus, set over, from praeposere, to place in front), a title attached to various ecclesiastical and secular offices. In ecclesiastical usage the word *praepositus* was at first applied by the Church fathers to any ecclesiastical ruler or dignitary. It early, however, acquired a more specific sense as the official next in dignity to the abbot of a monastery, or to the superior of a single cell. Thus in the rule of St Benedict the *praepositus* is the superior of the monastery immediately subordinate to the abbot, the dean (*decanus*) being associated with him. From the Benedictine rule this arrangement was taken over by Chrodegang of Metz when he introduced the monastic organization of cathedral chapters. In these the provostship (*praepositura*) was normally held by the archdeacon, while the office of dean fell to the archpriest. In many cathedrals the temporal duties of the archdeacons made it impossible for them to fulfil those of the provostship, and the headship of the chapter thus fell to the dean. In England the title *"provest"* has thus everywhere given way to that of "dean"; in Germany, on the other hand, "Probst" is still the style of the heads of certain chapters. The title has also been preserved in certain dioceses of the German Evangelical Church as the equivalent of *Superintendent*, and both the Roman Catholic and Protestant chaplains-general of the forces have sometimes, e.g. in Prussia, the title Feldprobst. The heads of Augustinian and Dominican friaries are termed "provest or prior" (*praepositus vel prior*), those of Cistercian monasteries "provest or warden" (*praepositus vel custos*). Finally the name *praepositus* was sometimes used for the secular advocatus of a monastery. With the ecclesiastical use of the title is connected its English application to the heads of certain colleges; "provest" is still the style of the principals of Queen's, Oriel and Worcester Colleges at Oxford, of King's College at Cambridge, of Trinity College at Dublin and of Eton College.

As a secular title *praepositus* is also very old; we need only instance the *praepositus sacri cubiculii* of the late Roman Empire, and the *praepositus palatii* of the Carolingian court. The important developments of the title in France are dealt with below. From France the title found its way into Scotland, where it survives in the style (provest) of the principal magistrates of the royal boroughs ("lord provest") in Edinburgh, Glasgow, Aberdeen, Perth and Dundee, and into England, where it is applied to certain officers charged with the maintenance of military discipline. A provost-marshall is an officer of the army appointed when troops are on service abroad for the prompt repression of all offences. He may at any time arrest and detain for trial persons subject to military law committing offences, and may also carry into execution any punishments to be inflicted in pursuance of a court martial (Army Act 1881, § 74).

A provost-sergeant is an officer responsible for the maintenance of order when soldiers are in the United Kingdom. A provost-sergeant may be either garrison or regimental, and he has under his superintendence the garrison or regimental police.

(W. A. P.)

**The Provost in France.**—The word *prévôt* (provest) in old French law had many applications. In conformity with its etymology (*praepositus*) it could be applied to any person placed at the head of a branch of the public service, a position which, according to the old principles, habitually carried with it a right of jurisdiction. It is thus that there was at Paris the "provest of Paris," who was a royal judge, and the "provest of the merchants" (*prévôt des marchands*), the head of the Paris municipality. There were besides—to mention only the principal provosts—the "provests of the marshals of France" (*prévôts des marchands de France*), of whom more below; the "provest of the royal palace" (*prévôt de l'hôtel du roi*) or "grand provost of France" (*grand prévôt de France*), and the "provest general" (*prévôt général*) or "grand provost of the mint" (*grand prévôt des monnaies*). But the most important and best known provosts, who formed part of a general and comprehensive organization, were the "royal provosts" (*prévôts royaux*), the lower category of the royal judicature. It must be borne in mind, however, that the magistrates belonging to the inferior category of royal judges (*juges subalternes*) had different designations in many parts of France. In Normandy and Burgundy they were called *châtelains*, and elsewhere—especially in the south—*vouliers*.

These were titles which had established themselves in the great provostships and were connected with their reunion with the Crown and had survived this. The royal provosts on the other hand, were a creation of the Capetian monarchy.

The date of this creation is uncertain, but was without doubt some time in the 11th century. The provosts replaced the viscounts wherever the viscounty had not become a fief, and

1 Where, however, the head-master, though technically subordinate to the provost, is the effective head of the school.

2 Thus in a register of the Châtelet of Paris in the 14th century, we read: "À Paris est la prévôté de Paris et celle des marchands."
it is possible that in creating them the Crown was imitating the ecclesiastical organization in which the provost figured, notably in the chapters. The royal provosts had at first a double character. In the first place they fulfilled all the functions which answered locally to the royal power. They collected all the revenues of the domain and all the taxes and dues payable to the king within the limits of their jurisdiction. Doubtless, too, they had certain military functions, being charged with the duty of calling out certain contingents for the royal service; there survived until the end of the ancien régime certain military provosts próvôts d'épée (provosts of the sword) who were replaced in the administration of justice by a lieutenant. Finally, the provosts administered justice, though certainly their competence in this matter was restricted. They had no jurisdiction over noblemen or over feudal tenants (hommes de foi), who claimed the jurisdiction of the court of their over-lord, where they were judged by their peers—the other vassals of the same lord. Neither had they jurisdiction over the open court lords. This authority, which was the propria pars, where this belonged to local seigneurs; and even in the towns over which they were set their jurisdiction was often limited by that of the municipal courts established for the benefit of the burgesses. The second characteristic of the old provosts was that their office was farmed for a limited time to the highest bidder. It was simply an application of the system of farming the taxes. The provost thus received the speculative right to collect the revenues of the royal domain in the district under his jurisdiction; this was his principal concern, and his judicial functions were merely accessory. By these short appointments the Crown guaranteed itself against another danger: the possible conversion by the functionaries of the function into a property. Very early, however, certain provostships were bestowed en garde, i.e. the provost had to account to the king for all he collected. The próvôts en ferme were naturally a source of abuses and oppression, the former seeking to make the most of the concession he had bought. Naturally, too, the people complained. From Joinville we learn how under St Louis the provostship of Paris became a próvôt en garde. At the death of Louis XI. the próvôts en ferme were still numerous and provoked a remonstrance from the States-general of 1484. Their suppression was promised by Charles VIII. in 1493, but they are again referred to in the grande ordonnance of 1498. They disappeared in the 16th century, by which time the provosts became regular officials, their office being purchasable.

Other transformations had previously taken place. The creation of the royal baillis reduced the provosts to a subaltern rank. Each bailli had in his district a certain number of provosts, who became his inferior in the official hierarchy. When appeals were instituted (and this was one of the earliest instances of their introduction) the provost, the sphere of whose competency was limited, was subject to an appeal to the baillii, though his judgment had hitherto been without appeal. Moreover, in the 14th century they had ceased to collect the revenues of the royal domain, except where the próvôts was en ferme, and royal collectors (receveurs royaux) had been appointed for this purpose. The summoning of the feudal contingents, the ban and arrière-ban, had passed into the hands of the baillis. Thus the provosts were left for their sole function as inferior judges for non-nobles, the appeals from their sentences going to the baillii, who also had jurisdiction in the first instance over actions brought against nobles and in cases reserved for the crown judges (cas royaux). This corresponded to a principle which had also applied in the chief feudal courts in the 13th and 14th centuries, where a distinction was made between judicial acts which could be performed en próvôt, and those which had to be performed in a solemn assise (assise); this did not, however, always imply the existence of a superior and an inferior official, a provost and a bailli.

The provost in the exercise of his legal functions sat alone as judge, and he alone exercised the judicial authority at his tribunal; but he had to consult with certain lawyers (avocats or procurateurs) chosen by himself, whom, to use the technical phrase, he "summoned to his council" (appelait à son conseil). In 1578 official counsellors (conseillers-magistrats) were created, but were suppressed by the ordonnance of Blois of 1570. The office was restored in 1609 by a simple decree of the royal council, but it was opposed by the parlements, and it seems to have been conferred in but few cases.

The." provosts of the marshals of France," mentioned above, were non-legal officials (officiers de la robe courue) forming part of the body of the maréchaussée which was under the ancien régime what the gendarmerie was after the Revolution. Their original function was to judge offences committed by persons following the army, but in the course of the 14th and 15th centuries they acquired the right of judging certain crimes and misdemeanours, by whomsoever committed. They became statutory, with fixed spheres of authority, and the offences falling within their competency came to be called cas prévôtaux. These were, the worst crimes of violence, and all crimes and misdemeanours committed by old offenders (reçus de justice), who were familiarly known as the giber des próvôts des maréchaux (gaol-birds). Theirs was really a kind of military jurisdiction, from which there was no appeal; but the provost was bound to associate with himself a certain number of ordinary judges or graduates in law. The provost of the marshals did not himself judge what was a cas prévôtaux; this had in each case to be decided by the nearest bailliage or presidial court. The presidial judges also dealt with cas prévôtaux in concurrence with the provosts of the marshals.

(P. E.)

**PROW**, the fore-part of a ship, the stem and its surrounding parts, hence used like "keel," by metonymy, of the ship itself. It was in old naval parlance applied to the battery of guns placed in the fore gun-deck. The Fr. prow and cognate forms (Ital. prua, Port. and Span. proa, of which the English is an adaptation) represent Lat. prara, itself adapted from Gr. πράπα, formed from πρα, before, in front. From this word must be distinguished an obsolete "prow," brave, valiant, now only surviving in the "provincial," representing O. Fr. prow, mod. proa, from the first part of Lat. prædæs, to be profitable; the same source gives "proud."

**PROXY** (short for "procuracy"), a term denoting either (1) a person who is authorized to stand in place of another, (2) the legal instrument by which the authority is conferred. Proxies are now principally employed for certain voting purposes. A proxy may in law be either general or special. A general proxy authorizes the person to whom it is entrusted to exercise a general discretion throughout the matter in hand, while a special proxy limits the authority to some special proposal or resolution. Formerly a peer could give his vote in the British parliament by proxy, by getting another peer to vote for him in his absence, temporal peers only being privileged to vote for temporal, and spiritual peers for spiritual. This voting by proxy in the House of Lords was an ancient custom, often abused. In Charles II.'s reign the duke of Buckingham used to bring twenty proxies in regular assembly and the reason was that it was ordered that no peer should bring more than two. In 1830 to 1867 inclusive proxies were only called seventy-three times; and on the 31st of March 1868, on the recommendation of a committee, a new standing order was adopted by which the practice of calling for proxies on a division was discontinued. In English bankruptcy proceedings creditors may vote by proxy, and every instrument of proxy, which may be either general or special, is issued either by the official receiver or trustee. Under the Bankruptcy Act of 1869 very great abuses of the system of proxies arose (see **BANKRUPTCY**), and were investigated by a select committee of the House of Commons. The committee recommended the abolition of general proxies; and though their recommendation was not carried out, the Bankruptcy Acts of 1883 and 1890 put considerable restrictions on the use of general proxies. A shareholder in a limited liability company may vote by proxy, and regulations to that effect prescribing the requirements, are usually embodied in the articles of association. A proxy to vote at a meeting must, by the Stamp Act 1870, bear a penny stamp. In the United States, proxies are further used for voting purposes in political conventions.

In the early practice of the admiralty courts in England a
proxy was the authority by which the proctor or advocate appeared for either party to a suit. In the ecclesiastical courts a proxy is the warrant empowering a proctor to act for the party to a suit. Two proxies are usually executed, one authorizing the proctor to institute, the other to withdraw, proceedings. They are signed by the parties, attested by two witnesses, and deposited in the registry of the court (Philimore, Ecclesiastical Law). In the convocations of the Church of England those who are absent are allowed to vote by proxy. "Proxies," or "pro-,

PRUDENTIUS, Aurelius Clemens (345-c. 410), the most remarkable of the earlier Christian poets in the West, was probably born at Tarraco, though Saragossa and Calagurris have also been claimed as his birthplace. The meagre autobiographical preface, which he affixed to the complete edition of his works when he was fifty-seven years old, makes it clear that he received a liberal education—being of noble family—practised as a lawyer and entered official life, and finally held some high office under Theodosius. At the age of fifty-seven he retired to a monastery, but died shortly afterwards.

Bentley calls Prudentius "the Horace and Virgil of the Christians," but his dictum is stilted and his metre often faulty. The list of his works given in the preface mentions the hymns, poems against the Priscilianists and against Symmachus and Peristephanon. The Diptychon or Dittochasen is not mentioned. The twelve hymns of the Cathemerinon liber ("Daily Round") consist of six for daily use, five for festivals, and one intended for every hour of the day. Prudentius shows Ambrose as his master here, but gives to Ambrose's mystic symbolism much clearer lines and more force. The Psychomachia and Homoartegas are polemic, the first against the disclaimers of the divinity of Christ, the latter against the gnostic dualism of Marcius and his followers. In them Tertullian is the source of inspiration. Of more historical interest are the two books Contra Symmachum, of 658 and 1131 hexameter verses respectively, the first attacking the pagan gods, the second directed against the petition of Symmachus to the emperor for the restoration of the altar and statue of Victory which Gratian had cast down. The Peristephanon consists of fourteen hymns to martyrs. These were mostly Spanish, but some were suggested to Prudentius by sacred images in churches or by the inscriptions of Damasus. This book, with the Cathemerinon liber and the Psychomachia, was among the most widely read books of the middle ages. Its influence on the iconography of medieval art was great. The Psychomachia is aesthetically inferior, but had the greatest influence of all of Prudentius's writings. It is the epic struggle of Christ with paganism and paganism, a struggle between the Christian virtues and the pagans. The Dittochasen is a series of quatrains, probably intended to explain forty-nine pictures of a basilica. The work is more interesting for archaeology than for literature.

Prudentius's works were published by Giselin at Antwerp in 1564, and by F. Arevalo at Rome in 1788, with complete commentary. This last is the edition reprinted in J. P. Migne's Patrologia Latina, vols. lx–lxx (Paris, 1847). More recent editions are by Orbibaris (Tübingen, 1845) and A. Dressen (Leipzig, 1886), while a critical edition was published by J. Bergmann (Leipzig, 1891).

PRUD'HON, Pierre (1758–1823), French painter, born at Cluny on the 4th of April 1758, was the third son of a mason. The monks of the abbey undertook his education, and by the aid of the bishop of Macon he was placed with Devoges, director of the art school at Dijon. In 1775 Prud'hon went to Paris armed with a letter to Wille, the celebrated engraver, and three years later he obtained the triennial prize of the states of Burgundy, which enabled him to go to Rome, where he became intimate with Canova. He returned to Paris in 1787, and led for some time a precarious existence. The illustrations which he executed for the Daphnis and Chloe published by Didot brought him into notice, and his reputation was extended by the success of his decorations in the Hôtel de Landry (now Rothschild), his ceiling painting of "Truth and Wisdom" for Versailles (Louvre), and of "Diana and Jupiter" for the Gallery of Antiquities in the Louvre. In 1808 he exhibited "Crime pursued by Vengeance and Justice" (Louvre, engraved by Royer which had been commissioned for the assize courts, and by Prud'hon's "Zephyrus" [engraved by Massard]. These two remarkable compositions brought Prud'hon the Legion of Honour; and in 1816 he entered the Institute. Easy as fortune, and consolled for his marriage by the devoted care of his excellent and charming pupil, Mlle Mayer, Prud'hon's situation seemed enviable; but Mlle Mayer's tragic suicide on the 26th of May 1821 brought ruin to his home, and two years later (Feb. 16, 1823) Prud'hon followed her to the grave. Mlle Mayer (1778–1821) was his ablest pupil. Her "Abandoned Mother" and "Happy Mother" are in the Louvre.

Volart, "Notice historique de la vie et œuvres de P. Prud'hon," in Arch. d'art français; Qu. de Quinqui, Discours prononcé sur la tombe de P. Prud'hon, Pèr. 1823; Eugène Delacroix, Rev. des deux mondes, 1835; Charles Blanc, Hist. des peintres français.

PRUNE (adapted in various forms, e.g. prunne, prunye, &c., from Fr. prune, Med. Lat. pruna, Lat. prunum, Gr. προῦνος, earlier προῦνα, plum), the name generally given to the fruit of various species of prunes, dried, and used either stewed as a dish or plain as a dessert fruit. The finest dessert prunes, known as "French prunes," are produced from the St Julien plum-tree and are dried and exported from the valley of the Loire in France. California now produces a fine quality of "prune." In scientific nomenclature, Prunus is the name of a genus of rosaceous trees, the type of the tribe prunoideae, of which the plum, apricot, peach, cherry, &c., are species (see further under Prunus). From this word must be distinguished "to prune," (1) to cut or trim superficial growth from a shrub or tree in order to encourage fresh growth and bring into regular form, &c., and (2) to trim or dress the feathers with the bill, used of a bird "preening" itself. In the first sense the word is an adaptation (16th century) of the Old French pronier, the second sense appears in the end of the 14th century but is not found in French.

PRURITUS, Pruritus characterized by intense itching of the surface of the body. It may occur in connexion with other morbid conditions, such as jaundice, diabetes, digestive disorders, &c., or as the result of the irritation produced by skin parasites. The most serious form is pruritus senilis, which affects old persons, and is often a cause of great suffering, depriving the patient of sleep. In such cases it is probably due to atrophic changes in the skin. No eruption is visible, except such marks as are produced by scratching. The treatment consists in the removal of any apparent cause, and measures to strengthen the system, such as the use of quinine, iron, &c. Soothing lotions composed of solutions of alkalys conjoined with chloral, opium, hydrocyanic acid, &c., may be applied to the affected skin at bedtime.

PRUSSIA (Ger. Preussen; Lat. Borussia), a kingdom of Germany, and the largest, most populous and most important state of the German Empire. (For map see Germany.) It is bounded on the N. by the Baltic, Mecklenburg, Denmark and the North Sea, on the E. by Russia, on the S. by Austria, the kingdom of Saxony, the Thuringian states, Bavaria and
Hesse-Darmstadt, on the W. by Alsace-Lorraine, Luxemburg, Belgium and the Netherlands. Its frontiers have a circuit of about 4,750 m., and with the exception of the enclaves Oldenburg, Mecklenburg, Brunswick and other small German states, and certain small appurtenances, such as Hohenzollern, in the south of Württemberg, it forms a tolerably compact mass of territory, and occupies almost the whole of northern Germany. Its longest axis is from S.W. to N.E. With the exception of the sea on the north and the mountain-barrier on the south-east, the frontiers are political rather than geographical. The total area of the monarchy is 134,622 sq. m. and comprises almost two-thirds of the entire extent of the German Empire. Its kernel is the mark of Brandenburg, round which the rest of the state has been gradually built up.

**Physical Features.**—Fully three-fifths of Prussia belong to the great north European plain and may be generally characterized as lowlands. The plain is much wider on the east, where only the southern margin of Prussia is mountainous, than on the west, where the Hanoverian hills approach to within less than 100 m. of the sea. A line drawn from Düsseldorf through Halle to Breslau would, roughly speaking, divide the flat part of the country from the hilly districts. In the west the Harz is separated from Austria and Bohemia by the Sudetic chain, which begins at the valley of the Oder and extends thence towards the north-west. This chain includes the Riesengebirge, with the highest mountain in Prussia, the Grosser Schneekoppe, and besides is contained in the Sudetic Lusatia. The Harz Mountains, however, beyond the Saxian plain, follow the same general direction and may be regarded as a detached continuation of the system. To the south of the Harz the Sauerland frontier intercepts the northern part of the Thuringian Forest, which is also prolonged towards the north-west by the Weser Garbbirge and the Teutoburwald. The south-west of Prussia is occupied by the plateau of the lower Rhine, including on the left bank the Dutch and on the right, and on the Taunus, the Westerwald and the Saarland. Between the lower Rhenish and Thuringian systems are interposed the Vogelsberg, the Rhön, and other hills belonging to the Thiasian system of the upper Rhine, and there are also extensive coalfields in Silesia. With the exception of the Danube Prussia is traversed by all the chief rivers of Germany, comprising almost the entire course of the Oder and the Weser. Nearly the whole of the German coast-line belongs to Prussia, and it possesses all the important seaports (see also GERMANY) except Hamburg, Bremen and Lübeck.

**Climate.**—The climate of Prussia may be described as moderate, and is generally healthy. The greatest extremes of temperature are found on the east and north, and the mean annual temperature in the black and exposed provinces of the north-east being about 41° F., while that of the sheltered valley of the Rhine is 6° higher. In winter the respective means are 26° and 35°; in summer the difference is not above 55° to 65°, and in winter the thermometer ranges from 100° to 130°, but these extremes are rarely reached. The average annual rainfall is about 21 in.; it is highest in the hilly districts on the west (34 in.) and on the north-west coast (30 to 32 in.), and lowest (16 in.) in the inland parts of the eastern provinces.

**Population.**—The following schedule shows the area and population of the whole kingdom and of each of its fourteen provinces on the 1st of December 1900, and the 31st of December 1910.

*1 Including Heligoland.

The increase of population proceeds most rapidly, as would be expected, in Berlin, and next follow Westphalia, the Rhineland, Brandenburg and Saxony, while it is weakest in Hohenzollern, Pomerania and East and West Prussia. The manufacturing districts of the Rhine, which is closely followed by the coal regions of Silesia and parts of Saxony and Westphalia. Both the birth-rate and the death-rate show a tendency to diminish. (For statistical tables under the heading of the population of the various provinces, see GERMANY.) Divided according to nationalities (by speech), the population of Prussia includes roughly 31,500,000 Germans, over 3,000,000 Poles (in the eastern provinces), 1,070,000 Lithuanians, 7,000 Danes, 5,000 Danes-Holstein, 25,000 Wends (in Brandenburg and Silesia), 25,000 Czechs (in Silesia) and 78,000 Walloons (near the Belgian frontier). In the rural districts of Posen and in parts of Silesia the Poles form the predominant element of the population.

**Communication.**—With most internal means of communication Prussia is well provided. Hardly any of its excellent highroads existed in the time of Frederick the Great, and many of them date from the Napoleonic era. The first Prussian railway was laid in 1838, but the railway system did not receive its fullest development until the events of 1866 removed the obstacles placed in the way by Hanover. Most of the lines were laid by private companies, but government control was also exercised. This system is not likely to attract private capital. In 1879, however, a measure was passed authorizing the acquisition by the state of the private railways, and in 1886 nine-tenths of the 13,800 miles of railway in Prussia were in the state's hands. The principal trunk lines of railway mileage in Prussia (5 m. per 10,000 inhabitants) is nearly as high as in Great Britain, but the traffic is much less. Between 1886 and 1896 the state-owned lines of railway increased from 9,240 m. to 18,520 m. The former total includes lines in Hesse-Darmstadt, the railways of this grand duchy having been incorporated with the Prussian railways in 1896. The building of the railways in Prussia has in almost every case been influenced by military requirements; and the happiness of the people has been secured by the trunk lines. The most important trunk line of Prussia is that which enters the western frontier at Herbesthal, and runs through Cologne, Düsseldorf, Hanover, Berlin, Dirschau and Königsberg, and leaves the eastern boundary at Eydtkuhnen for St. Petersburg. Generally speaking, the principal lines of the country either radiate from Berlin or run alongside the frontiers and boundaries. To the former category belong the lines which connect the capital with Magdeburg and Kiel, and the lines from the capital to Magdeburg with Posen and Breslau (dividing at Frankfort-on-Oder), with Dresden, Leipzig and Bavaria, with Frankfort-on-Main via Halle and Erfurt, with Coblenz via Trier, and with Cologne via Frankfort on the Main. Branch lines from Hamburg to Stettin, from Stettin to Posen and Breslau, and from Breslau to Halle; the ring is again taken up at Frankfort-on-Main, and continues up the Rhine (on both banks) to Cologne, and through Luxemburg, and thence to Liibeck; besides these there are two other important lines, one connecting Hamburg with Frankfort-on-Main via Hanover and Cassel, the other linking Hanover with Halle. Prussia possesses also an extensive system of natural and artificial waterways. In the period 1880–1893 the Prussian Government spent less than £11,677,250 upon the maintenance and construction of locks, canals, canal buildings, bridges, roads, &c. Besides there was the construction of the Dortmund-Emms Canal and the improvement of the navigation of the Oder, Vistula, Spree, and other waterways in Brandenburg. The most important of the canals are the North Sea Canal, the Elbe-Elster Canal (to connect the northern Elbe with the Elbe-Trave Canal to give Leibæk access to the Elbe), and the Dortmund-Emms Canal, and its continuation, the Dortmund-Rhine Canal (see further, GERMANY). The largest ship-owning ports are Flensburg, Stettin, Rostock, and Danzig; and Geestemünde owns the largest deep-sea fishing fleet.

**Agriculture.**—Of the total area of cultivable land in the German Empire fully 66% belongs to Prussia. About 29% of the soil of the empire consists of a mixture of sand and loam and sand mixed, 31% is predominantly sandy, and 9% is occupied by bogs and marshes. The north-eastern provinces contain a high proportion of poor soil, and in the north-west occur deposits of peat and of heath. The large forests in the north-eastern districts, as well as the soil in the neighbourhood of the rivers, are usually very fertile, and tracts of fruitful ground are found in the valleys of the Rhine and its affluents and in the plain around Magdeburg, the so-called Börde. The most fertile Prussian province is Saxony, while the least productive are East and West
PRUSSIA

The principal crop in Prussia is rye, of which the ordinary bread of the country is made; it grows in all parts of the kingdom, especially in the north-east, and occupies about one-fourth of the whole tillable surface. Oats occupy an area equal to that of barley and rye combined, and are chiefly grown in the north-eastern districts. Wheat, which is chiefly cultivated in the south and west, does not cover more than a fourth as much ground as rye. Barley is most largely grown in Saxony and Silesia. One-third of the production is consumed (chiefly for feed) in (Hanover and Schleswig-Holstein) and millet; maize is grown for fodder in some districts. The produce of grain does not cover the consumption and is supplemented by imports of rye and other cereals. The rye, cultivated for the distillation of spirits, are cultivated over nearly as large an area as rye and are especially predominant in the eastern provinces. The common beet is extensively grown for the production of sugar in Magdeburg, Hamborn, Hanover, and Posen, Saxony, and Silesia. Flax and hemp occupy considerable areas in East Prussia, Silesia, and Saxony, while hops are raised chiefly in Posen and Saxony. The cultivation of rape-seed for oil has fallen off in Saxony, Brandenburg, and Prussia, and the tobacco of Saxony, Brandenburg, Hanover and the Rhine provinces is sent to that of Germany; the annual value of Prussian-grown tobacco is about £500,000, or one-fourth of the total produce of the empire. Oilseed rape is cultivated on 33,700 acres of land, or 5 to 50 acres, 32 01% amongst farms ranging from 50 to 250 acres, and the rest amongst farms exceeding 250 acres. The provinces in which large areas (up to 2500 acres and more) are the rule, are Pomerania, West Prussia, East Prussia, West Saxony, and Saxony, in the order named. The estates of the old landed gentry (Ritterguter) of Prussia, taking the estates above 500 acres each, aggregate in all some 13,400,000 acres. Small estates (peasant homesteads) prevail in East Prussia, West Saxony, Pomerania, Brandenburg, and Westphalia, and to some extent also in Hanover, Silesia, and Saxony, but large peasant holdings (50 to 250 acres) exist only in Schleswig-Holstein, Hanover, East Prussia, Westphalia, Saxony and Brandenburg. The larger farms are more frequently to be found in the Rhine province; greater compaction of the land and absence of large areas of woods and meadows does not permit such high intensities to be offered by the progress of agricultural knowledge. One of the latest departures in this field has been the establishment of central stations for the distribution of electric power to the estates in the Rhine province, where the power is utilized for pumping in and movable machinery (mills, chaff-cutters, threshing-machines, ploughs, &c.) for lighting buildings and houses, for cooking and heating, and on large estates for giving signals and conveying hay, and is the chief cause of far-reaching effect upon Prussian agriculture, especially in the provinces of Saxony, Silesia, Posen, Hanover, West Prussia, Pomerania, Brandenburg, the Rhine province, and other parts of the kingdom, where it is i mostly practised. The most intensive cultivation of the soil and the incessant hoeing which the beet crop requires, the three or four crops which it involves, and the liability to failure from the immediately succeeding crop is to a great extent avoided. Moreover, the Prussian government has been of first-rate assistance to the Prussian farmer. Hand in hand with the cultivation of the beetroot has gone the cultivation of barley and chicory, crops of scarcely inferior value, and the production of sugar beet is grown on more than 112,000 acres. The Prussian province of Saxony is the scene of one-half of the total quantity of chicory yielded every year throughout the empire; the principal centres for its manufacture in Prussia and Saxony are Berlin and Breslau.

Livestock.—The principal breed of cattle in Prussia, with the principal government stud of Trakehnen, is the headquarters of horse breeding, and contains the greatest number of horses both relatively and absolutely. The horses bred there are generally suitable for the purposes of agriculture, and some are also used for military purposes. Horses of a stouter type are bred in Schleswig-Holstein and on the Rhine, but heavy draught horses have to be imported from France, Holland, Belgium, and Denmark. The best cattle are found in the north. The wheatlands of Hanover, they are exported in large numbers to England.

In the matter of freights the government renders material assistance to the Prussian farmer. As a result, the trade in foodstuffs and agricultural produce, especially such as is destined for export, at lower preferential rates.

Forests.—Prussia contains a greater proportion of woodland (23% of the area of Russia) than any other country in Europe (France 17%, Italy 12%, Great Britain 3%), though not so large a proportion as Russia, Austria and some of the minor German states. The most extensive forests are in East and West Prussia, Silesia, and Saxony, and in the northern and eastern districts, where oaks and beeches are the most prominent growths. The north-west is almost entirely destitute of timber, and peat is there used universally as fuel.

The government forests cover about 6,000,000 acres, or upwards of one-fourth of the whole, and are admirably managed, bringing in an annual revenue of 11 millions sterling. The state also controls the management of forests in private possession, and exerts itself to secure the greatest benefit from them.

Vickers.—The principal wine-growing districts of Prussia are the Rhinegau and the Rhine provinces, though wine is also produced in Silesia, Westphalia and a few other districts. The valleys of the Elbe, the Oder, and the Saale, have a reputation for excellent wine. The Prussian state owns several vineyards in the Rhinegau. German vine-growers have, in common with vine-growers in other countries of Europe, from the Oldtum Tucker and the Prussian vine-grower, has spent large sums of money in endeavouring to arrest the ravages caused by mildew.

Fisheries.—The fisheries on the Baltic Sea and its hafns, and on the North Sea, are important. In the former the take consists mainly of herring, with flat fish, salmon, mackerel and eels, while the chief objects of the latter are invertebrates. Fishing is promoted by the foundation of numerous piscicultural establishments and by the enactment of close-time laws. Carp, perch, pike and salmon, the last-named especially in the Rhine, are the principal varieties; among the estuaries, the marshes, lagoons and salt marshes of the North Sea, the Kattegat and the Baltic, as well as the waters of the Elbe and Weser, are devoted to the fishery. Oysters have been imported from France, and shell-fish are imported from Holland. The annual production of fish is 300,000 tons, chief among which are salmon, pollock, oysters, clams, and shell-fish.

The most important fishery is that for herring, which is prosecuted on a large scale in the Baltic Sea; the annual production is 12 million tons, chiefly from the waters of the Baltic and the Kattegat.

The salmon fishery is carried on mainly in the North Sea, and the annual catch is 340,000 tons, chiefly from the waters of the North Sea and the Kattegat.

The most important fishery is that for herring, which is prosecuted on a large scale in the Baltic Sea; the annual production is 12 million tons, chiefly from the waters of the Baltic and the Kattegat.
promoted by the commercial and fiscal policies of his government. The chief industrial districts are, of course, those which yield coal, with, in addition, the great cities—Berlin, Magdeburg, Hanover, Breslau, Görlitz, Stettin, Essen, Dortmund, Elberfeld-Barhen, Duisburg, Düsseldorf, and the Rhine province. In the Ruhr province, Frechen, Frankfort-on-Main, Saarbrücken, Höchst, Solingen, Remscheid, Hagen, Königsberg, Danzig and many others. The iron and metal industries, especially the making of machinery, electrical plant, transformers, and the production of articles in wrought copper and brass, rank in the forefront. In these branches Berlin, and more lately its suburbs, as well as Magdeburg and Cologne, have played an active rôle, though the old centres of the metallurgical and iron and steel industries in the Rhine province, Hohenzollern, and Diisseldorf, have also expanded in an extraordinary degree. The growth of the chemical industries, which are essentially a German speciality, must also be mentioned in the front rank. The branches in which this industry has proved particularly successful are dyes, artificial indigo, illuminates (acetylene gas, Welsbach mantles, &c.), explosives, various chemical salts, pharmaceutical preparations, cellulose, glycine, artificial (chemical) manures, and perfumes. A third branch of industry in which German genius has won triumphs of the highest kind is shipbuilding.

Constitution.—The present constitution of Prussia was framed by the government of King Frederick William IV. with the cooperation of a constituent assembly, and was proclaimed on the 31st of January 1850. It consists of an hereditary monarchy with two houses of parliament and was subsequently modified by various enactments, notably that of the 12th of October 1854, reconstituting the chambers of representatives and senators. It contains, in the first part, a declaration of the rights of all citizens in the eye of the law, provides for universal military service, and guarantees the personal liberty of the subject, the security of property, immunity from domiciliary visits, the inviolability of correspondence, the liberty of speech, the right of association and public meetings, and liberty of migration.

The monarchy is hereditary in the male line of the house of Hohenzollern-Preussen. The king alone exercises the executive power, has the supreme command of the army, and is head of the Church, but shares the legislative power with his parliament. He appoints and discharges the ministers of state, and is chairman of the Council of State. He is also commander-in-chief of the army. The king possesses the right of pardon and mitigation of punishment, declares war and concludes peace, confers orders and titles and conducts the foreign policy of the country, though this prerogative has been exercised by his ministers. The king is the representative of the German emperor. He is held to be irresponsible for his public actions, and his decrees require the countersign of a minister, whose responsibility, however, is not very clearly defined. The national tradition and feeling lend the Crown considerable power not formulated in the constitution, and the king is permitted to bring his personal influence to bear upon parliament in a way quite at variance with the English conception of a constitutional monarch. The king appoints the Cabinet, which has for its term of office 1854.

The legislative assembly or Landtag, consists of two chambers, which are convoked annually at the same time but meet separately. The right of proposing new measures belongs equally to the king and the two chambers, or to either of them. The king may, however, before a measure can pass into law. The chambers have control of the finances and possess the right of voting or refusing taxes. Financial questions are first discussed in the lower house, and the upper house either accepts or rejects the budget only in bloc. All measures are passed by an absolute majority, but those affecting the constitution must be submitted to a second vote after an interval of at least twenty-one days. Members may not be called to account for their parliamentary utterances except by the chamber in which they sit. No one may at the same time be a member of both chambers. The ministers of the Crown have access to both chambers and may speak at any time, but they do not vote unless they are actually members. The sittings of both chambers are public.

The general scheme of government, though constitutional, is not exactly parliamentary in the English sense of the word, as the choice of the ministers is not, as in England, subject to the opinions of the parliamentary majority. The Herrenhaus, or house of peers, contains two classes of members, the hereditary and non-hereditary. The former consists of the adult princes of the house of Hohenzollern, the members of the Senate, and the heads of the old imperial nobility; and the heads of the great territorial nobility. The members are chosen for life by the king from the ranks of the rich landowners, manufacturers and men of property in general. They are elected, if they are not already members by the king's approval by the landowners of the eight old provinces, by the larger towns and by the universities. Every member of the Herrenhaus must be specially summoned by the king. The Abgeordnetenhaus or chamber of deputies, consists of 433 members, elected for periods of five years by indirect suffrage, exercised by all male citizens who have reached the age of twenty-five and have not forfeited their communal rights. The original electors are arranged in three classes, according to the rate of taxes paid by them, in the 4th class, which consists of the citizens of the capital city, and the members of each class. The country is accordingly divided into electoral districts, with the electors grouped in three categories, each of which selects a Wahlmann or electoral proxy, who exercises the direct suffrage. They elect those who represent the electors in their various districts, who are in possession of their civic rights. They receive a daily allowance (Diensten) during the sitting of the house, and traveling expenses.

The king exercises his executive functions through an irresponsible Staatsrat, or privy council, revived in 1884 after thirty years of inactivity, and by a nominally responsible cabinet or council of ministers (Staatsministerium). The latter consists of ministers of war, and foreign affairs, and ministers of justice, finance, the interior, public worship and instruction, industry and commerce, public works and agriculture, domains and forests. Ministers conduct the affairs of their special departments in council. The discussion of constitutional questions. They represent the executive in the houses of parliament and introduce the measures proposed by the Crown, but do not need to belong to either chamber. The affairs of the royal government are conducted by a cabinet of ministers, each of whom is assisted by a privy council. The provisions of the constitution for Herrenhaus and Repräsentantenhaus remain in full force.

Justice.—Down to the 1st of January 1900 (when the German civil code—Bürgerliches Gesetzbuch—was introduced) a threefold system of law had prevailed in Prussia, viz. the common law of Prussia (Landrecht), codified in 1794, in eastern and central
PRUSSIA

Prussia, the German common law (Gemeines deutsches Recht) in Schleswig-Holstein, Hanover, and parts of the Rhine provinces, and the Code Napoléon generally on the Rhine and in Alsace-Lorraine.

The bürgerliches Gesetzbuch has now put an end to the former anomalous legal law was unified by the penal code (Strafgesetzbuch) of 1871 and the military penal code (militärisches Strafgesetzbuch) of 1872. A new penal code, promulgated in 1850, did away with the old patrimonial or seignorial jurisdiction, and the administration of justice in the provinces. The government of lowest instance are the Amtsgerichte, in which sits a single judge, accompanied in penal cases by two Schöffen or lay assessors (a kind of juryman, who vote with the judge). Cases of more importance are decided by the Landgerichte or county courts, in which the usual number of judges is three, while in important criminal cases a jury of twelve persons is generally empanelled. From the Landgerichte appeals may be made to the Oberlandesgerichte or provincial courts, which sit at Posen, Berlin, and Breslau, and form the highest tribunals of the empire, and the Landgericht with its jurisdiction, and forms the final instance for summary convictions in Prussia, whilst all other cases may be taken to the supreme imperial court at Leipzig. The judges (Richter) are appointed and paid by the state, and hold office for life. After finishing his university career the student of law who wishes to become a judge or to practice as qualified counsel (Rechtsanwalt, barrister and solicitor in one) passes a government examination and becomes a Referendarius. He then spends at least four years in the practical work of his profession, after which he passes a second examination, and, if he passes the second examination of the judge, he is given a position in the municipal or provincial courts, as judge of the lower courts, or as a member of the Landgericht. The number of judges of the Landgericht in the empire is limited to 2,550, and there are also 2,782 minor judges and assessors.

Religion.—The centre of the kingdom is solidly Protestant, the proportion of Roman Catholics increasing towards east and west and reaching its maximum on the Rhine and in the Slavonic provinces. East Prussia is entirely Protestant, while the western territories are divided between the two religions. The Roman Catholics greatly outnumber the Protestants in the Rhine provinces (3 to 1), Posen, Silesia and West Prussia. All religious bodies are granted freedom of worship, and civil rights are enjoyed by them. The Evanglical or Protestant State Church of Prussia consists of two archbishops (Cologne, Gnesen-Posen) and ten bishops. The prince-bishop of Brüssel and the bishops of Ermeland, Hildesheim and Osnabrück are directly under the pope, and the bishoprics of Paderborn, Utrecht, Münster, and Osnabrück are represented by the Catholic princes in Baden. The higher ecclesiastics receive payment from the state, and the annual appropriation appearing in the budget for the Roman Catholic Church is as high as that made for the State Church. The imperial Church in Germany is organized in the imperial See of Rome, but its sovereignty has been suppressed except those occupied with attendance on the sick.

The relations of the State with the dissenting Churches, such as the Baptists, Mennonites, and Moravians in Branden, are practically confined to granting them charters of incorporation which ensure them toleration. The Mennonites were formerly allowed to pay an extra tax in lieu of military service, which was income from their beliefs, but this privilege has been withdrawn. The Old Catholics number about 30,000, but do not seem to be increasing.

The Jews belong mainly to the urban population and form 20 to 30% of the inhabitants in some of the towns in the Slavonic provinces. (For more exact details of the various religious creeds, see Germany.)

Education.—In Prussia education is compulsory, and the general level attained is very high. Every town or community must maintain a school, supported by local rates and under the supervision of the government. The elementary school must be permitted to instruct, or to found teaching establishments, provided they can produce to the authorities satisfactory proofs of their moral, scientific and technical qualifications. Both public and private schools are supported by public grants, and are under the control of public instruction, and all public teachers are regarded as servants of the state (Staatsbeamte). No compulsion exists in reference to a higher educational institution than primary schools. All children of school age are at present of necessity required to attend school, but they are not required to attend the higher grades of secondary education. At the head of the administration stands the minister of public instruction and ecclesiastical affairs, to whom also the universities are directly subordinated. The higher (secondary) schools are regulated by a joint board of education appointed by the government, while the management of the lower grades is left to the police. The higher primary schools and private schools fall within the jurisdiction of the ordinary Regierungen or civil government. This is carried out through qualified school inspectors, frequently chosen from among the clergy.

The expenses of the secondary schools are borne by the communes (Gemeinden), aided when necessary by subsidies from the state. The subjects of instruction are theology, reading, writing, spelling, arithmetic, the elements of geometry, history, geography, and the liberal arts, and to these are added, in two years.

The secondary schools of Prussia may be roughly divided into classical and modern, though there are comparatively few in which the subject matter is all public instruction in Latin and Greek, preparing pupils for University. The classical form of education is provided by the Gymnasium and Progymnasia, the latter being simply gymnasium wanting the higher classes. In these boys are prepared for the universities and the learned professions, and the full course lasts for nine years. In the modern schools, which are divided in the same way into Realgymnasium and Realsprogymnasia, the students have a nine years' course, Latin is taught, but not Greek, and greater stress is laid upon modern languages, mathematics and natural sciences. The technical schools are practically identical with those of the gymnasium, with the exception that the length of training is assimilated as closely as possible to that of the classical schools, with the subjects somewhat altered. Among the technical schools are the Oberrealschulen, which chiefly prepare for the engineering schools. In the modern schools, these secondary schools possess the right of granting certificates entitling the holders, who must have attained a certain standing in the school, to serve in the army as one-year volunteers. The teachers in the modern schools are generally women, and the certificate of 'ripeness' (Maîtrisesgraden), in indicating that the holder has passed satisfactorily through the highest class, entitles a student to enroll himself in any faculty at the university, but that the real gymnasium qualifies only for the general or so-called "facultal" faculties. As a rule, the student must be prepared at a cost seldom exceeding, in the highest classes, £5 per annum. The teachers are of higher school and are from the higher secondary schools. The grade of the secondary schools has been established and endowed by municipal corporation.

Prussia possesses ten of the twenty German universities (not including the lyceum at Braunsberg and the Roman Catholic seminary at Münster). The largest Prussian university is that of Berlin, and then comes the University of Münster and Halle are the next in size. The oldest is the university of Göttingen, founded in 1737. Like the schools the universities are state institutions, and the professors are appointed and paid by government, which also makes liberal annual grants for apparatus and equipment. The full obligatory course of study extends over three, and in the case of medicine, four years. It is, however, not usual for non-medical students also to spend four years at the university, and there is an agitation to make this compulsory. Students qualifying for
a Prussian government appointment are required to spend at least three terms or half-years (Semester) at a Prussian university.

Ranking with the universities are the large technical high schools at Berlin, Hanover, Aix-la-Chapelle and Danzig, the mining academies of Berlin and Knausbir, and the agricultural high schools of Berlin and Poppelsdorf (Bonn) and the two veterinary high schools of Berlin and Hanover. Music is taught at several conservatoria, the best known of which are at Berlin and Frankfort-on-Main.

This year Prussia had their next most conspicuous internal expression in the academies of science and art at Berlin, both founded by Frederick I.; and each town of any size throughout the kingdom has its antiquarian, artistic and scientific societies. Recorded schools of painting exist at Berlin, and Düsseldorf, and, both these towns, as well as Cassel, contain excellent picture galleries. The scientific and archaeological collections of Berlin are also of great importance. Besides the university collections, there are many important public libraries, the chief of which is the royal library at Berlin (1,000,000 volumes).

Finance.—As in all civilized countries, the national accounts of Prussia expand by leaps and bounds, and they do this in spite of the advantage which the state derives from the possession of valuable revenue yielding properties. Of these the most important are the railways. Next in point of revenue come the mines and salines. Then follow the state forests and the landed domains, though the income from this source is rapidly decreasing as agriculture increases. The revenue from the principal sources of revenue were estimated at £135,914,080. The principal sources of revenue are the railways, £21,908,493: domains and forests, £5,982,911; state lottery, £4,640,065; mines, etc., £1,485,875; direct taxation, £1,580,135: indirect taxation, £1,779,965; administrative receipts, £4,610,884; and from the general financial control, £8,386,636. The chief items of the expenditure consist of payments for religion and education, £8,201,350; justice, £6,260,330; working expenses, including £50,286,525 for working the state railways, £69,626,542; interest, etc., on public debt, £1,375,380; the ministry of finance, £6,565,772; and the ministry of the interior, £4,313,780. The public debt was £643,360,591 in 1862 to £669,417,644 in 1905. The greater part of this debt has been incurred in the purchase of the state railways.

See Jahrbuch für die amtliche Statistik des preussischen Staates, the annual statistical year-book for and by network and administrative data of the statistical offices of Prussia and Germany. General accounts of the natural, social and political features of the country are given in Eiselen's Der preussische Staats (Berlin, 1862) and in Daniel's Handbuch der Geographie (several editions). The Prussian constitution and administrative system are concisely described in the Handbuch der Verfassung und Verwaltung in Preussen, by Graf Huit de Grais, and are treated at length in Von Rönne's Staatsrecht der preussischen Monarchie (4th ed., 1881-1894), and in Armbrust, Karl Adolph, Grundzüge für das Verwaltungsrecht in Preussen (Berlin, 1890). In addition, see Landes- und Preussens (Berlin, 1901), edited by Beuermann. Various volumes of Forschungen zur deutschen Landes- und Volkskunde, edited by Kirchhoff: British Diplomatic and Consular Report, and James Baker, Report on Technical and Commercial Education in East Prussia, &c. (London, 1900).

History.—The name of Prussia is derived from the dukedom of Prussia (the present province of East Prussia), which was raised into a kingdom by the emperor in favour of Frederick III., elector of Brandenburg, on the 18th of January 1701. The title "king of Prussia"1 applied at the outset only to Prussia proper, which formed no part of the Empire; in respect of his other dominions the king continued to bear titles (margrave, duke, &c.) which implied feudal subordination to the emperor. The extension of the style "kingdom of Prussia" so as to cover the whole of the territories, by whatever title held, of the electors of Brandenburg, was not, however, an empty assumption, but symbolized a new fact of first-class historic importance: the rise in Germany and in Europe of a new great power. The consolidation of this power had been the work of the Great Elector. After the death of the Elector in 1640, he laid the founda-tion of the modern Prussian state (see Frederick William I. Elector of Brandenburg and Brandenburg: History).

The Great Elector's son Elector Frederick III. was an ostentatious and somewhat frivolous prince, who hazarded the acquisitions of his father by looking on his position as assured and by aiming rather at external tokens of his dignity than at a further consolidation of the basis on which it rested.

Frederick I., 1688-1713.

Frederick II. William I. 1713-1740.

Frederick I., 1688-1713.

Frederick II. William I. acceded on the 13th of May 1713, Prussia received upper Gelderland in exchange for the principality of Orange, and the king's title was acknowledged by the European powers.
Prussia

state of Europe, though his administration was of a purely arbitrary type, in which the estates were never consulted and his ministers were merely clerks to register his decrees. His first act was to reform the expensive institutions of the court; and the annual allowance for the salaries and pensions of the chief court officials and civil servants was at once reduced from 276,000 to 55,000 thalers. The peace of Utrecht (1713) left Frederick William free to turn his attention to the northern war then raging between Sweden on the one side and Russia, Poland, and Denmark on the other. Though at first disposed to be friendly to Sweden, he was forced by circumstances to take up arms against it. In September 1713 Stettin was captured by the allies and handed over to the custody of Frederick William, who paid the expenses of the siege and undertook to retain possession of the town until the end of the war. But Charles XII. refused to recognize this arrangement and returned from his exile in Turkey to demand the immediate restitution of the town. At this demand the king of Prussia declared it could not comply, unless the money he had advanced was reimbursed; and the upshot was the outbreak of the only war in which Frederick William ever engaged. The struggle was of short duration, and was practically ended in 1715 by the capture of Stralsund by the united Prussians, Saxons and Danes under the command of the king of Prussia. The Swedes were driven from Pomerania, and at the peace of 1720 Frederick William received the greater part of Swedish Pomerania, including the important seaport of Stettin. Sweden now disappeared from the ranks of the Great Powers, and Prussia was left without a rival in northern Germany.

A detailed history of Frederick William's reign would necessitate the recital of a long and tedious series of diplomatic proceedings, centreing in the question of the succession to the duchies of Julich and Berg. The treaty of Westminster between Austria and France in 1716, which was later confirmed with some modifications by the treaty of Berlin in 1728, Frederick William engaged to recognize the Pragmatic Sanction, and the emperor on his side undertook to support Prussia's claims to Julich and Berg. The policy of the latter, however, was far from straightforward, as he had already entered into a similar compact with the count palatine of Sulzbach, who was a Roman Catholic and therefore a more sympathetic ally. Frederick William's intervention in the matter of the succession to the throne of Poland, rendered vacant by the death of Augustus II. in 1733, proved barren of advantage to Prussia and failed to secure the hoped-for reversion of the duchy of Courland. A Prussian contingent took part none the less in the ensuing war between Austria and France, but Austria concluded peace in 1735 without consulting her ally. In 1737 the king withstood the pressure brought to bear upon him by England, France, Holland and Austria to induce him to submit to their settlement of the Julich-Berg question; and in 1739, convinced at least of the confirmed duplicity of the emperor, he turned to his hereditary enemy for help and concluded a defensive alliance with France. The rivalry between Austria and Prussia had begun, which for the rest of the century formed the pivot on which the politics of Europe mainly turned.

If the external history of Frederick William's reign is not especially glorious, and if in diplomacy he was worsted by the emperor, the reasons were partly in the nature of his state, in which the discipline was low, the army small, and the administration inefficient. The years' peace and efficient government. During this reign the revenues of Prussia were doubled, and the king left at his death an accumulated treasure of 9,000,000 thalers, and an army of 80,000 men. Though not ranking higher than twelfth among the European states in extent and population, Prussia occupied the fourth place in point of military power. The king himself took the greatest interest in the maintenance of his army, which he knew to be his mainstay, and he carried the habits of the military martinet into all departments of the administration. His chief innovation was the abolition of the distinction between the military and the civil funds, and the assumption by him of the entire financial management of the country under a general directory of finance, war and domains. The directory was instructed to pay for everything out of a common fund, and so to regulate the expenditure that there should invariably be a surplus at the end of the year. As the army absorbed five-sevenths of the revenue, the civil administration had to be conducted with the greatest economy. The king himself set the example of the frugality which he expected from his officials, and contented himself with a civil list of 52,000 thalers (£7800). The domains were now managed so as to yield a greater income than ever before, and improvements of every kind were introduced in the system of taxation. By the substitution of a payment in money for the obsolete military tenure the nobles were deprived of their practical exemption from taxation, and they were also required to pay taxes for all the peasant holdings which they held in fee. The condition of the peasants, and the worst features of villeinage were abolished in the Crown's domains. The military system of cantonment, according to which each regiment was allotted a district in which to recruit, was not, however, carried out in detail, and the peasants were brought in direct contact with the royal officials. The collection of the taxes of the peasantry was removed from the hands of the landowners. The duties of the state officials were laid down with precision, and their performance was exacted with great severity. Justice seems to have been administered in an upright manner, though the frequent and often arbitrary infliction of the penalty of death by the king strikes us with astonishment. The agricultural and industrial interests of the country were treated with great zeal. The most important industrial undertaking was the introduction of the manufacture of woolen cloth, the royal factory at Berlin supplying uniforms for the entire army. The commercial regulations, conceived in a spirit of rigid protection, were less successful. In the ecclesiastical sphere the king was able to secure toleration for the Protestants in other parts of Germany by reprisals on his own Roman Catholic subjects, and he also gave Weld to many religious ordinances. He visited the exiled peasants from Salzburg (1732). He has the credit of founding the common-school system of Prussia and of making elementary education compulsory.

On the 31st of May 1740 Frederick William died, and was succeeded by his son as Frederick II., known in history as Frederick the Great. The young king at once resolved to use the well-filled treasury and well-disciplined army left to him by his father for the purpose of increasing the position of Prussia in Europe. The death of the emperor Charles VI., the last of the male line of the house of Habsburg, on the 20th of October 1740, gave him his opportunity, by raising the question of Maria Theresa's rights to succeed under the Pragmatic Sanction (see Charles VI., emperor; Maria Theresa; Austria-Hungary: History). Austrian duplicity in the matter of Jülich gave him a colourable pretext for his hostile attitude in reviving the long dormant claims of Prussia to the Silesian duchies. Within a year of his accession he had embarked on the Silesian War, and this was closely followed by the second, which ended in 1745, leaving Frederick in undisputed possession of almost the whole of Silesia, with the frontier that still exists. East Friesland, the Prussian claim to which dated from the time of the Great Elector, was absorbed in 1744 on the death without issue of the last duke. The two Silesian Wars completely exhausted the stores left by Frederick William, both of grenadiers and thalers, and Frederick gladly welcomed the interval of peace to amass new treasures and allow his subjects time to recover from his exertions. When the Seven Years' War broke out in 1756 he had an army of 150,000 men at his command, representing about one-seventh of the available male population of his little kingdom. He had also a fund of 11,000,000 thalers in his treasury, though this would have gone but a small way had he not been assisted by the subsidies of England and able to make the fertile plains of Saxony his chief basis of supply. (See Seven Years' War.)

Though without gain in extent or population, Prussia emerged from the war as an undoubtedly power of the first rank, and henceforth completely eclipsed Saxony, Bavaria and Hanover. Frederick's military and financial administration made the country without a rival for the hegemony of the German Empire. The glorious victories over the French and Russians also awakened a spirit of German patriotism that had hitherto been almost unknown in the German states. The result was enormous. Of the 850,000 soldiers who, as is estimated, perished during the war about 180,000 fell in the service of Prussia, and the gross population of the kingdom had decreased in seven years to within one-tenth of its pre-war number. The material loss attendant on the war was incalculable. The development of the country was thrown back for many years, which were almost a repetition of the period succeeding the Thirty Years' War. But while nearly a century elapsed before the traces of that struggle disappeared, Frederick repaired most of the ravages of the Seven
Years' War in a tenth of the time. By great dexterity in the management of his finances he had kept clear of debt, and was soon able to advance large sums to the most impoverished districts. Foreign colonists were invited to repopulate the deserted villages; taxes were in some cases forgiven for the first year; large numbers of the army were employed in farm labour; and individual effort in every department was liberally supported by the government. By 1770 nearly all the ruined villages had been rebuilt; the ground was again fertile; the conqueror had paid the conqueror who had been filled; and the debased currency had been called in.

Throughout the kingdom agriculture was encouraged by the drainage of marshy districts; industry was extended by the introduction of new manufactures, by bounties and by monopolies; and commerce was fostered by measures of protection. Frederick's methods of administration did not greatly differ from those of his predecessor, though the unremitting severity of Frederick William was relaxed and the system was in many respects improved under his personal supervision extended to every department, and his idea of his position and duties made him his own first minister in the widest and most exacting sense of the term. His efforts to improve the administration and the bureaucracy were unceasing, and he succeeded in training a body of admirable public servants. One of his most sweeping reforms was in the department of law, where, with the able aid of the jurist Samuel von Cocceji (1679–1755), he carried out a complete revolution in procedure and personnel. One of the king's first acts was to abolish legal torture, and he rarely sanctioned capital punishment except in cases of murder. The application of the privilegium de non appellatione (1746) freed Prussia from the ancient ritual with which the country had hitherto had to find a way for a codification of the common law of the land, which was begun under Frederick but not completed till the end of the century. In matters of religion Frederick not only exercised the greatest toleration, remarking that each of his subjects might go to heaven after his own fashion, but distinctly disclaimed the connexion of the state with any one confession. Equal liberty was granted in speaking and writing. Though his finances did not allow him to do so generously, Frederick greatly enhanced his example of the custom of men of letters exercising a most salutary effect. The old system of rigid social privilege was, however, still maintained, and unsurmountable barriers separated the noble from the citizen and the citizen from the peasant. The paramount defect of Frederick's administration, as future events proved, was the neglect of any effort to encourage independence and power of self-government among the people. Every measure emanated from the king himself, and the whole country learned to rely on him alone for help in every emergency.

In 1772 Prussia and Austria, in order to prevent an overweening growth of Russia, joined in the first partition of Poland. Frederick's share consisted of West Prussia and the Netze district, which filled up the gap between the great mass of his territories and the isolated district of East Prussia. It had also this advantage over later acquisitions at Poland's expense, that it was a thoroughly German land, having formed part of the colonies of the Teutonic Order. In 1778 Prussia found herself once more in opposition to Austria on the question of the partition of Poland, but this question was adjusted without much bloodshed (see Potato War). The same year elicited the last action of importance in which Frederick engaged—the formation of a "Fürstenbund," or league of German princes under Prussian supremacy, to resist the encroachments of Austria. The importance of this union was soon obscured by the momentous events of the French Revolution, but it was a significant foreshadowing of the duel of Austria and Prussia for the pre-eminence in Germany. Frederick died on the 17th of August 1786, having increased his territories to an area of 75,000 sq. m., with a population of five and a half millions. The revenue also had immensely increased and now amounted to about twenty million thalers annually, of which, however, thirteen were spent on the army. The treasury contained a fund of sixty million thalers, and the country was free of debt. (See Frederick II, King of Prussia.)

A continuation of the personal despotism under which Prussia had now existed for seventy years, as well as of its dispropor-
tionate influence in Europe, would have required a Frederick William II., ruler with something of the iron will and ability of 1786-1797. Frederick the Great. Unfortunately Frederick's nephew and successor, Frederick William II., had neither the energy nor the insight that his position demanded. He was too undecided to adhere to the vigorous external policy of his predecessor, nor did he on the other hand make any attempt to meet the growing discontent by an internal movement of liberal reform. The rule of absolutism continued, though the power now lay more in the hands of a "camarilla" or cabinet than in those of the monarch; and the statesmen who now came to the front were singularly short-sighted and inefficient. The freedom of religion and the press left by Frederick the Great was abrogated in 1788 by royal ordinance. In 1787 the army engaged in an expensive and useless campaign against Holland. The abandonment of Frederick's policy was shown in a tendency to follow the lead of Austria, which culminated in an alliance with that power against revolutionary France. But in 1795 Prussia, suspicious of the Polish plans of Russia and Austria, concluded the separate peace of Basel, almost the only redeeming feature of which was the stipulation that all north German states beyond a certain line of demarcation should participate in its benefits. This practically divided Germany into two camps and inflicted a severe blow on the imperial system. The indifference with which Prussia relinquished to France German lands on the left bank of the Rhine, compared with her eagerness to increase her Slavonic territories on the east, was certainly one of the great blunders of the reign. Prussia's share in the second and third partitions of Poland (1793 and 1795) nearly doubled her extent, but added little or nothing to her real power. The twelve years following the peace of Basel form one of the most sombre periods of the history of Prussia. Her prestige was lost by her persistent and ill-timed neutrality in the struggle with France; the old virtues of economy, order and justice disappeared from the bureaucracy; the army was gradually losing its excellence and was weakened rather than strengthened by the hordes of disaffected Polish recruits; the treasury was exhausted and a large debt incurred; the newly awakened feeling of German patriotism had died away, especially among the upper classes. (See Frederick William II., King of Prussia.)

Frederick William III. possessed many virtues that did him credit in his private capacity, but he lacked the vigour that was at this juncture imperatively required from a ruler of Prussia, while he was unfortunately surrounded by counsellors who had as little conception as himself of Prussia's proper role. Not even the high-handed occupation of Hanover by the French in 1803 could arouse him; and the last shred of self-respect seemed to have been parted with in 1805 when Prussia consented to receive Hanover, the property of its ally England, from the hands of France. The formation of the Confederation of the Rhine in 1806 and the intelligence that France had agreed to restore Hanover to England at last convinced Frederick William of what he had to fear from Napoleon; while Napoleon, on his side, being now free of his other antagonists, was only too glad of an opportunity to destroy his tool. Prussia declared war on the 9th of October 1806; and the short campaign that ensued showed that the army of Frederick the Great had lost its virtue, and that Prussia, single-handed, was no match for the great French commander. On the 14th of October the Prussian armies were overthrown at Jena and Auerstädt, and a total collapse set in. Disgraceful capitulations of troops and fortresses without a struggle followed one another in rapid succession; the court fled to East Prussia; and Napoleon entered Berlin in triumph. At the Peace of Tilsit (July 9, 1807) Frederick William lost half his kingdom, including all that had been acquired at the second and third partitions of Poland and the whole of the territory west of the Elbe. An enormous war indemnity was also demanded, and the Prussian fortresses were occupied by the French until this should be paid. The next half-decade was a period of the greatest significance in the history of Prussia, embracing, as they do, the turning-point in the moral regeneration of the country. The disasters of 1806 elicited a strong spirit of patriotism, which was fanned by the exertions of the "Tugendbund," or League of Virtue, and by the writings of men like Fichte and Arnold. The credit of the reformation belongs mainly to the great minister Stein, and in the second place to the chancellor Hardenberg.
The condition on which Stein based his acceptance of office was itself of immense importance; he insisted that the system of governing through irresponsible cabinet coun-
cillors, which had gradually become customary, should cease, and that the responsible ministers of
departments should be at once the confidential advisers and the executive agents of the king. Stein’s edict of 1807 abolished serfdom and obliterated the legal distinction of classes by establishing freedom of exchange in land and free choice of occupation. The “Städeordnung” of 1808 reformed the municipalities and granted them important rights of self-government. His administrative reforms amounted to a complete reconstruction of the ministerial departments and the machinery of provincial government, and practically established the system now in force. In 1810 Hardenberg, with a precipitancy which Stein would scarcely have approved, continued the reform in the condition of the peasants by making them absolute owners of part of their holdings, the landlords obtaining the rest as an indemnity for their lost dues. The army was also reorganized by Scharnhorst and Gneisenau, while the condition imposed by Napoleon that it should not exceed 42,000 men was practically evaded by by-passing the 1806 conscription decrees and, after both were revoked, it was fairly seized in military exercises. The educational reforms of Wilhelm von Humboldt established the school system of Prussia on its present basis, and the university of Berlin was founded in 1809 (see STEIN, H. F. C. FREIHERN VON; HARDENBERG, K. A. VON).

Frederick William hesitated to take part in the Austrian rising in 1809, but his opportunity came in 1813, when Napoleon fled from Russia. General York, commander of the corps that Prussia had been obliged to contribute to the French expedition, anticipated the formal declaration of war by joining the Russians with his troops on his own responsibility (Dec. 30, 1812). On the outbreak of the war the people rose en masse and with the utmost enthusiasm. A treaty of alliance between Russia and Prussia was concluded at Kalisch, and Austria, after some hesitation, also joined the league against Napoleon. In the struggle that followed (see NAPOLEONIC CAMPAIGNS) Prussia played one of the most prominent parts and, her general Blücher was the driving force of the allied armies. Between 1813 and 1815 the battle of Waterloo Prussia lost 174,000 men, and strained her financial resources to the utmost. As compensation she received at the Congress of Vienna the northern half of Saxony, her old possessions west of the Elbe, Swedish Pomerania, the duchies of Berg and Jülich, and other districts in Westphalia and on the Rhine. The acquisitions of the last partition of Poland, with the exception of the grand-duchy of Posen, were assigned to Russia; Friesland went to Hanover, and Bavaria was allowed to retain Baireuth and Ansbach, which had come into her hands in 1806. This arrangement of the map did not wholly restore Prussia to its former extent, as its area was now only 108,000 sq. m. compared with 122,000 sq. m. at the beginning of 1806, but the substitution of German for Slav territory and the shifting of the centre of gravity towards the west more than made up for any slight loss in size. Hanover still formed a huge wedge splitting Prussia completely in two, and the western frontier was very ragged. Prussia’s position required caution, but forced upon it a national German policy; and the situation of the new lands was vastly more effectual in determining the future leader of Germany than was Austrian’s acquaintance in it.

The task that confronted Frederick William III. in 1815—that of welding together the heterogeneous elements assembled under his crown by the great congress—was one that would have taxed the statesmanship of a stronger man than he. The electorate of Posen had been more than doubled, and contained, besides 2,000,000 Slavs, people of every German race; and, as an additional problem, the annexation of the Rhine provinces had raised the number of Roman Catholic subjects of the most Protestant of the German monarchs to some two-fifths of the whole. On the 3rd of June 1814 the king had issued a cabinet ordinance establishing a Prussian Diet on a national constitutional, and this promise had been repeated in proclamations at Danzig and Posen (May 9, 1815) and in the patent addressed to the new Saxons promised on the admission of Saxony to the federal estates there was to be a national Diet for the whole country. When, however, the work of drawing up the constitution was put in hand, it soon became clear that it would meet with extraordinary difficulties. The personal influence of Metternich, one of the leaders of the new system, partly through the circumstances of the period, but partly through his own strong feudal spirit, and the new western provinces, in which the ideas of the Revolution had gained a permanent ascendency; and of all these conflicting tendencies, one only was organized into a compact body of lasting value. The university of Jena (July 10) became the mark of Brandenburg, "heartless, wooden, half-educated people," as Steib called them, "fit only to be turned into corporals or calculating machines," but for all that the very backbone of the German People had been broken.

In spite of all the king would probably have granted a constitution, but for the ill-timed alarms and excursions of the Liberal Turnvereine and Burschenschaften. The trials and humiliations of Poland had paralysed the national spirit; in this epoch had left him in a condition of nervous apprehension, which was not, however, till the 11th of June 1821 that the king agreed to create a liberal diet. Thereupon a commission was appointed to organize a system of provincial estates, which were created by royal patent on the 5th of June 1823. For the rest, the question of a constitution was not again raised during the king’s reign, and for years the Prussian police engaged in the constant task of “demagogy hunting” (Demagogenjagd), popular heroes like Jahn and Arnold being haled to prison for frivolous charges, and even Gneisenau and Scharnhorst surrounded with spies.

Meanwhile, by an ordinance of the 20th of April 1814 the kingdom had been divided into eight provinces, each province into government districts (Regierungsbezirke) and, these again into “circles” (Landschaften) administered by Landrätte (landraths). At the same time the kanton system was instituted, a government responsible to the Oberpräsident, who was responsible in his turn to the ministry under the chancellor. On the 20th of March 1817 was created a council of administration (Verwaltungsrat) headed by the minister of war and a certain number of members nominated by the king, whose function was to supervise the administration and discuss projects of legislation. Its immediate tasks were to bring the new provinces into the fold of the kingdom and for years the Prussian police engaged in the constant work of separating “demagogy hunters” (Demagogenjäger), popular heroes like Jahn and Arnold being haled to prison for frivolous charges, and even Gneisenau and Scharnhorst surrounded with spies.

The New Provinces.

The Toleration Law.

In educational matters also the government achieved results of lasting value. The university of Bonn was founded, the others were reorganized; numerous Gymnasien were built and above all

Accessions in 1815. After 1815.

elementary education was made universal and compulsory. Less happy was Frederick William’s attempt to adjust the religious differences of his subjects with the corporal’s cane. In 1817, the tercentenary of the Reformation, a royal decree announced that henceforth Lutherans and Calvinists formed to unite in one “Evangelical Church,” the public use of the name “Protestant” being officially forbidden. The so-called Old Lutherans, who refused to conform, were forbidden to found and operate communities, their representatives being dragged and imprisoned. A quarrel also broke out with the Roman Catholic Church on the question of “mixed marriages,” which culminated in 1837 in the imprisonment of Baron Droste zu Vischering (q.v.), archbishop of Cologne, and of the archbishop of Posen.

In foreign politics, too, Prussia played but a secondary rôle after 1815. The king either attended, or was represented at, the various congresses of Europe. Of his own free will and of his sole idea was to support the views of Metternich, and later, those of the emperor Nicholas I. of Russia. (See EUROPE: History.)

Frederick William III. died on the 7th of June 1840. In spite of his faults, he had accomplished great things for Prussia, and his kindness of heart, his devotion to duty and the memory of his sufferings maintained his personal popularity to the last (see Frederick William III., King of Prussia). Of his son, William IV., were expected, since his talents were undeniable 1840-1845, and he had gained as crown prince a reputation for Liberalism. One of his first acts was to liberate Jahn and the imprisoned archbishops, to reinstate Arndt in office and to issue a general amnesty (Aug. 10, 1840). Five years later he allowed the Old Lutherans liberty to set up a Church of their own. But in spite of these promising beginnings, it was soon clear that the king was wholly out of touch with the ideas of modern Liberalism. In spite of the warnings of the emperor Nicholas I. and of Metternich, he sought to satisfy the cry for a constitution by issuing on the 13th of February 1847 a patent summoning the “united Diet” for Prussia—that is to say, a mere “concentration” of the provincial Diets. The story of the contest that followed between the Crown and the people is outlined elsewhere (see Germany). It is only necessary to give here some account of the constitutional development in Prussia itself.

The most important law landmark in this respect was the law promulgated after the dissolution of the lower house of the revolutionary National Assembly on the 27th of April 1849. This law, which was only slightly modified by the electoral reform law of 1910, divided the parliamenary electors into three classes, their voting power being determined by property qualifications or by official and professional position, and refractory pastors who the disgusted democrats took no part, with the result that the chambers that met on the 7th of August 1849 were strongly Conservative and made no difficulty about revising the democratic constitution of 1848 in accordance with the royal wishes. The constitution, thus amended, was proclaimed on the 31st of January 1851, and has remained substantially that of Prussia ever since. Its immediate effect was an extraordinary series of reactionary measures, e.g. the restoration of the old manorial courts and of the provincial estates (1850). The actual constitution of the parliament as consisting of a House of Lords (Herrenhaus) and House of Delegates (Abgeordnetenhaus) was fixed in 1854, and in this assembly the dominant element continued to be that of the Prussian Junkerium or squirearchy, which supported the king and his government in all their reactionary efforts.

Far as the internal history of Prussia is concerned, little was altered by the substitution of William as regent for his brother, now hopelessly mad, in 1858. The new ruler, who became king in 1861, shared to the full his predecessor’s views as to the divine right of the Prussian crown. He was prepared to accept the established constitutional forms, but he was not prepared to sacrifice to them what he firmly believed to be the divinely appointed mission of Prussia in Germany. Bismarck, who became prime minister in 1862, fully shared his master’s views. He realized, what the lower house did not, that the German question could only be settled as the result of a trial of strength between Prussia and Austria and that therefore it was necessary for Prussia to spend money on armaments; and, since he could not give his real reasons to the parliament and the parliament refused to accept the reasons he did give, he raised the necessary funds in defiance of the votes of the House of Delegates. The result justified him in the eyes of the Prussian people. Bismarck’s policy, culminating in the war of 1866, left Prussia the undisputed mistress of Germany (see SCHLESWIG-HOLSTEIN QUESTION; and Germany: History). By the Treaty of Prague (Aug. 23, 1866) Prussia acquired Hanover, Hesse-Cassel, Hesse-Nassau, Frankfort and the duchies of Schleswig-Holstein and Lauenburg; her territory had been increased by one-fifth and became for the first time satisfactorily rounded off and compacted; by the acquisition of the Elbe duchies, too, she laid the foundations of her future sea-power. In 1871 as the result of the German victory over France the king of Prussia became German Emperor.

From 1869 onwards Prussia has had from the point of view of international politics no existence apart from the North German Federation and the German Empire; and even in internal affairs her preponderance and influence in Germany have been overwhelming. For all practical purposes the German Empire has been a Prussian Empire, and, however much the still surviving partialist feeling of the lesser states has restrained the process, the “Prussianisation,” in greater or less degree, of all Germany was inevitable from the moment that the great imperial departments—army, consistorial, posts, railways—were placed under Prussian authority or conformed to the Prussian model. With this particular expansion of Prussia, however, we are not concerned, but solely with the internal development of the Prussian Kingdom itself. The main tasks that lay before the government after 1870 were the assimilation of the new provinces, the reorganization of the administration, the economic development of the country, the settlement of the question of the Church, the rapid colonization of the Roman Catholics on the one hand and the Social Democrats on the other. On the whole the new German princes accepted their fate with equanimity, though in Hanover externally the deposition of the dynasty continued to be a considerable following of which the ablest spokesman was Windthorst (q.v.). Since the dispossessed princes refused to resign their claims, the large sum of money which had been assigned to them by the new parliament was not paid, and the Prussian government instead of the Guelph Fund (Welfenfonds), formed a secret service supply highly convenient for Bismarck’s purposes.

More difficult was the task, rashly undertaken by the government, of establishing the line of Prussian influence in the Baltic provinces of the Polish districts in the eastern provinces, a task which after thirty years of effort shows but very small results (see SCHLESWIG-HOLSTEIN QUESTION, ad fin.; and POSEN).

In the connected question of the Church was the quarrel with the Roman Catholic Church, known as the Kulturkampf, of which Prussia was the focus (see Germany: History, xi. 880 seq.). The anti-Vatican policy, associated throughout with the name of the minister Falk, necessitated an alliance of the government with the Liberals, and this led to a policy of at least administrative reform. The present administrative system (Kreisordnung) of Prussia was introduced in 1867, but the countryside was left untouched until 1888, when it was applied to Posen. The Liberalism of the Prussian parliament was, however, of a very lukewarm temper; and when in 1878-1879 Bismarck decided to strike at the fiscal system and reinforce the repressive legislation against the Social Democrats, the Liberals were not strong enough to offer an effective resistance. In 1879 the moderate Liberal ministry resigned, and the Kulturkampf was the result, in which the most conspicuous figure was Robert von Puttkamer (q.v.). Henceforth the government depended for parliamentary support on a union of the National Liberals and democrats of various shades as the Imperial Opposition.

An eventual understanding with the Holy See was not possible, though the Kulturkampf was not actually settled until 1888, when the Prussian government, assisted by the diplomatic attitude of Pope Leo XIII., came to terms with Rome. The problem in 1879-1888 was Bismarck’s encouragement in state socialism and the struggle caused by the purchase of the state of the three of the great railways, thus laying the foundation of the present system of state railways in Prussia.

On the 9th of March 1888 William I. died. His successor,
PRUSSIA—PRUSSIC ACID

Frederick III., only lived till the 15th of June, the sole important act of his reign being the dismissal of Puttkammer. Under his successor William II. the development of Prussian affairs continued on the lines laid down under William I., change into one between these masses and the government tended to Socialism—denounced by the king-emperor as treasonFranzösischer Reform, among the unrepresented population. Discontent grew apace, and the trouble culminated in 1908 and 1909. In 1906 a bill raising the number of members of the Diet from 433 to 443 and effecting an unimportant redistribution of seats had been passed, but a Radical amendment in favour of direct and universal suffrage and the secret ballot had been rejected by a large majority. In 1907 the elections for the Reichstag resulted in a remarkable defeat of the Social Forces, and this has a lasting effect in Prussia also. In 1908 a resolution in favour of universal suffrage was again brought forward. It was opposed by Prince Bülow, the German chancellor, and was rejected by a large majority. Riots followed in Berlin and demonstrations in favour of reform throughout the country, and at the new elections in June seven Socialist members were returned—a portentous phenomenon under the actual franchise. In the session of 1909 the reform resolution was again brought forward, and again thrown out by the Conservative majority.

Demonstrations and collisions with the police followed in most of the large Prussian towns, and in October four of the Socialist members returned in 1908 who had been unseated on technical grounds were re-elected. It became clear to the government that some sop must be thrown to popular opinion, and accordingly in the speech from the throne delivered on the 11th of January 1910 the king-emperor announced a measure of franchise reform. The agitation, however, continued, and the terms of the bill when it was introduced by Herr von Bethmann-Hollweg on the 10th of February were not such as to conciliate opposition. The chancellor and minister-president adhered to the principles enunciated by his predecessor; the bill retained the triple class division of voters, public voting and plural votes; the voting, however, was to be direct and certain changes were suggested giving less to the moneyed interest and more to the professional classes. A furious agitation at once arose all over the country, culminating in a series of Socialist demonstrations on the 14th in Berlin and elsewhere; owing to the elaborate police precautions there was, however, no serious disturbance; but on the evening of the 18th there was street fighting between rioters and police in Frankfurt. Meanwhile, on the 13th, the bill had been referred to a committee of the Diet. No party was satisfied with it; the Berlin municipality petitioned for its entire rejection; but it was ultimately referred to a special committee consisting of the representatives of the Conservative and Catholic Centre parties on the committee, the latter agreeing to support the retention of indirect voting on condition of the former declaring in favour of the secret ballot (Feb. 22). In this sense the committee ultimately reported, in spite of the government's efforts to retain public voting and to concede direct election, and on the 14th of March the bill in this shape passed its second reading. On the 16th the third reading was carried, all the parties except the Conservatives and the Centre voting against it; Herr von Bethmann-Hollweg accepted the bill on behalf of the government, merely reserving the right to amend it in matters of detail. Demonstrations and riots in various centres showed how far this result was from satisfying the popular demands.

Thus Prussia retained, in contradiction to the South German states, its traditional character, as a land ruled from above, the monarchy and the bureaucracy basing their authority not on the will of the people, but partly on divine right and partly on the middle-class terror of the social revolution, while as its ultimate sanction there remained the tremendous power of the king of Prussia as supreme "war lord" of Germany. It remained to be seen how long these conditions could last in a country which, during the tremendous material expansion of the period following the war, had developed an immense industrial population which saw, or thought it saw, its interests sacrificed to the agricultural classes, with their traditional feudalism and inherited loyalty to the Prussian system.

Zurbonen, Quellenbuch zur brandenburg-preuss. Gesch. (Berlin, 1889), Zeitschr. für preussische Gesch. (i.ii. 1884-1889), Forschungen zur preuss. Gesch. (Leipzig, 1888 sqq.). Records of the Prussian government in the 18th century are being published under the title of Acta borussica (Berlin, 1892 sqq.). Among important general works may be mentioned Ranke, Zwölfter Buch preussischer Gesch., 5 vols. to 1745 (2nd ed., Leipzig, 1835); Dietz, Ergebnisse der preussischen Politik, i. 2 vols. to 1855 (Berlin and Leipzig, 1868); H. G. Prutz, Preussische Geschichte, 4 vols. to 1888 (Stuttgart, 1890-1902); and for constitutional history, C. Bornhak, Preussische Staats- und Reichsgeschichte (Berlin, 1903). Of the many works devoted to special periods Treitschke's Deutsche Geschichte im 19. Jahrhundert (Leipzig, 1879-1894), in spite of its strong Prussian bias, is especially valuable for the period up to 1848, when it breaks off. See also the lists of books attached to the biographies of the various Prussian kings and statesmen.

PRUSSIA, in the original and narrower sense of the word, a territory of Germany, the kingdom of Prussia, stretching along the Baltic coast of Europe and occupying an area of 24,083 sq. m. The eastern part of this territory formed the duchy of Prussia, which was conquered and colonized by the Teutonic Order and was acquired by the elector of Brandenburg in 1618, furnishing his successor with his regal title in 1701. The western part, which had been severed from the eastern half and assigned to Poland in 1466, was not annexed to Prussia until the partition of Poland in 1772, while the towns of Danzig and Thorn remained Polish down to 1793. The two districts were united in 1824 to form a single province. But, as might have been expected, the union did not work well, and it was dissolved in 1878, its place being taken by the modern provinces of East and West Prussia. (See East Prussia and West Prussia.)

PRUSSIC ACID, or Hydrocyanic Acid, HCN, an organic acid first prepared in 1782-1785 by C. Scheele and subsequently examined by J. Gay-Lussac. It is present in varying amounts in certain plants, being a product of the hydrolysis of the cyanogenetic glucosides, e.g., amygdalin (q.v.). It may be prepared by heating a mixture of cyanogen and hydrogen to 500°-550° C. (M. Berthelot, Ann. chim. phys. 1879 (5) 18, 1879) by passing induction sparks through a mixture of acetylene and nitrogen; by the dry distillation of ammonium formate; by the decomposition of the simple cyanides with mineral acids; and by distilling potassium ferrocyanide with dilute sulphuric acid (F. Wöhler, Ann. 1850, 73, p. 210). The anhydro acid being obtained by fractional distillation of the aqueous distillate, special precautions being necessary owing to the excessively poisonous nature of the free acid:

$$\text{KFe(NC)}_6 + 3\text{H}_2\text{SO}_4 = 2\text{K}_2\text{SO}_4 + \text{FeSO}_4 + 6\text{HCN}$$

The free acid is a colourless liquid with a smell resembling bitter almonds; it boils at 26-8° C., and may be solidified, in which condition it melts at -4° C. It burns with a blue flame, and is readily soluble in water, but the solution is unstable and decomposes on standing, giving amorphous insoluble substances, and ammonium formate, oxalic acid, &c. An aqueous solution of hydrogen peroxide converts it into oxamide, (CONH)_2, and reduction by zinc and hydrochloric acid gives methylamine. The anhydro acid combines with hydrochloric, hydrobromic and hydroiodic acids to form crystalline addition products, which
PRUSSIC ACID

529

decomposed by water with the formation of the corresponding ammonium salt and formic acid. It combines with alkaline solutions to give carbonate and charcoal, and with water it yields oxalic acid.

Cyanides.—The salts of this acid, known as cyanides, may be prepared by the action of cyanogen or of gaseous hydrocyanic acid or by heating the cyanides of the alkaline metals in a current of hydrocyanic acid; by heating alkaline carbonates with carbon in the presence of free nitrogen: \( \text{BaCO}_3 + 4 \text{C} + 3 \text{N}_2 = \text{Ba(NC)}_3 + 3 \text{CO} \); by ignition of nitrogenous organic substances in the presence of alkaline carbonates or hydroxides; or by processes of double decomposition. The alkali and alkaline earth cyanides are soluble in water and in alcohol, and their aqueous solution, owing to hydrolytic dissociation, possesses an alkaline character. When heated in contact with air they undergo a certain amount of oxidation, being converted to some extent into the corresponding cyanate. The cyanides of other metals are decomposed by heat, frequently with liberation of cyanogen. The cyanides, when pure, are red or brown; those which are not are mostly insoluble in water, and are soluble in a solution of potassium cyanide, forming more or less stable double salts, for example \( \text{KAg(NC)}_3 \), \( \text{KAu(NC)}_3 \). Lead cyanide, \( \text{Pb(NC)}_3 \), however, does not form such a salt, and is insoluble in potassium cyanide solution.

Ammonium cyanide, \( \text{NH}_4 \text{NC} \), a white solid found to some slight extent in illuminating gas, is easily soluble in water and alcohol, and is very poisonous. Its vapour is inflammable. It is obtained by passing nitrogen over hot burning amalgam of ammonium chloride and potassium cyanide; by passing a mixture of ammonia gas and chloroform vapour through a red hot tube; and by heating a mixture of ammonia and carbon monoxide: \( \text{CO} + \text{NH}_2 + \text{H}_2 = \text{CO}_2 + \text{NH}_3 \). From the alkaline cyanates, prepared by the action of potassium cyanate on baryta, or by passing nitrogen over a heated mixture of barium carbonate and coal, is a white solid, which when heated with water to 300° C. loses the whole of its nitrogen in the form of ammonia. The Metallurgische Cyanide, \( \text{Hg(NC)}_2 \), is a sparingly soluble salt formed by dissolving prussic acid in hydrocyanic acid, or by boiling potassium ferrocyanide with mercuric sulphate and water: \( 2\text{KFe(NC)}_3 + 3\text{HgSO}_4 + 3\text{HNC} + 3\text{KSO}_4 + 2\text{KFe(NC)}_3 \). Its aqueous solution is not an electrolyte, and consequently does not give the reactions of the mercury and cyanogen ions. When heated it yields mercury, cyanogen and para-cyanogen.

Silver cyanide, \( \text{Ag(NC)}_2 \), is formed as a white precipitate by adding potassium cyanide to silver nitrate solution; or better, by adding potassium cyanate to silver nitrate solution and heating. In this manner double cyanide is obtained by the addition of one molecular proportion of potassium cyanide to one molecular proportion of silver nitrate, the white precipitate so formed being then dissolved by the addition of hydrocyanic acid, when it is converted into the dissolved cyanide. Double cyanide is also obtained by dissolving potassium cyanate in an alkaline solution of potassium carbonate and heating, and by the following equation: \( \text{C}_2\text{S}_2 = 2\text{HNC} + 2\text{Ca(OH)}_2 = \text{Ca(CN)}_2 + \text{Ca(SH)}_2 + 2\text{HO} \). The product is then treated with a current of carbon dioxide, calcium carbonate being precipitated, sulphuric acid being formed, and calcium sulphocyanate remaining in solution. The sulphocyanate is converted into the potassium salt by adding potassium sulphate, and finally desulphurized by lead, zinc, or iron.

Potassium cyanide is an excessively poisonous, colourless, deliquescent solid; it is freely soluble in water, but almost insoluble in absolute alcohol. It is stable in dry air, but is easily oxidized when fused, in which condition it is a powerful reducing agent. It dissolves gold (qu.) in the presence of water and atmospheric oxygen.

It is also largely used by the jeweler, electroplater and photographer.

Double Cyanides.—The double cyanides formed by the solution of the cyanide of a heavy metal in a solution of potassium cyanide are decomposed by mineral acids with liberation of hydrocyanic acid and formation of the cyanide of the heavy metal. Besides these, other double cyanides are known which do not suffer such decomposition, the heavy metal present being combined with the cyanogen radical in the form of a complexion. The most important members of these classes are the ferro- and ferri-cyanides and the nitroprussides.

Potassium ferrocyanide, \( \text{K}_4\text{Fe(NC)}_6 \), (yellow prussiate of potash) was first obtained by decomposing Prussian blue with oxygen: \( \text{Fe(NC)}_3 + 2\text{KOH} = \text{K}_4\text{Fe(NC)}_6 + 2\text{Fe} \); it may also be obtained by warming a solution of ferrous sulphate with an excess of potassium cyanide: \( \text{FeSO}_4 + 6\text{KNC} = \text{K}_4\text{Fe(NC)}_6 + \text{K}_2\text{SO}_4 \). The older processes for the commercial preparation of this salt, which were based on the ignition of nitrogenous substances with an alkaline carbonate and carbon, have almost all been abandoned, since it is more profitable to prepare the salt from the by-products obtained in the manufacture of illuminating gas. W. Forsyth Hasslacher of Philadelphia (1883) prepared potassium ferrocyanide (ammonia) through a solution of potassium carbonate containing ferric oxide or ferric carbonate (actually ferrous sulphate and potassium carbonate) in suspension; the sulphocyanate hydrogen in the presence of hydrogen peroxide, and the peroxide replacing the ferric oxide; and, then, in the presence of the hydrocyanic acid in the gas, and the alkaline carbonate, forms the ferrocyanide, thus: \( \text{Fe} + 6\text{HNC} + 2\text{KCO}_3 = \text{K}_4\text{Fe(NC)}_6 + \text{H}_2\text{S} + 2\text{CO}_2 + 2\text{H}_2 \). The salt is re-converted to the ferrocyanide by passing the gas through the solution in the presence of potassium cyanate. The process is not efficient, since the solutions are too dilute and large quantities of liquid have to be handled. A large quantity of the salt is now prepared from the “spent oxide” of the gas works, the cyanogen compounds formed in the combustion of the gas containing with the ferric oxide in the purifiers to form insoluble iron ferrocyanides. The soluble salts are removed by lixiviation, and the residue is boiled with lime to form the soluble calcium ferrocyanide, which is finally converted into the potassium ferrocyanide.

The salt crystallizes in large yellow plates, containing three molecules of water of crystallization. It is soluble in water, but insoluble in alcohol. It is not poisonous. When fused with potassium cyanate it forms potassium ferrocyanide (below), and when treated with dilute sulphuric acid it yields hydrocyanic acid, but with concentrated sulphuric acid it yields carbon monoxide: \( 6\text{H}_2\text{O} + 2\text{KFe(NC)}_6 + 6\text{H}_2\text{SO}_4 = 2\text{K}_2\text{SO}_4 + \text{Fe}_2\text{O}_3 + 3\text{NH}_4\text{SO}_4 + 6\text{OC} \). Oxalic acid is formed when potassium ferrocyanide is warmed with potassium carbonic acid.

Potassium ferrocyanide may be estimated quantitatively in acid solution by oxidation with ferric oxide by passing hydrogen peroxide (or other reducing agents): \( 5\text{KFe(NC)}_3 + \text{KMnO}_4 + 4\text{H}_2\text{SO}_4 = 5\text{K}_2\text{Fe(NC)}_3 + 3\text{K}_2\text{SO}_4 + \text{MnSO}_4 + 4\text{HO} \).

Hydroferrocyanic acid, \( \text{H}_2\text{Fe(NC)}_3 \), is best obtained by decomposition of the potassium ferrocyanide with hydrochloric acid gas, passing the mixture through a concentrated solution of the potassium salt. In the latter case the precipitate is dissolved in water, precipitated by ether, and washed with ether-alcohol.
It is a tetrasubstituted acid, of markedly acid character, and readily decomposes carbonates and acetates. It dissolves unchanged in concentrated sulphuric acid, and oxidizes readily in moist air, forming Prussian blue (Prussian blue, K₄[Fe(III)Fe(II)]₃, or Fe₂[Fe(II)Fe(II)]₃, ferric ferrocyanide, was discovered in 1710 by a German manufacturer named Diesbach, who obtained it by the action of fused alkali and iron salts on nitrogenous organic matter (e.g. blood). It is now prepared from the calcium ferrocyanide, with which it is identical, by decomposition with a solution of ferric chloride, and then oxidised by a warm solution of ferric chloride: 

\[ 6K_2FeF_6(CN) \rightarrow 3Fe_2(CN)_6^3-+3K_2FeF_6+Fe_2O_3 + FeO \]

It is a dark blue powder with a marked coppery lustre. It is insoluble in water and is not decomposed by heat.

Soluble Prussian blue, K₄[Fe(III)Fe(II)]₃, potassium ferric ferrocyanide, is formed when a solution of potassium ferricyanide is added to an insufficient amount of a ferric salt (1), or when potassium ferrocyanide is added to a ferric salt (2):

1. \[ 2K_2FeF_6(CN)_6 + 2FeCl_3 + 6KCl \rightarrow 2K_2FeF_6(CN)_6 + 2FeCl_3 + 2KCl \]
2. \[ 2K_2FeF_6(CN)_6 + 2Fe(CN)Cl_3 \rightarrow 2K_2FeF_6(CN)_6 + 2Fe(CN)_3Cl \]

It is soluble in water, but is insoluble in cold solutions.

Potassium ferrocyanide, K₃[Fe(II)Fe(II)]₃, red precipitate of potash, is obtained by oxidising potassium ferrocyanide with chloride, bromine, &c., and the mixture with a solution of potassium ferrocyanide is added to a solution of potassium ferrocyanide to a solution of zinc sulphate and manganese dioxide, through the mixture: \[ 2K_2FeF_6(CN)_6 + CaCl_2 + CO_2 \rightarrow 2K_2FeF_6(CN)_6 + CaCO_3 + 2KCl \]

The mixture of calcium and lead carbonates is filtered off and washed at a low red heat to remove the lead carbonate. It crystallizes in monoclinic prisms which are readily soluble in water. The solution decomposes on standing, and the mixture in an alkali acts as an oxidising agent: \[ 2K_2FeF_6(CN)_6 + 2KOH \rightarrow 2K_2FeF_6(CN)_6 + KOH + H_2O \]

With a pure water it gives a brown colour. It can be estimated qualitatively by mixing a dilute solution with potassium iodide and hydrochloric acid in excess, and adding excess of sodium thiosulphate. It crystallizes in monoclinic prisms which are readily soluble in water. It is decomposed on boiling with a solution of sodium bicarbonate, and determining the amount of free acid by a standard solution of potassium thiosulphate. The zinc sulphate is added in order to remove the ferrocyanide formed as an insoluble zinc salt: \[ 2K_2FeF_6(CN)_6 + 2HCl + 2KCl \rightarrow 2K_2FeF_6(CN)_6 + H_2O + 2KCl \]

An alternative method it may be decomposed by hydrogen peroxide in alkaline solution and the amount of evolved oxygen measured:

\[ 2K_2FeF_6(CN)_6 + 2KOH + H_2O \rightarrow 2K_2FeF_6(CN)_6 + 2H_2O + O_2 \]

The potassium hydroferrocyanic acid, K₃[Fe(II)Fe(II)]₃, is best obtained by adding a hot solution of potassium ferrocyanide to a ferric salt, and allowing the mixture to stand some time in the presence of an iron salt: \[ 2K_2FeF_6(CN)_6 + 3FeSO_4 + 3FeF_6(CN)_6 \rightarrow 3K_2FeF_6(CN)_6 + 3FeSO_4 \]

Hydroferrocyanic acid, H₂FeF₆(CN), obtained by adding concentrated hydrochloric acid to a cold saturated solution of potassium ferrocyanide, crystallizes in brown needles, and is easily decomposed.

Nitroprusside.—The nitroprussides are salts of the type M₄Fe(CN)₆NO. The free acid forms dark red deliquescent crystals and is obtained by decomposing the sliver salt with hydrochloric acid, or the barium salt with dilute sulphuric acid.

Sodium nitroprusside, Na₂Fe(CN)₆NO₂H₂O, is the commonest salt of this type. It is prepared by oxidising with dilute nitric acid, by a solution of potassium ferricyanide with a dilute nitric acid. The solution is evaporated, separated from potassium nitrite, the free acid neutralized with soda, and the solution concentrated. It crystallizes in dark red prisms which are readily soluble in water: it is a valuable reagent for the detection of sulphur, this element when in the form of an alkali sulphide giving a characteristic purple blue colouration with the nitroprusside. The potassium salt may be prepared by adding potassium cyanide to ferrous acetate solution and allowing the brown precipitate so formed when being then heated with potassium nitrite:

\[ 5KNC + 2FeSO_3 = 2K_2SO_4 + KFe(CN)_6 \]
\[ 2KFe(CN)_6 + 2KNO_3 = Fe_2O_3 + K_2Fe(CN)_6 + NO \]

Other complex cyanides are known which may be regarded as derived from the acids H₂X(CN)₃, X = Na, Li, Pt, Pt; H₂X(CN)₄, X = Fe, K; H₂X(CN)₅, X = Co, Rb, and R (R = any alkali, Na, K, etc.). (Anorg. Chem., 1859.)

Organic Cyanides or Nitriles.—Hydrocyanic acid forms two series of derivatives by the exchange of its hydrogen atom for alkyl or aryl groups; namely the nitriles, of type R-CN, and the isonitriles, of type R-NC. The latter compounds may be considered as derivatives of the as yet unknown isohydrosicyanic acid NC₃.

Nitriles.—These substances were first isolated in 1834 by J. Pélouze (Ann. Chim., 1834, 10, p. 249). They may be prepared by heating the alkyl iodides with potassium cyanide; by heating sulphuric acid esters with potassium cyanide; by distilling the acid-amides with sodium cyanide; and by distilling amides (containing more than five atoms of carbon) with bromine and potash (A. W. Hofmann), for example:

\[ CH₃CH₂NH₂ + CH₃CH₂CN → CH₃CH₂NH + CH₃CH₂CN \]

In addition to these methods, the nitriles of the aromatic series may be prepared by distilling the aromatic acids with potassium cyanide, or by extracting the potassium cyanides with benzene (C. K. Kahlbaum). The subsequent action of distilled water on the benzene solution gives the nitrile:

\[ C₆H₅COH + HCN = CH₃CN + H₂S + CO₂ \]

Nitriles derived from benzaldehyde with potassium cyanide give hydrogen cyanide and nitriles (C₆H₅CN + CH₃CN → C₆H₅CN + CH₃CN + H₂S + CO₂).

The action of potassium cyanide on nitriles with a hydrocarbon radical gives hydrogen cyanide and nitriles (C₆H₅CN + CH₃CN → C₆H₅CN + CH₃CN + H₂S + CO₂).

These nitriles are generalised with the nitriles, since they form soluble double silver salts, and the fact that ethyl ferrocyanide on distillation yields ethyl isocyanide also points to their isocyanide structure. J. Wade (loc. cit.) explains...
The formation of nitriles from potassium cyanide, and of isonitriles from silver cyanide by the assumption that unstable addition products are formed, the nature of which depends on the relative state of unsaturation of the carbon and nitrogen atoms under the varying conditions.

\[ \text{KNC} \rightarrow \text{KN C(HCN)} \rightarrow \text{KC(CN)} \]

AgNC \(\rightarrow\) AgNC(HCN) \(\rightarrow\) AgCNHCN.

That is, when the metal is highly electro-positive the carbon atom is the more unsaturated, the addition takes place on the carbon atom, and nitriles are produced. The same type of reaction occurs when the metal is not highly electropositive or the radical, for example, with ethyl isocyanide and acetyl chloride (see above). Compare also AgNC \(\rightarrow\) AgNC(Cl-COCH\(_3\)) \(\rightarrow\) AgCl+CH\(_2\)COCN.

On the other hand, when there is but little electro-chemical difference between the two atoms, the cyanide and that of the reacting compound then the nitrogen atom takes the element of the nitriles. The nitriles are produced. This explanation also accounts for the formation of nitriles by the diazo reaction, thus:

\[ \text{C}_3\text{H}_6\text{NCl}+\text{CN} \rightarrow \text{C}_3\text{H}_6\text{N-Cl}+\text{C}_3\text{H}_6\text{N-N}\text{C}_3\text{H}_6\]

Detection. The metallic cyanides may be detected by adding ferrous sulphate, ferric chloride, and hydrochloric acid to their solution, when a precipitate of Prussian blue is produced; if the original solution contains free acid it must be neutralised by caustic potash before the reagents are added. As an alternative test, the cyanide may be decomposed by dilute hydrochloric acid, and the liberated hydrocyanic acid absorbed in a little yellow ammonium sulphide. The excess of reagent is removed by evaporation and a small quantity of water and a little red colour is produced. Silver nitrate gives a white precipitate with cyanides, soluble in excess of potassium cyanide. The amount of hydrocyanic acid in a solution may be determined by adding excess of caustic potash, obtaining the precipitate of sodium cyanide and titrating into the dilute solution standard silver nitrate until a faint permanent turbidity (of silver chloride) is produced, that is, until the reaction:

\[ 2 \text{KNC}+\text{AgNO}_3 \rightarrow \text{KAg}(\text{NC})+\text{KNO}_3 \]

is complete.

Pharmacology, Therapeutics and Toxicology of Hydrocyanic Acid.

The pharmacopoeial preparations of this acid are a 2% solution, which is given in doses of from two to six minims, the \textit{infusoria chloroformi et morphinae composita}, which contains a half-minim of this solution in each ten minims, and the \textit{aqua laurocerasi}, which owes its virtues to the presence of this acid, and is of inconstant strength, besides being superfluous. The acid is also the active ingredient of the preparations of Virginian Prune, to which the same strictures apply.

The simple cyanides share the properties of the acid, except those of platinum and iron. With these exceptions, the simple cyanides are readily decomposed even by carbonic acid, free prussic acid being formed. Phosphorus pentacynide is a protopathic poison, directly lethal to all living tissues, whether in a plant or an animal. It is by no means the most powerful poison known, for such an alkaloid as pseud-acetonyne, which is lethal in a dose of about 1/100 of a grain, is a hundred times more toxic, but prussic acid is by far the most rapid poison known, a single inhalation of it producing absolutely instantaneous death. The acid is capable of passing through the unbroken skin, whereupon it instantly paralyses the sensory nerves. It is rapidly absorbed from raw surfaces and may thereby cause fatal consequences. It is naturally an antisepsic.

The therapeutic applications of the drug are based entirely upon its action on the heart, and its power of producing ten times the power of the dilute acid to an ounce of water and glycerin will relieve itching due to any cause; and is useful in some forms of neuralgia. It must never be employed when the skin is abraded. The diluted acid is useful for all purposes requiring gasification. It is also added to cough mixtures, when the cough is of the dry, painful kind, which serves no purpose, as nothing is expectorated. Such a cough is relieved by the sedative action on the central nervous system.

The dilute acid is poisonous to man, from 0.001 to 0.002 per cent. of the pure acid. The diluted form, in toxic quantities, will cause symptoms usually within a few seconds. The patient is quite unconscious, the eyes are motionless, the pupils dilated, the skin cold and moist, the breath rancid, the face livid, the lips blue, the respiration very slow and convulsive. Post mortem, the body is livid, and the blood very dark. There may be an odour of prussic acid, but this soon disappears.

The drug is rapidly of use, owing to the rapidity of the toxic action. The patient who survives half-an-hour will probably recover, as the volatile acid is rapidly excreted by the lungs. The drug kills by paralysing the nervous arrangements of the heart and respiration. The appropriate drug is therefore atropine, which stimulates the respiration and prevents the paralysis of the heart.

One-fiftieth of a grain must be immediately injected subcutaneously. The stomach must be washed out and large doses of emetics given as soon as possible. Every second is of consequence. Ammonia should be given by inhalation, and artificial respiration must never be forgotten, as by it the paralyzed breathing may be compensated for and the poison excreted. The use of chemical antidotes, such as iron salts, is futile, as the drug has escaped into the blood from the stomach long before they can be administered.

**PRUTZ, HANS** (1843– ), German historian, son of Robert Eduard Prutz (1816–1872), the essayist and historian; was born at Jena on the 20th of May 1843, and was educated at the universities of Jena and Berlin. In 1865 appeared his monograph on Henry the Lion, duke of Saxony and Bavaria, which was followed by three volumes on the emperor Frederick Barbarossa (Kaiser Friedrich I., Danzig, 1871–1874). Meanwhile from 1863 to 1873 he was teaching in secondary schools. In 1874 he rejoined the government and served again in Syria, particularly at Tyre, and as a result he published in 1876 \textit{Aus Phönizien}, a collection of historical and geographical sketches. In the same year appeared his first work on the Crusades, \textit{Quellenbeiträge zur Geschichte der Kreuzzüge}, and a series of monographs on the same subject culminated in 1883 in the notable \textit{Kulturgeschichte der Kreuzzüge}. Then turning to a wider theme Prutz contributed to Oncken's history the two volumes on the political history of Europe during the middle ages (Staatengeschichte des Abendlandes im Mittelalter, Berlin, 1885–1887). In 1888 he reverted to a subject which he had touched upon in his Geheimlehre und Geheimstatuten des Tempelherrenordens (Danzig, 1879), and wrote the history of the rise and fall of the Templars (\textit{Entwicklung und Untergang des Tempelherrenordens}), which is noticed in the article Templars. His Preussische Geschichte (4 vols., Stuttgart, 1899–1902), which is perhaps his most notable work, is a long and serious attempt to justify the Prussian rather than patriotic character of a subject which has been mainly in the hands of historians with a patriotic bias. He also wrote \textit{Aus des Grossen Kurfürsten letzten Jahren} (Berlin, 1897) and \textit{Bismarcks Bildung, ihre Quellen und ihre Äusserungen} (Berlin, 1904). In 1902 Prutz resigned the chair of history in the university of Königsberg, which he had held since 1877, and took up his residence at Munich.

**PRUTZ, ROBERT EDUARD** (1856–1872), German poet and prose writer, was born at Stettin on the 30th of May 1856. He studied philology, philosophy and history at Berlin, Breslau and Halle, and in the last named became associated, after taking his degree, with Arnold Ruge in the publication of the \textit{Halleische Jahrbücher}. Subjected on account of his advanced political views to police surveillance, he removed to Jena, where, on the strength of an excellent monograph, \textit{Der Göttin Phöbus} (1841), he hoped to obtain an academic appointment. He was, however, expelled from the town for offending the press laws, and it was not until 1846 that he received permission to lecture in Berlin. From 1849 to 1859 he was extraordinary professor of literature at Halle, but retired in 1859 to Stettin, where he died on the 21st of June 1872.

Prutz belonged to the group of political poets who dominated German literature between 1841 and 1848; his poems are more conspicuous for their liberal tendency than their poetry. Among them may be mentioned \textit{Ein Märchen} (1841); \textit{Gedichte} (1841); \textit{Aus der Heimat} (1858); \textit{Neue Gedichte} (1866); \textit{Herbststrosen} (1865); \textit{Buch der Liebe} (1860). Among his novels are noteworthy, \textit{Das Engelskind} (1851) and \textit{Der Musikanenturn} (1855). Much more important are his contributions to literary history and criticism. \textit{Vorlesungen über die Geschichte des deutschen Theaters} (1847); \textit{Ludwig Holberg} (1857); \textit{Die deutsche Literatur der Gegenwart} (1859), and \textit{Menschen und Bücher} (1862). Prutz also wrote some monographs on various literary subjects.

**PRYNNE, WILLIAM** (1600–1669), English parliamentarian, son of Thomas Prynne by Marie Sherston, was born at Swinside near Bath in 1600. He was educated at Bath Grammar School, matriculated at Oriel College, Oxford, in 1618, obtained his B.A. in 1621, was admitted a student of Lincoln's Inn the same year, and was called to the Bar in 1628. He was Puritan
to the core, with a tenacious memory, a strength of will bordering upon obstinacy, and a want of sympathy with human nature. His first book, The Persecution of a Regenerate Man’s Estate (1624), defended one of the main Calvinistic positions, and The Unloneliness of Love-locks and Health’s Sickness (1628) attacked prevailing fashions without any sense of proportion, treating follies on the same footing as scandalous vices.

In 1629 Prynne came forward as the assailant of Arminianism in doctrine and of ceremonialism in practice, and thus drew down upon himself the anger of Laud. Histrio-mastix, published in 1633, was a violent attack upon stage plays in general, in which the author pointed out that kings and emperors who had favoured the drama had been carried off by violent deaths, which assertion might easily be interpreted as a warning to the king, and applied a disgraceful epithet to actresses, which, as Henrietta Maria was taking part in the rehearsal of a ballet, was supposed to apply to the queen. After a year’s imprisonment in the Tower Prynne was sent by the star chamber on the 17th of February 1634 to be imprisoned for life, and also to be fined £5000, expelled from Lincoln’s Inn, rendered incapable of returning to his profession, degraded from his degree in the university of Oxford, and set in the pillory, where he was clothed with a hood and a coat, and the letters S.L., meaning “seditious libeller,” which Prynne, however, interpreted as “stigmata laudis.” He was removed to Carnarvon Castle, and thence to Mont Orgueil Castle in Jersey, where he occupied himself in writing against popery.

Immediately upon the meeting of the Long Parliament in 1640 Prynne was liberate. On the 28th of November he entered London in triumph, and on the 2nd of March 1641, reparation was voted by the Commons, at the expense of his person, to the Bishop of London from the Presbyterians and Catholics and defended the taking up of arms by the parliament. The words “Touch not—mine anointed,” he declared in the Vindication of Psalm cv. ver. 15 (1642), only commanded kings not to oppress their subjects. In 1643 he took an active part in the proceedings against Nathaniel Fiennes for the surrender of Bristol, and showed a vindictive energy in the prosecution of Archbishop Laud. He manipulated the evidence against him, and having been entrusted with the search of Laud’s papers, he published a garbled edition of the archbishop’s private “Diary,” entitled A Breviate of the Life of Archbishop Laud. He also published Hidden Works of Darkness brought to Light in order to prejudice the archbishop’s case, and after his execution, Canterbury’s Doom. . . . an unfinished account of the trial commissioned by the House of Commons. Prynne supported a national church controlled by the state, and issued a series of tracts against independency, including in his attacks Henry Burton his former fellow sufferer in the pillory, John Lilburne and John Goodwin [e.g. Independence Examined (1644)] in Em and Animadversions on Mr. John Goodwin’s Toinmachia (1644), &c. He denounced Milton’s Divorce at Pleasure, was answered in the Colasterion, and contemptuously referred to in the sonnet “On the Forscers of Conscience.” He also opposed violently the Presbyterian system, and denied the right of any Church to excommunicate except by leave of the state [e.g. Four Short Questions (1645); A Vindication of Four Serious Questions (1645)]. He was throughout an enemy of individual freedom in religion.

Prynne took the side of the parliament against the army in 1647, supported the cause of the eleven impeached members, and visited the university of Oxford as one of the parliamentary commissioners. On the 7th of November 1648 Prynne was returned as member for Newport in Charles, he at once took part against those who called for the execution of, and on the 6th of December delivered a speech of enormous length in favour of conciliating the king. The result was his inclusion in “Pride’s Purge” on the morning of the 6th, when, having resisted to military violence, he was imprisoned. After recovering his liberty Prynne retired to Swainswick. On the 7th of June 1649 he was assessed to the monthly contribution laid on the country by parliament. He not only refused to pay, but published A Legal Vindication of the Liberties of England, arguing that no tax could be raised without the consent of the two houses. In the same year he began a long account of ancient parliaments, intended to reflect on the one in existence, and in June 1650 he was imprisoned in Dunster Castle, afterwards at Taunton, and in June 1651 at Pendennis Castle. He was at last offered his discharge on giving a bond of £1000 to do nothing to the prejudice of the commonwealth. This he refused, and an unconditional order for his release was given on the 18th of February 1653. After his release Prynne further expressed his feelings in defence of advowsons and patrons, an attack on the Quakers (1654), and the Restoration in the parliament and of the Jews to England (A Short Demurrer to the Jews) issued in 1656.

On the occasion of the offer of the crown to Cromwell he issued King Richard the Third Revised (1657), and on the creation of the new House of Lords A Plea for the Lords (1658).

On the restoration of the Rump Parliament by the army of the 7th of May 1659 fourteen of the seceded members, with Prynne among them, claimed admittance. The claim was refused, but on the 9th, through the inadventures of the door-keepers, Prynne, Annesly and Hungerford succeeded in taking their seats. When they were observed the house purposely adjourned for dinner. In the afternoon the doors were found guarded; the seceded members were not permitted to pass, and a vote was at once taken that they should not again be allowed to enter the house. Wrathful at the failure of his protest and at the continuance of the republican government, Prynne attacked his adversaries fiercely in print. In England’s Confusion, published on the 30th of May 1659, in the True and Full Narrative, and in Some Pieces of Westminsterassociation he has long accounts of the attempt to enter the house and of his ejection, while in the Cartaene Drownay he held up the claims of the Rump to derision. In Shuffling, Cutting and Dealing, 26th of May, he rejoiced at the quarrels which he saw arising, for “if you all complain I hope I shall win at last.” Concordia discors pointed out the absurdity of the constant tendency to multiply oaths, while “remonstrances,” “narratives,” “queries,” “prescriptions,” “vindications,” “declarations” and “statements” were scattered broadcast. Upon the cry of the “good old cause” he is especially sarcastic and severe in The True Good Old Cause Rightly Stated and other pamphlets. Loyalty Banished explains itself. His activity and fearlessness in attacking those in power during this eventful year were remarkable, and an ironical petition was circulated in Westminster Hall and the London streets complaining of his indefatigable scribbling. On the 27th of December Prynne made another fruitless attempt to take his seat. In obedience to the popular voice, however, on the 21st of February 1660, the ejected members of 1648, led in triumph by Prynne, wearing a basket-hilt sword, re-entered the house. He sat in the Convention Parliament, which met on the 25th of April 1660, and in which he sat for Bath, he urged severe measures against the regicides, and the exclusion of several individuals from the Act of Indemnity. He was foremost in support of the claims of the Presbyterians and against the bishops; advocated the indiscriminate infliction of penalties, and demanded that the officials of the commonwealth should be compelled to refund their salaries. He was nominated a commissioner for disbanding the army, and was appointed keeper of the records in the Tower, a post in which he performed useful services.

Prynne was again returned as member for Bath on the 8th of
May 1661, in spite of the vehement efforts of the Royalists headed by Sir T. Bridge. This parliament was bent upon the humiliation of the Presbyterians, and Prynne appears in his familiar character of protestor. On the 18th of this month he moved that the Engagement, with the Solemn League and Covenant, should be burned by the hangman. About the same time he published a pamphlet advocating the reform of the Prayer Book, while a tract issued on the 15th of July, Sundry reasons against the new intended Bill for governing and reforming Corporations, was declared illegal, false, scandalous and seditious; Prynne being censured, and only escaping punishment by submission. The continued attacks upon the Presbyterians led him to publish his Short, Sober, Pacific Examination of Exuberances in the Common Prayer, as well as the Apology for Tender Consciences touching Not Bowing at the Name of Jesus. In 1662 there appeared also the Briefe Parliamentarie Redevise, possibly a portion of the Brief Register of Parliamentary Writs, of which the fourth and concluding volume was published in 1664. During 1663 he served constantly on committees, and was chairman of the committee of supply in July, and again in April 1664.

In the third session Prynne was once more, on the 13th of May 1664, censured for altering the draft of a bill relating to public-houses after commitment, but the house again, upon his submission remitted the offence, and he again appears on the committee of privileges in November and afterwards. In 1665 and 1666 he published the second and first volumes respectively of the Exact Chronological Vindication and Historical Demonstration of the supreme ecclesiastical jurisdiction exercised by the English kings from the original planting of Christianity to the death of Richard I. In the latter year especially he was very busy with his pen against the Jesuits. In January 1667 he was appointed to manage the evidence at the hearing of the impeachment of Lord Mordaunt, and in November of the same year spoke in defence of Clarendon, so far as the sale of Dunkirk was concerned, and opposed his banishment, and this appears to have been the last time that he addressed the house. In 1668 was published his Auran regiae or Records concerning Queen-gold, the Brief Animadversions on Coke’s Institutes in 1669, and the History of King John, Henry III. and Edward I., in which the power of the Crown over ecclesiastics was maintained, in 1670.

The date of the Abridgment of the Records of the Tower of London, published 1680, is doubtful, though the preface is dated 1656-1657. Prynne died unmarried, in his lodgings at Lincoln’s Inn, on the 24th of October 1669, and was buried in the walk under the chapel there. He left one portion of his books to Lincoln’s Inn, another to Oriel College. His widow bore about 30 sons and daughters, and together, with the replies which they excited, twenty-four columns in the catalogue of the British Museum. Lists of them are given in Wood’s Athenae Oxonienses (ed. P. Bliss), vol. iii., and in Documents relating to the Proceedings against William Prynne.

PRYOR, ROGER ATKINSON (1829— ), American jurist and politician, was born near Petersburg, Virginia, on the 19th of July 1829. He graduated at Hampden-Sidney College in 1844, and at the law school of the University of Virginia in 1848 and in 1849 was admitted to the bar, but devoted himself for some years to journalism. He served as a Democrat in the National House of Representatives from December 1859 to March 1861, and was re-elected for the succeeding term, but owing to the secession of Virginia did not take his seat. He served in the provisional Confederate congress (1861) and also in the first regular congress (1862) of the Confederate constitution. He entered the Confederate army as a colonel, became a brigadier-general (April 16, 1862), and took part in the battles of Williamsburg, Seven Pines, second Bull Run and Antietam. Owing to a

agreement with President Davis he resigned his commission in 1862, but entered General Fitzhugh Lee’s cavalry as a private in August of that year. He was taken prisoner on the 28th of November 1864, but was released on parole by order of the president. In 1865 he removed to New York City, where he practised law. He was judge of the New York court of common pleas in 1869-1894, and of the New York supreme court in 1894-1899. His wife, Sara Agnes (Rice) Pryor (b. 1830), published The Mother of Washington and her Times (1903), Reminiscences of Peace and War (1904), The Birth of the Nation (1907), and My Day: Reminiscences of a Long Life (1909).

PRYTANEUM and PRYTNAS (Gr. root ποιοι, first or chief). 1. In general in ancient Greece, each state, city or village possessed its own central hearth and sacred fire, representing the unity and vitality of the community. The fire (cf. at Rome the fire in the temple of Vesta) was kept alight continuously, tended by the king or members of his family (cf. at Rome the vestal virgins, originally perhaps the daughters of the king). The building in which this fire was kept was the Prytaneum, and the chief (the king or prytyan) probably made it his residence. The word Prytanes (plur. Prytanas) is generally applied specially to those who, after the abolition of absolute monarchy, held the chief office in the state. Rulers of this name are found at Rhodes as late as the 1st century B.C. The Prytaneum was regarded as the religious and political centre of the community and was thus the nucleus of all government, and the official "home" of the whole people. When members of the state went forth to found a new colony they took with them a brand from the Prytaneum altar to kindle the new fire in the colony; the fatherless daughters of Aristides, who were regarded as children of the state at Athens, were married from the Prytaneum as from their home; Thucydides informs us (ii. 13) that in the Synoecism of Theseus (see Athens) the Prytanes of all the separate communities were joined in the central Prytaneum of Athens as a symbol of the union; foreign ambassadors and citizens who had deserved especially well of the state were entertained in the Prytaneum as public guests. In Achaea, this central hall was called the Leptón (town-hall), and a similar building is known to have existed at Elis. This site of the Prytaneum at Athens cannot be definitely fixed; it is generally supposed that in the course of time several buildings bore the name. The Prytaneum, mentioned by Pausanias, and probably the original centre of the ancient city, was situated somewhere east of the northern cliff of the Acropolis. Hence the frequent confusion with the Tholos which was near the council chamber and was the residence of the Prytanes (see above) of the council. Curtius places the original Prytaneum south of the Acropolis in the Old Agora, speaks of a second identical with the Tholos in the Ceramicus, and regrets that of Pausanias as a building of Roman times (Stadtschichte, p. 302). Wachsmuth holds the former view and regards the Tholos as merely a dining-room for the Prytaneis in the old democratic period. Many authorities hold that the original Prytaneum of the Cecropian city must have been on the Acropolis. From Aristotle’s Constitution of Athens (ch. 3) we know that the Prytaneum was the official residence of the Archons, but, when the new Agora was constructed (by Pellas or Pisistratus?), they took their meals in the Thesmotheum for the sake of convenience. There was also a court of justice called the court of the Prytaneum; all that is known of this court is that it tried murderers who could not be found, and inanimate objects which had caused death. Judging from its rather fanciful functions and from its name, it is probably a relic of the pre-historic jurisdiction of the patriarch-king.

2. For the Prytanes of the Boulé and of the Naucræs, see Boulé and Naucracy.

3. Prytaneia were court-fees paid when the prosecutor was claiming a part of the penalty which the defendant would be called upon to pay if he lost.

4. Prytanas was also the name of a legendary king of Sparta of the Eurypontid or Procolid line. He was the son of Eurypont and fourth in descent from Procles. 

PRZEMYŚL—PSALMS, BOOK OF

BIBLIOGRAPHY.—On the Frytanum as the centre of an ancient state see article FIRE, and references in a paper (s.v.) by Frazer (Journal of Philology, 1885, xiv. 28). For the site of the Athenian P. see E. Curtius, Attische Studien, and an article by Scholl (Hermeis, v. 340); also general histories of Galicia and of Poland, and was shortly also

PRZEMYŚL, a town of Austria, in Galicia, 66 m. W. of Lemberg by rail. Pop. (1900), 46,295, mostly Polish. It is situated on the river San and is one of the strongest fortresses in Galicia. Przemyśl is the seat of a Roman Catholic and of a Greek uniat bishop, and has a Roman Catholic cathedral, begun in 1460. The industries comprise the manufacture of machinery, liqueurs and spodum or taddy, the refining of naphtha, corn-milling and the sawing of timber. The trade is chiefly in timber, corn, leather and linen. On the hill above the town are the ruins of an old castle, said to have been founded by Casimir the Great. Przemyśl, one of the oldest towns in Galicia, claims to have been founded in the 5th century, and was at one time capital of a large independent principality. Casimir the Great and other Polish princes endowed it with privileges similar to those of Cracow, and it attained a high degree of prosperity. In the 17th century its importance was destroyed by inroads of Tatars, Cossacks and Poles.

PRZHEVALSKY, formerly Karakol (renamed in 1889), a town of Russian Turkestan, in the province of Semirechensk, 8 m. S.E. of Lake Issyk-kul. Nikolai Przhevalsky (Przevalsky q.v.), the Russian explorer in Central Asia, died here in 1889, and a monument has been erected to his memory. It is a growing town, and had in 1897 a population of 7985.

PSALMS (from the Gr. ψάλλειν, to play the harp), the name used to designate the religious poems of the Hebrews, which are contained in the Psalter (see Psalms, Book of). Modern collections of religious poetry sometimes bear the title of Psalms and Hymns, but these are always more or less directly connected with the actual Psalms of David. Longfellow wrote "A Psalm of Life" (1839), which was an intimate confession of the religious aspirations of the author. The Psalms of Clément Marot (1538) were curious adaptations of Hebrew ideas to French forms of the epic and the madrigal. But it is doubtful whether the psalm, as distinguished from the Hebrew Psalter, can be said to have any independent existence. It is loosely used to describe any exalted strain of devotional melody. (See also Hymns.)

PSALMANAZAR, GEORGE (c. 1679-1763), French adventurer, was born about 1679, probably in Languedoc. According to his own account he was sent in his seventh year to a free school taught by two Franciscan monks, after which he was educated in a Jesuit college "in an archiepiscopal city." On leaving college he became a private tutor. He assumed personations in order to obtain money, his first being that of a pilgrim to Rome. Afterwards he travelled through Germany, Brabant and Flanders in the character of a Japanese convert. At Liége he enlisted in the Dutch service, shortly after which he posed as an unconverted Japanese. At Sluyz he made the acquaintance of a Scottish chaplain, by whom he was brought over to England and introduced to the bishop of London. Having undergone conversion to Christianity, he was employed by the bishop to translate the Church catechism into what was supposed to be the Japanese language. In 1704 he published a fictitious Historical and Geographical Description of Formosa, and was shortly afterwards sent to Oxford. In 1707 he published Dialogue between a Japanese and a Formosan. There also appeared, without date, An Inquiry into the Objections against George Psalmanazar of Formosa, with George Psalmanazar's Answer. His pretensions were from the beginning doubted by many, and when exposure was inevitable he made a full confession. Throughout the rest of his life he exhibited, according to Dr Samuel Johnson, as reported by Mrs Piozzi, "a piety, penitence, and virtue exceeding almost what we read as wonderful in the lives of the saints." Psalmanazar published Essays on Scriptural Subjects (1753), contributed various articles to the Ancient Universal History, and completed Palmer's History of Printing. He died in London on the 3rd of May 1703. His memoirs appeared in 1764 under the title, Memoirs of... commonly known by the name of George Psalmanazar, but do not disclose his real name or the place of his birth.

PSALMS, BOOK OF, or Psalter, the first book of the Hagiographa in the Hebrew Bible.

Title and Traditional Authorship.—The Hebrew title of the book is תהלים, Pielhimmim, or תהלות "the book of hymns," or rather "songs of praise." The singular תהל is properly the infinitive or nomen verbi of בִּלְתָּם, a verb employed in the technical language of the Temple service for the execution of a jubilant song of praise to the accompaniment of music and the blare of the priestly trumpets (1 Chron. xvi. 4 seq., xxv. 3; 2 Chron. v. 12 seq.). The name is not therefore equally applicable to all psalms, and in the later Jewish ritual the synonym Hallel specially designates two series of psalms, cxiii.—cxviii. and cxviii.—xlviii., of which the former was sung at the three great feasts—the encaenia, and the new moon, and the latter at the daily morning prayer. That the whole book is named "praises" is clearly due to the fact that it was the manual of the Temple service of song, in which praise was the leading feature. But for an individual psalm the usual name is ישט (in the Bible only in titles of psalms), which is applicable to any piece designed to be sung to a musical accompaniment. Of this word ישט, "psalm," is a translation, and in the Greek Bible the whole book is called ψαλμοι or λαλατομοι. The title ψαλμοι or βυθικα ψαλμων is used in the New Testament (Luke xx. 44, xxiv. 44; Acts i. 20), but in Heb. iv. 7 we find another title, namely "David." Hippolytus tells us that in his time most Christians said "the Psalms of David," and believed the whole book to be his; but this title and belief are both of Jewish origin, for in 2 Macc. ii. 13 ην του θεου θεος means the Psalter, and the title of the apocryphal "Psalter of Solomon" implies that the previously existing Psalter was ascribed to David. Jewish tradition does not make David the author of all the psalms; but as he was regarded as the founder and legislator of the Temple psalmody (1 Chron., ut supra; Ezra iii. 10; Neh. xii. 36, 45 seq.; Ecclus. xlvii. 8 seq.), so also he was held to have completed and arranged the whole book, though according to Talmudic tradition he incorporated psalms by ten other authors, Adam, Melchizedek, Abraham, Moses, Heman, Jeduthun, Asaph, and the three sons of Korah. With this it appears that the titles of the psalms name no later than Solomon, and even he is not recognized as a psalmist by the most ancient tradition, that of the LXX., which omits him from the title of Ps. cxvii. and makes Ps. lxxii. be written not by him but of him. The details of the tradition of authorship show considerable variation; according to the Talmudic view Adam is author of the Sabbath psalm, xxiii., and Melchizedek of Ps. cx., while Abraham is identified with Ethan the Ezrahite (Psalms lixxx.). But, according to older Jewish tradition attested by Origen, Ps. xxi. is by Moses, to whom are assigned Ps. xc.-c. inclusive, according to a general rule that all anonymous pieces are by the same hand with the nearest preceding psalm whose author is named; and Ps. cx., which by its title is Davide, seems to have been given to Melchizedek to avoid the dilemma of Matt. xxii. 41 seq. Origen's rule accounts for all the psalms except i. and ii., which were sometimes reckoned as one poem (Acts xiii. 33 in the Western text; Origen; B. Berkhoff, i. 9b.), and appear to have been ascribed to David (Acts iv. 25).

The opinion of Jerome (Proef. in ps. heb.) and other Christian writers that the collector of the Psalter was Ezra does not seem to rest on Jewish tradition.

Nature and Origin of the Collection.—Whatever may be the value of the titles to individual psalms, there can be no question that the tradition that the Psalter was collected by David is not historical;

1 Hippol., ed. Lag., p. 188; Euseb. H.E. vi. 25, 2; Epiph. Mens et Pond. § 23; Jerome's preface to Psall. justa Hebraeos.
2 Similarly in the Syriac Bible the title is massařé.
3 The passages are collected in Kimhi's preface to his commentary on the Psalms, ed. Schiller-Szinessy, Cambridge (1883).
for no one doubts that some of the psalms date from after the Babylonian exile. The truth that underlies the tradition is that the collection is essentially the hymn-book of the second Temple; and it was therefore ascribed to David, because it was assumed, as we see from II Esdras x., that it was the work of David, and that the temple was the same as in the first, and had David as its father: as Moses completed the law of Israel for all time before the people entered Canaan, so David completed the theory and contents of the Temple service. But we cannot, therefore, understand its origin, or its later use in a way perfectly natural in a hymn-book, but rather otherwise intelligible. Such ancient hymns as Exod. xv. i seq., Judges v. 1 Sam. ii. i seq., are not included in the collection, though motives from them are embodied in more modern psalms: the interest of the collector, we see, was not historical but liturgical.

The question now arises: Was the collection a single act or is the Psalter made up of several older collections? And if we have first of all to deal with the Psalter as a whole, how many of its books are there—five, four, three? The Psalter consists of five books, each of which closes with a doxology. The scheme of the whole is as follows:

I. Book I. Ps. i.—xi.; all these are ascribed to David except i., ii., xxxix.—lxx. (ascribed to David in LXX.); doxology, xii. 13.

II. Book II. Ps. xii.—xlii.; of these xii.—xxix. are ascribed to the Korahites (xiii., being part of xii.), i. to Asaph, li.—lxxi. to David (except lxvi., lxvi., anonymous; in LXX., the list is divided); but it is followed by the subscriptions “The prayers of David the son of Jesse are ended.”

III. Book III. Ps. lxxii.—lxxxix.; here lxxiii.—lxxxix. bear the name of Asaph, lxxxiv., lxxx., lxxxv., lxxxvi., that is, there, lxvi.—lxxxvi., are the psalms of Asaph, lxxxvii.—lxxxix., the psalms of Ethan; doxology, lxxx. 5.

IV. Book IV. Ps. xcv.—cvii.; all these are anonymous except xc. (Moses), cii. (David).—LXX. gives also cv. to David; here the doxology is peculiar, “Blessed be Jehovah God most high; the name of the king is blessed among people.”

V. Book V. Ps. cviii.—cxvi.; of these cviii.—cxviii., cxxx., cxxvii., cxxxviii.—cxlv. are ascribed to David and cxvi. to Solomon, and cxxvi.—cxlv. are psalms of Asaph, like the others, incorporated into the Psalter as to the Hebrew, to be ascribed to David; the book closes with a group of doxological psalms.

The division into five books was known to Hippolytus, but a closer examination of the doxologies shows that it does not represent the original scheme of the Psalter; for, while the doxologies to the first three books are part of the psalms to which they are attached, but mark the end of a book in a more fashion not uncommon in Eastern books, the doxology to the fourth and fifth books, plainly belongs to the psalm, or rather to its liturgical execution, and does not therefore really mark the close of a collection once separate. In point of fact books IV. and V. have so many common characters that they may well be considered as forming a group. Again, the main part of books II. and III. (Ps. xlii.—lxxii.) is distinguished from the rest of the Psalter by habitually avoiding the name Jehovah (the Lord) and using Elohim (God) instead, even in cases like Ps. l. 7, where I am Jehovah thy God of Exod. 20: 19 is quoted but changed very awkwardly to “I am God thy God.” This is not due to the authors of the individual psalms, but to an editor: for Ps. lii. is only another recension of Ps. xiv., and Ps. lv. repeats part of Ps. xl., and here Jehovah is sinfully replaced by Elohim, while the opposite change happens but once. The Elohim psalms, then, have undergone a common editorial treatment, distinguishing them from the rest of the Psalter. And they make up the main part of books II. and III. Of the remaining psalms, lxvi.—cvii., appearing to be a sort of appendix. But when we look at the Elohim psalms more nearly, we see that they contain two distinct elements, Dasvidic psalms and psalms ascribed to the Levitical choir (sons of Korah, Asaph). The D avidic collection as we have it splits the Levitical psalmistic materials and actually begins with Ps. i. from the main Asaphic collection, lix.—lxxiii. This order can hardly be original, especially as the Davidic Elohim psalms have a separate subscription (Ps. lxvi.—cvii.). But if we remove them we get a collection of 153 psalms. From the nature of its headings and actually begins with Ps. i. from the main Asaphic collection, lix.—”lxxiii. This order, therefore, is much later than the Davidic collection, and seems to have been added by way of appendix by a non-Levitical editor. A supplementary group of Korahite psalms and one psalm (certainly later than the twelve) is added. The Psalter, therefore, is certainly later than the Davidic redaction and combination of (b) and (c); (e) the addition of a non-Levitical supplement to (d) with a doxology.; (f) a collection later than (d), consisting of books IV. and V. And finally the anonymous psalms i., ii., which as we have seen (p. 322) are an original part of book I., may have been prefixed after the whole Psalter was completed. We see, too, that it is only in the latest collection (books IV., V.) that anonymity is the rule, and titles, especially titles with names, occur only sporadically. The titles run in series and correspond to the limits of older collections.

Date of the Collection.—An inferior limit for the final collection is given by the Septuagint translation. This translation was not made so long as the LXX. of the Old Testament. It was, therefore, more than 150 b.c. to follow in its passing to the Greek-speaking Jews in Alexandria. Beyond this the external evidence for the completion of the collection does not carry us.

(W. R. S.)

But there is absolutely no necessity for supposing that when the grandson of Ben Sira reached Egypt the Psalter had been translated into Greek for any considerable time. Indeed it is impossible to say the others were so early be introduced. It is therefore possible that some of the poetic books of the Old Testament which were put, to a desire to translate his grandfather's book, and perhaps add the work of a man of the family to the Bible of the Egyptians. It appears indeed, from I Chron. xvi. 2 Chron. vi. 41, 42, that various psalms belonging to books IV. and V. were current in the time of the Chronicler. Unfortunately, however, it is impossible to date the book of Chronicles with certainty.

The argument that the Chronicler must have been contemporary with the last persons named in his book is by no means convincing and upon the other hand his account of the Temple services, in which he seems to be describing the Temple of his own days, harmonizes far better with a date at the end of the third, or even in the second, century B.C. than with the close of the Persian or the beginning of the Greek period. For the impression which we get from Nehemiah's memoirs is that in his days only poverty-stricken, while Nehemiah and the Chronicler the people and the Temple is oppressed, there that the priests implies that in the middle of the fifth century B.C. the Temple was by no means wealthy. But in the comparative peace and freedom of the 3rd century B.C. the condition of Jerusalem was greatly ameliorated. Wealth accumulated to such a degree that Simon the son of Onai was enabled practically to rebuild the temple, and to maintain its services with a grandeur of ritual which they had probably never known before. It must be admitted that the gorgeousness of ritual described by the Chronicler is far more in harmony with the days of Simon than with any previous post-exilic period. How late the Chronicler wrote cannot perhaps be determined; but it is, at all events, impossible to prove that the author of Ecclesiasticus was acquainted with his work. Ben Sira, indeed, in his list of worthy mentions Zerubbabel, Joshua and Nehemiah; but Zerubbabel and Joshua he must have known from the books of Hagai and Zechariah, and he may well have been acquainted with their expectation. Zerubbabel's opposition to the Chronicler is incorporated with his book. Ben Sira's own name, as in a name of Ezra rather militates against the supposition that he had the Chronicler's book before him when he wrote. The conflict between the Sadduceism and the sofherim was hardly so intense in his days as to warrant the supposition that he omitted the name of Ezra intentionally. Moreover, it is not certain that the psalms that the Chronicler quotes (xvii., cv., cxxvii., cxxxii.)

This is a passage obscure and in part corrupt; but the Latin "cum multum temporis ibi fuisse" probably expresses the author's meaning. A friend has written to the author for the 1 John xvi. 8-11 we ought perhaps to read epsk 1066, 1066.
already existed in their place in our Psalter, or that Ps. cxi. even existed in its present form.

One other evidence of date is to be found in the Levitical psalms of the Elohist collection. These, as we have seen, form two groups, referred to the sons of Korah and to Asaph. In Nehemiah xii. 46 Asaph is taken to be a contemporary of David and chief of the singers of his time, and in 1 Chron. xcv. 1 seq., one of the three chief singers belonging to the three great Levitical houses. But the older history knows nothing of an individual Asaph; in Ezra ii. 41 the gild of singers as a whole is called Bne Asaph, as it was apparently in the time of Nehemiah (Neh. xii. 22, Heb.). The singers or Asaphites are at this time still distinguished from the Levites; the oldest attempt to incorporate them with that tribe appears in Exod. vi. 24, where Abiasaph—that is, the eponym of the gild of Asaphites—is made one of the three sons of Korah. But when singers and Levites were fused the Asaphites ceased to be the only singers, and ultimately, as we see in Chronicles, they were distinguished from the Korahites and reckoned to Gershom (1 Chron. vi.), while the head of the Korahites is Heman, as in the title of Ps. lxxxviii. It is only in the appendix to the Elohist psalm-book that we find Heman and Ethan side by side with Asaph, as in the Chronicles; but this does not necessarily mean that the collection originated in two separate collections, for there are only two gilds of singers.

But wherever it becomes necessary to ask what is the precise meaning which we are to assign to the phrases, “to David,” “to Asaph,” “to the sons of Korah,” “the lxxv. if these had been the case, it is probable that the ascription would not have been prefixed to each separate psalm, but rather to the head of each collection (cf. Prov. i. 1, xxv. 1, lxxv. 1), together with some such note at the end as is found in Job. xxxi. 40, Ps. lxxvi. 20; moreover, it would be completely nugatory to the Oxford Dictionary to find that those psalms which have the heading לְֹדֵד (A. V. “to” R. V. “for” “the chief Musician”) also originally formed a separate collection. But against this explanation of the heading לְֹדֵד there is an almost insuperable objection; for, since both the first and second books contain psalms with this heading, it is clear that the “Chief Musician’s—or Director’s—Psalter” must have been in existence before any of these books; in which case, apart from the difficulty of the antiquity which we should be compelled to assign to this earliest Psalter, it is impossible to understand on what principle the first book of Psalms was formed. If the compiler of the first book aimed simply at organizing the material which had been collected by Ps. lxxvi. 20, but had not been committed to writing by the “Directors,” why should he have deliberately rejected a number of Davidic psalms (Ps. li. seqq.) which, ex hypothesi, lay before him in this Psalter? It is surely as difficult to suppose that the Elohist appended the first book to the post-exilic collection of some psalms contained in the “Director’s Psalter” as it is to imagine that St Mark’s Gospel is an abridgment of St Mark’s. It is true that the preposition “to” לְֹדֵד may denote authorship, as it does apparently in Isaiah xxxviii. 9, Hab. iii. 1, but it certainly has a much wider meaning; and indeed in some cases the idea of authorship is out of the question, for the psalms ascribed to the Korahites can scarcely have been supposed to be the joint composition of that body. Moreover, it is very doubtful whether the word לְֹדֵד can be translated “Director.” In 1 Chron. xv. 21 the verb of which לְֹדֵד is the participle is used of the duty which was discharged by Mattithiah, Eliephelehu, Mikenath, Obadod-edom, Joel and Aazaziah (and perhaps, according to verse 21, by Zechariah, Aziel, Shemiramoth, Jeiel, Unni, Eliah, Maseelah and Benaiah also) on one definite occasion. Unfortunately the exact nature of these men’s performances is not quite clear, for it is said to have been connected with “harp s set to the lute,” or according to another interpretation, with “harp s over the tenors.” But whatever the obscure expression תְֹדֵד תְֹדֵד may mean, לְֹדֵד cannot here mean to “direct,” for a choir with six “directors” would have been a veritable beargarden. Obviously the word לְֹדֵד must refer to something in the music: and inasmuch as the cymbals were for the purpose of producing a volume of sound (תְֹדֵד תְֹדֵד), it is reasonable to suppose that the

musicians with treble lutes and with harps an octave lower (or with lutes and harps over the sopranos and tenors respectively) were to lead the singers in giving out the melody. If this explanation be correct—and it certainly accords best with the meaning of מְדֵד in 1 Chron. xv. 21—the לְֹדֵד will be that part of the orchestra which played the melody to be sung, virtually corresponding, mutatis mutandis, to what we now call the rho organ, and we need not consider the cymbals as necessarily forming part of the “Director’s Psalter.”

Now we have seen that the prefixed לְֹדֵד cannot refer to authorship; we seem therefore shut up to one of two alternatives, either the psalms inscribed לְֹדֵד belonged to the répertoire of the Korahites, or they were intended to be sung in the Korahite style. It is indeed possible that each division of the Levitical singers had its own collection; but this is hardly probable unless we are to suppose that they were, as it were, similar to our modern choirs. It is quite certain that we have expected that the psalm quoted by the Chronicler (1 Chron. xvi.) would be included in the Asaphic collection. But there is no difficulty in supposing that each division of the Levitical musicians had its own tradition of music, certain instruments being peculiar to the one and certain to the other, in which case the assignment of a psalm to the Asaphites or Korahites will merely denote the sort of music to which it is set. In like manner it is not improbable that לְֹדֵד meant originally “to be sung in the Davidic mode,” that is, perhaps, “with harp accompaniment” (cf. I Sam. xvi. 16), or, since the lute is mentioned as the most common instrument, either “to be sung in the oldest traditional mode.” Under such circumstances, however, a confusion would easily arise between the composer of the tune and the author, and when once the idea had arisen that David was the composer of this particular psalm, the compiler was justified in disowning the former with the non-committal “in the oldest traditional mode.”

The interpretation of the titles here suggested removes an objection brought against the assumption of a Maccabean date for certain psalms, which lays stress on the fact that some of them, e.g. Ps. xlvi., are written in a time of the deepest depression, and yet are psalms of the Temple choirs; whereas, when the Temple was re-opened for worship, after its profanation by Antiochus, the Jews preserved a general apophasis, and the use of the term “Send in the story of his life suitable occasions for their composition.

Since, then, the existence of separate books of psalms anterior to the present divisions of the Psalter is very doubtful, we can look for other evidences of date. Now, both the Korahite and Asaphic groups of psalms are remarkable that they hardly contain any recognition of present sin on the part of the community of Jewish faith—though they would both have been suitable to the circumstances of the time—Furthermore, though the first of these groups contains no prediction of the coming of the Messiah, it is hardly possible that the psalms quoted by the Chronicler belong to the last collection, books IV. and V., which, as a whole, is far more suitable for liturgical use.

The first collections of psalms may well have been used first in synagogues, and only adapted to the Temple worship when they had become part of the traditional life of the people. It is noteworthy that the psalms quoted by the Chronicler belong to the last collection, books IV. and V., which, as a whole, is far more suitable for liturgical use.

Some confirmation of this explanation of the titles may be found in the fact that in place of מְדֵד (Ps. xxxix. 1) we find in lxxii. i, lxxvi. i, מְדֵד, the latter expression being an abbreviation of מְדֵד מְדֵד.
century, B.C.). But there is no evidence that the Jews were involved in these; for the account which Josephus gives of Bopges’s oppression of the Jews represents the trouble as having arisen originally from internal dissensions, and does not hint at anything of the national rebellion of the Persians. Moreover, the breach of Eusebius (Chron., anno 1658 A.D.) that Artaxerxes Ochus in the course of his campaign against Egypt transported a detachment of Jews to Hycaria does not prove that Judea as a whole was revolted. There is no evidence that the Jews of the present day in Persia or in any part of the Orient may have formed a part of the very considerable Jewish community which we know to have been settled in Egypt as early as the 5th century B.C. On the other hand, it is extremely improbable that the Jews of the time of Nehemiah had entirely abandoned their immediate neighbours, would have taken part in any general rising against Persia. Between them and the Samaritans on the north and the Edomites on the south there was the most implacable of all the Jewish enemies of the Jewish nation, and the Edomites from joining in the revolts in which other parts of Syria were involved. Moreover, even if the Jews had revolted, it cannot fairly be maintained that such a revolt must necessarily have had a religious cause. Nehemiah says that the Persians tried to interfere with the Jews in the exercise of their religion; and nothing less than this would satisfy the language of Ps. xlv. 22: “Yea, for thy sake are we killed all the day long,” etc. On the other hand, not only is the atmosphere of the second collection of psalms as a whole the atmosphere of godly Judaism in the 2nd century B.C., but it may fairly be claimed that this collection contains many psalms which may naturally be interpreted in the light of the history of the time of Nehemiah, and therefore it is perfectly satisfactory to suppose that these psalms can be given if they are assigned to any other time. Thus, for example, Ps. xlv., with its description of the sufferings of the righteous for God’s sake, would be perfectly appropriate in the mouth of Nehemiah himself to answer the claims of Nehemiah and the community which he represents. Moreover, this collection would be appropriate as addressed to an Egyptian princess whose forefathers, though their rule had not on the whole been tyrannical, had been regarded by the Jews as heathen oppressors. Again, Ps. lx., with its description of a youthful commerce between the land of Samaria, Moab, Edom and Phœalia, the ideal of the rule of John Hyrcanus, would be quite appropriate in the mouth of a Maccabæan patriot. The author of Ps. lviii., would seem to have been moved by an experience which was quite as great a shock to the Jews of his time as was the triumph of the Egyptians in 164 B.C. to dedicate the desecrated Temple. Hence the taunt to Bashan, the stronghold of the Seleucid government; hence the mention of Judah and Benjamin with the two Galilæan tribes Zebedon and Naphatli (as in Isaiah ix. 1—a passage which on independent grounds has been assigned to the time of Simon Maccabæus), while schismatic Samaria is completely ignored. The historical background of the composers in this part of the collection is slight. Again, Ps. lxxxvii., would seem to date from a time when the Jews, having won freedom to worship God, were able to look forward to the conversion of their former oppressors (cf. Isaiah xi. xix.). This psalm describes the joy and triumph with which the Jews look forward to the day when the prince of the Assyrians (for who else but Sennacherib, the conqueror of Samaria, is here referred to?) shall be scattered among the nations. The sameness of the language and tone, is another point which makes it probable by the name here given to Egypt, Rahab. Having regard to Job. ix. 13, xxxvii. 12, Isaiah lii. 9, there can be little doubt that Rahab is the (Palestinian) name of Ta’mat the dragon of the abyss, that is, the representative symbol of the power of darkness, or of darkness itself, as referred to in the whole of the world as opposed to the kingdom of the people of the saints of the Most High God. It is extremely improbable that such a name was applied to Egypt simply because Egypt possessed the crocodile. The origin of its application must be sought in a period when Egypt was regarded as hostile to the people of the Lord—that is to say, during the Ptolemaic rule over Palestine. These considerations, in addition to numerous phrases and expressions which come from the same period, make it probable that Ps. lxxxvii. was made by one who had studied the Maccabæan period and those other portions of the Old Testament, such as Zechariah ix.—xiv., which may plausibly be assigned to it, make it almost certain that this psalm belongs to the very earliest period. It was made not earlier than the time of Jonathan or even of Simon.

Now books IV. and V. are, as we have seen, later than the Elohist reductio of books II. and III., so that the collection of the last part of the Psalter must, if our argument up to this point is sound, fall within the limits of the time of Nehemiah. And it may be noted that though not part of the Psalter shows clearer marks of a liturgical purpose, we find that in books IV. and V. the musical titles have entirely disappeared. This does not necessarily prove that the Psalter was not in use before the time of Nehemiah; it may be simply that the Psalter was already so well known to be religious, as to be handed down to the next generation purely from generation to generation, without the addition of any musical phrase. It cannot have been by reason of the musical titles, however, may be taken as an indication that the last collection of psalms was formed in a different place from that in which the earlier collections had arisen; and if, as seems probable, we may identify this place with the Temple at Jerusalem, the absence of musical titles is easily explained, for the number of skilled musicians who there ministered, amounting to as many as six hundred, was much greater than of the naturalists of the Persian period. Moreover, the Psalter was of course meant to be sung, and if the Psalms were not already provided with a musical notation, it would be desirable to state whether the psalm was to be sung to a Davidic, Asaphic or Korahite tone, or to give the name of a melody appropriate to it. Again, the general tone of large parts of this collection is quite different from that of the Elohist Psalms. This is especially true of Psalms which begins with a psalm (xxc.) ascribed to the title to Moses, and seemingly designed to express feelings appropriate to a situation analogous to that of the Israelites when, after the weary march through the wilderness to the Red Sea, they looked back on a time of great trouble and forward to a brighter future. In some of the following psalms there are still references to deeds of oppression and violence, but more generally, Israel appears as happy under the law. The problems of divine justice are for the most part questions, the righteousness of God is seen in the peaceful felicity of the piou (xxcii., xxciii., &c.). Israel, indeed, is still scattered and not triumphant over the heathen, but even in the dispersion the Jews are under a mild rule (xxxvii.), and the commercial activity of the nation has begun to develop beyond the seas (cvii. 26 seq.). But some of the psalms refer to a time of struggle and victory. In Ps. cviii. Israel, led by the house of Aaron—this is a notable point—has been victorious, and thus the author of Ps. cviii. is at the Temple a great day of rejoicing for the unhoped-for victory: in Ps. cxlix. the saints are pictured with the praises of God in their throat and a sharp sword in their hands to take vengeance on their oppressors. In Ps. cxxvi. the important points to us are the relationships of the Psaumes to the collection of Psalms in the Ptolemaic library at Denderah. This collection is, as we have seen, an entirely different one from any of the other collections of Psalms; and Psalms cxxvi. onwards, may be considered as part of this library. It is quite possible that there is here to be discovered a collection of Psalms which forms a link between the Psalter as we possess it and the Psalms in the Ptolemaic library at Denderah. In the Psalter as we possess it it is extremely improbable that such a name was applied to Egypt simply because Egypt possessed the crocodile. The origin of its application must be sought in a period when Egypt was regarded as hostile to the people of the Lord—that is to say, during the Ptolemaic rule over Palestine. These considerations, in addition to numerous phrases and expressions which come from the same period, make it probable that Ps. cxxvi. was made by one who had studied the Maccabæan period and those other portions of the Old Testament, such as Zechariah ix.—xiv., which may plausibly be assigned to it, make it almost certain that this psalm belongs to the very earliest period. It was made not earlier than the time of Jonathan or even of Simon.

The titles which ascribe four of the pilgrimage songs to David and one to Solomon are all later than the Redaction of the Psalter and the contents of the psalms. Better attested, because found in the LXX. as well as in the Hebrew, and therefore probably as old as the collection itself, are the name of Moses in Ps. xc. and that of David in Ps. cvii. This has led some scholars to the last collectors of the psalms find such very ancient pieces which had been passed over the psalms of which the Psalms book has been formed.
PSALMS, BOOK OF

538

When Abimelech (the Philistine king in the stories of Abraham and Isaac) could be substituted in the title of Ps. xxiv., for Achish, king of Gath. In a word, the ascription of these two collections to David has none of the characters of a genuine historical tradition.

It is clear that the two collections do not stand on quite the same footing. The second collection of "Davidic" psalms, as well as the Korahite and Asaphic psalms, have been subjected to an Elohistic redaction, for which we must find a reason. By all accounts, the edition of the Targum in the Masoretic Hebrew is an accumulation of fragments, the latest of which is the Targum of Onkelos, which is naturally suggested itself that, at the time when books II. and III., with the exception of the appendix, Ps. lxxiv.,-lxxviii., were collected, it was already the custom, from motives of reverence, to abate from pronouncing the Tetragrammaton. Upon this subject the view is sometimes expressed that the El of Job and the other scriptures arose, and books IV. and V. when the custom had arisen of substituting in reading the word Adonai. But, as we have seen, it is impossible to separate the contents of the Elohistic books from those of the Davidic, and as a matter of fact the El is nowhere understood as referring to the designation of Antiochus Epiphanes and to the Maccabean victories, and cannot therefore be separated by a long interval of time. Moreover the scripture as to the professed date of the Tetragrammaton seems to have arisen earlier, as in the LXX, version of the Pentateuch is represented by Κυρίος. And further, if the Elohistic redaction was due merely to a desire to avoid pronouncing the divine name, why was not the presumably older Ps. i., IV., and V., which are in the El mode throughout, given a similar treatment? It is therefore difficult to suppose that the Jewish Church as a whole passed through a stage in which it was felt desirable to substitute Κυρίος for Ps. i., IV., and V. There is, however, no difficulty in supposing that such a thing was done in some sections of the Jewish Church, and it is probable that we must look for an explanation of the peculiarity of the Psalter of the LXX to the fact that the El collection was formed. Now it must be frankly admitted that the earlier books of psalms exhibit no particular suitability for the Temple services. It is only in the last collection, books IV. and V., that we find a fitting sequel. In the LXX, the El collection is placed after the Temple psalms, rather, according to the oldest tradition, "for Solomon," is composed of "Davidic" psalms. It would seem also that the collectors of books I.-III. know of no Davidic psalms outside of these two collections. In the LXX, the El collection is merely a conglomeration of psalms, a curious mixture of psalms, which are not from one psalm-book, and of which several, as the epistle to the Philippians, are possibly from an appendix. The El collection of the Psalter was inserted in the book of Samuel since it was written. If, as is possible, II. Kings, xxvii. 9 is a reminiscence of Ps. ii, and Ps. xxvii. 7-9 is a reminiscence of Ps. ii, Ps. xxvii. 10-15 is a reminiscence of Ps. i, and Ps. xxvii. 16-25 is a reminiscence of Ps. xxvii. 10-15, it is possible that this tradition of El collection in the LXX was made as early as the author of any of the psalms. Even the Chronicler, though he regarded David as the great founder of the Temple music, does not quote any psalm as composed by him, and the Chronicler’s omission of the following psalms is explained by the absence of them in the collection of Davidic psalms which was interpolated in the book of Samuel since it was written. It is, moreover, possible that the Chronicler may have had only a fragmentary knowledge of the psalms which were added to the book of Samuel since it was written. It is possible that this tradition of the El collection in the LXX was made as early as the author of Ps. i, and Ps. xxvii. 10-15 is a reminiscence of Ps. i, and Ps. xxvii. 16-25 is a reminiscence of Ps. xxvii. 10-15, it is possible that this tradition of El collection in the LXX was made as early as the author of any of the psalms. Even the Chronicler, though he regarded David as the great founder of the Temple music, does not quote any psalm as composed by him, and the Chronicler’s omission of the following psalms is explained by the absence of them in the collection of Davidic psalms which was interpolated in the book of Samuel since it was written. It is possible that the Chronicler may have had only a fragmentary knowledge of the psalms which were added to the book of Samuel since it was written.

In any case the titles are manifestly the product of the same uncritical spirit as we have just been speaking of, for not only are many of the titles apocryphal, but the fact that in other cases the titles would be placed before the author of any of the psalms. Even the Chronicler, though he regarded David as the great founder of the Temple music, does not quote any psalm as composed by him, and the Chronicler’s omission of the following psalms is explained by the absence of them in the collection of Davidic psalms which was interpolated in the book of Samuel since it was written. It is possible that the Chronicler may have had only a fragmentary knowledge of the psalms which were added to the book of Samuel since it was written.

Nothing can be further removed from this any possible situation in the life of the David of the books I.-III., or Ps. cxlix. and cxxx., the righteous people of God suffering in silence at the hands of the wicked, is the other hope than patiently to wait for the intercession of Jehovah (Ps. xii, xxvii., xxxvii., xxxviii., &c.). Nothing can be further removed from this any possible situation in the life of the David of the books I.-III., or Ps. cxlix. and cxxx., the righteous people of God suffering in silence at the hands of the wicked, is the other hope than patiently to wait for the intercession of Jehovah (Ps. xii, xxvii., xxxvii., xxxviii., &c.). Nothing can be further removed from this any possible situation in the life of the David of the books I.-III., or Ps. cxlix. and cxxx., the righteous people of God suffering in silence at the hands of the wicked, is the other hope than patiently to wait for the intercession of Jehovah (Ps. xii, xxvii., xxxvii., xxxviii., &c.). Nothing can be further removed from this any possible situation in the life of the David of the books I.-III., or Ps. cxlix. and cxxx., the righteous people of God suffering in silence at the hands of the wicked, is the other hope than patiently to wait for the intercession of Jehovah (Ps. xii, xxvii., xxxvii., xxxviii., &c.). Nothing can be further removed from this any possible situation in the life of the David of the books I.-III., or Ps. cxlix. and cxxx., the righteous people of God suffering in silence at the hands of the wicked, is the other hope than patiently to wait for the intercession of Jehovah (Ps. xii, xxvii., xxxvii., xxxviii., &c.). Nothing can be further removed from this any possible situation in the life of the David of the books I.-III., or Ps. cxlix. and cxxx., the righteous people of God suffering in silence at the hands of the wicked, is the other hope than patiently to wait for the intercession of Jehovah (Ps. xii, xxvii., xxxvii., xxxviii., &c.).
and of this last passage it may be said that all the translatable portions of it can be naturally explained, if it refers to the time when the resistance of the Hashdìm, whom the Sadducees had despised and shunned, had won freedom for Israel as a whole, and at no other known time in the history of Psalms. Psalms xlvii. 3, is the only psalm which, at the time the Lord who had shown Himself strong and mighty by His victories over the heathen returned in triumph to His Temple in 164 B.C.—in the days of Zerubbabel or of Nehemiah had not directly shown Himself "I am." In the light of these circumstances—and space here forbids more than the scantiest reference—we may reasonably suppose that the first book, with the exception of Ps. i., ii., and possibly xxxiii., is a collection of psalms prepared by the priests, and embodied in the Judaean synagogue in the earlier days of the Maccabean victories.

We have already noticed the difficulty of supposing that the Elothistic Psalter was compiled in a place where a Jehovahistic Psalter was already in use. It is therefore probable that the second collection (books IV. and V.) which may reasonably be assigned to the time when the Temple was desecrated, and when the people were passing the night in gazing at the stars and calling on God in prayer; his words, if they do not exactly fit anything in the later ritual, are well fitted to illustrate the original liturgical use of Ps. viii., xxxiv.

Some of the Jewish traditions as to the use of particular psalms have been already cited; it may be added that the Mishna (Talmid) assigns to the service of the continual burnt-offerings the following weekly cycle of psalms.—(1) xxiv., (2) xliii., (3) lxxxiii., (4) cxxv., (5) lxxxi., (6) xclii., (7) xxiv., as the title. Many other details are given in the treatise Seférim, but these for the most part refer primarily to the synagogue service after the destruction of the Temple. For details on the liturgical use of the Psalter in Christendom the reader may refer to Smith's Dict. Chr. Ant., s.v. "Psalmody."

Ancient Versions.—(A) The oldest version, the LXX, follows a text generally closely corresponding to the Massoretic Hebrew, the main variations being in the titles and in the addition (lacking in some MSS.) of an apocryphal psalm ascribed to David when he fought with Goliath. Ps. ix. and x. are rightly taken as one psalm, but conversely Ps. cxviii. is divided into two. The LXX. text has many "daughters," of which may be noticed (a) the Memphitic (ed. Lagarde, 1872); (b) the old Latin, which as revised by Jerome in 383 after the current Greek text forms the Psalterium romanum, long read in the Roman Church and still used in St Peter's; (c) various Arabic versions, including that printed in the polyglots of Le Jay and Walton, and two others of the four exhibited together in Lagarde's Psalterium, Joob, Proverbia, arabice, 1876; on the relations and history of these versions see G. Hoffmann, in Jenaer Literatur., 1876, art. 539; the fourth of Lagarde's versions is from the Peshito. The Hexaplar text of the LXX., as reduced by Origen into greater conformity with the Hebrew by the aid of subsequent Greek versions, was further enriched by the mother (d) of the Psalterium gallicanum—that is, of Jerome's second revision of the Psalter (385) by the aid of the Hexaplar text; this edition became current in Gaul, in the match was taken to the Vulgate; (e) of the Syro-Hexaplar version (published by Baethgen, 1846) and Casimiri, the famous Cambrosian MS. by Ceriani, Milan, 1874.) (B) The Christian Arabic version or Peshito (P'shtu) is largely influenced by the LXX., compare Baethgen, Untersuchungen über die Psalmen nach der Peshitta, Kiel, 1878 (unfinished).

1 Of the various explanations that have been given of Selah the only one which possess any probability is that given independently by Baethgen and others, viz. that it is a mispronunciation of an Aram. or Phoen. term, "al šāliḥ," shaliḥ, sallāh, used, especially by some Greek handmaster, was presumably an instruction for a musical interlude. The LXX. translators who render it by μετάφρασις though not recognizing the derivation of the word, knew its meaning.

K. H. K.
This version has peculiar titles taken from Eusebius and Theodore of Mopsuestia (see Nestle, in Theol. Literatur, 1876, p. 283). (C) The Jewish Aramaic version or Targum is probably a late work.\footnote{The most convenient edition is in Lagarde, Hagiographa chaldauce, 1873. (D) The best of all the old versions is that made by Jerome after the Hebrew in 405. It did not, however, obtain ecclesiastical currency—the old versions holding their ground, just as English churchmen still read the Psalms in the version of the “Great Bible” printed in their Prayer Book. This important version was first published in a good text by Lagarde, Psalterium juxta hebraeos hieronymi (Leipzig, 1874). Exegetical Works.—While some works of patristic writers are still of value for text criticism and for the history of early exegetical tradition, the treatment of the Psalms by ancient and medieval Christian commentators is a whole in which the patristic and the medieval are mingled. Only a small portion of these commentaries has been collected and published in the Critical and Exegetical Commentary on the Psalms, vol. i. (1906), vol. ii. (1907), in International Critical Commentary. (R. H. K.)}

The Psalter.

Origin of the Psalter, Bangton Lectures (1891), and the article Psalms (in Ency. Bib., 1902); Bickell, Die Dichtungen der Hebret (3 der Psalter, 1883), from a revised and metrically arranged text; Baethgen, in Nowack’s Hand-Komm. (1892); Wellhausen, in Sacred Books of the East, vol. xxvi. (trans. by Furness, J. Taylor and Paterson, 1898); Duhm, in Marti’s Kurzer Hand-Comm. (1899); Kirkpatrick, in Cambridge Bible for Schools (1893–1895); W. T. Davison, in Hastings’s Dict. Bible (1902); Driver, The Parallel Psalter (1904); C. A. and E. G. Bridges, Critical and Exegetical Commentary on the Psalms, 1886 (2nd ed., 1887 in Rosenmuller’s date (2nd half of the 2nd quarter, however, for this Prophet) (1865), was it the case that Olshausen, in the Testament. Of the recent works on the Psalms, which were published in the 1880s and 1890s, considered the Psalms as a whole, the most useful and best known of the Psalms was Fr. Psalterion written by Pelonuzzi, 1882 (2nd ed., 1885), and Olshausen’s (1883). To these may be added including general commentaries on the Old Testament as a whole, but not the Psalms (Prophetae Hierosolymitanae, 1836, 1836–1837), that of Delitzsch (1859–1860), then in shorter form, in several editions since 1867: Eng. trans., 1871, and that of Husfeld (2nd ed., by Riehm, 1867, 2 vols.). The last-named work, though lacking the historical and critical judgement of the earlier, was still convenient and useful, and has had an influence perhaps disproportionate to its real exegetical merits. The question of the text was first properly raised by Olshausen, and has since received special attention from, among others, Lagarde, Targumische Hymnen (Kohl, 1872, p. 46 seq.), Dyserink (in the “schola” to his Dutch translation of the Psalms, Theol. Tijdschr., 1878, p. 270 seq.), and Bickell (Carmina V. T. terrific., &c., Innsbruck, 1882), whose critical services are not to be judged merely by the measure of assent which his methodical treatment of the Psalms, though in his day the former, and Scholia still be consulted with advantage, but for most purposes Rosenmüller’s Scholia in Psalms (2nd ed., 1831–1822) superseded the necessity of frequent reference to the predecessors of that industrious commentator. Among the works of older Christian scholars since the revival of letters, the commentary of Calvin (1557) full of religious insight and sound theological appreciation of the text, still remains of lasting value. For the modern period, there may still be consulted for example, Robertson’s Commentary on the Psalms (1885), which was written by a man whose knowledge of the Targum, and the curious Italian istromento di porco, were the latest types to survive. In these latter forms the vibrating length of the strings was regulated by means of two wooden bridges, the upper bridge being a little above the lower, which in a string held in an upright position against the chest of the performer, until, owing to the increasing number of strings, it grew too cumbersome, and was placed flat on a table or on the knee. The German zither is the sole European survivor of the medieval psalter.
PESELLUS—PSEUDO-PERIPERTAL

represent this combination of rulers. If the dynasties were numbered thus before Manetho, the numeral may be the cause of Herodotus's confusion. After his father's death Psammetichus I. (664-610 b.c.) was able to defy the Assyrians and the Ethiopians, and during a long reign marked by intimate relations with the Greeks restored the prosperity of Egypt. The short reign of the second Psammetichus (594-589 b.c.) is noteworthy for the graffiti of his Greek, Phoenician and Carian mercenaries at Abu Simbel (q.v.). The third of the name was the unfortunate prince whose reign terminated after six months in the Persian conquest of Egypt (525 b.c.). It has been conjectured that the family of the Psammetichus was of Libyan origin; on the other hand, some would recognize negro features in a portrait of Psammetichus I., which might connect him with the Ethiopian rulers. See above, EGYPT: History; on the name, F. Ll. Griffith, Catalogue of the Egyptian mummy papers; the portrait, H. Schäfer in Zeitschrift für ägyptische Sprache, xxxiii. 116.

PESELLUS (Gr. Φιλοις), the name of several Byzantine writers, of whom the following may be mentioned:—

1. Michael Pселlus the elder, a native of Andros and a pupil of Photius, who flourished in the second half of the 9th century. His study of the Alexandrine theology, as well as of profane literature, brought him under the suspicion of the orthodox, and a former pupil of his, by name Constantine, accused him in an elegiac poem of having abandoned Christianity. In order to perfect his knowledge of Christian doctrine, Psellus had recourse to the instructions of Photius, and then replied to his adversary in a long iambic poem, in which he maintained his orthodox views, of which a copy is preserved in MSS.

2. Michael Constantine Pселlus the younger, born in 1018 (probably at Nicomedia; according to some, at Constantinople) of a consular and patrician family. He studied at Athens and Constantinople, where he became intimate with John Xiphilinus. Under Constantine Monomachus (1042-1054) he became one of the most influential men in the empire. As professor of philosophy at the newly founded academy of Constantinople he revived the cult of Plato at a time when Aristotle held the field; this, together with his admiration for the old pagan glories of Hellas, aroused suspicions as to his orthodoxy. At the height of his success as a teacher he was recalled to court, where he became state secretary and vestarch, with the honorary title of Τσατσ τῶν Φιλολόγων (prince of philosophers). Following the example of his friend Xiphilinus he entered the monastery of St. Andrew in the Suburbium of Constantinople. Michael, but, finding the life little to his taste, he resumed his public career. Under Isaac Commnenus and Constantine Ducas he exercised great influence, and was prime minister during the regency of Eudocia and the reign of his pupil Michael Parapinacines (1071-1078). It is probable that he died soon after the fall of Parapinacines.

Living during the most melancholy period of Byzantine history, Psellus exhibited the worst faults of his age. He was servile and unscrupulous, weak, fond of intrigue, intolerably vain and ambitious. But as a literary man his intellect was of the highest order. In the extent of his knowledge, in keenness of observation, in variety of style, in his literary output, he has been compared to Voltaire; but it is perhaps as the forerunner of the great Renaissance Platonists that he will be chiefly remembered. His works embraced politics, astronomy, medicine, music, theology, jurisprudence, physics, grammar and history.

Of his works, which are very numerous, many have not yet been printed. We may mention: Chronographia (from 976-1077), which in spite of its bias in favour of the Ducases is a valuable history of his time, chiefly on domestic affairs; three Epitaphii or funeral orations over the partisans Cassiopius and Xiphilinus of Michael. His letters (nearly 500 in number) are also full of details of the period. A complete list of his works is given in Fabricius, Bibliotheca graeca, x. 4); the most important have been published by C. Sathas in his Monumenta doxographorum iv. v. On Psellus himself see Leo Allatius, De Psellis et eorum scriptis (1634); E. Egger in Dictionnaire des sciences philosophiques (1875); A. Rambaud in Revue historique (1877); P. V. Beobrazov, Michel Psellus (1890) in Russian; C. Neumann, Die Weltstellung des byzantinischen Reiches vor den Kreuzzügen (1891); C. Krumbacher, Geschichte der byzantinischen Literatur (1897); J. E. Sandys, Hist. of Classical Scholarship (1906), i. 411.

Pseudo-Dipteral (Gr. Ψευδόπεπτης, false, διπτήρα, double, and πτέρων, a wing), the term given to a dipteral temple, i.e. in which there are two rows of columns round the naos, the inner row of which has been omitted to give more space for the processions or for shelter (see Temple).

Pseudonym (Gr. ψευδόνυμος, having a false name, ψευδός, false and νομός, name), a false or invented name, particularly the fictitious name under which an author produces his work in order to conceal his identity. The same end is gained by publication without any name, i.e. anonymously (Gr. ἄνωνυμος, without a name). The body of works thus produced either without the author's name or under a fictitious name is known as anonymous and pseudonymous literature, and many books have been published affording a key to the identity of the various writers, forming an important section of bibliography. Though Fredericus Geiser published a short treatise on the subject entitled Lautra derlec, &c., in 1660, the chief early work was that of Vincent Placcius (1642-1699) whose Theatrum pseudonymorum was published in 1708, edited by L. F. Vischer with a preface and life by J. A. Fabricius; supplements were published in 1711 and in 1740. The next important work, only a fragment of the proposed scheme, was that of Adrien Bailleul (q.v.), under the title of Auteurs déguisés sous les noms étrangers, &c. (1690). Antoine Alexandre Barbier (q.v.) published his standard work Dictionnaire des ouvrages anonymes et pseudonymes in 1806-1809 (2nd ed., 1822-1827). This was followed by the Supercieries littéraires dévoilées of J. M. Querard (q.v.). The third edition of Barbier's work, embodying Querard and much new matter, was published in 1872-1879. This was edited by P. Gustave Brunet, who published a supplement in 1889. Other works in French are those of C. Jollet, Les Pseudommes du jour (1867 and 1884); and F. Dujon, Listes à clef (1888). Of German works in this sphere of bibliography the Index pseudonymorum, Wörterbuch der Pseudonymen of Emil Weller appeared in 1856, of which several supplements were published later. The most monumental of all works are the Deutsches Anonymen- Lexikon, 1901-1895, by M. Holzmann and H. Bohatta (1902-1907), supplement, 1851-1908 (1909), and the Deutschem Pseudonymen-Lexikon, by the same authors (1906). See also F. Sintenis, Die Pseudonyme der neueren deutschen Literatur (1899), and the supplementary volume (1909), to Meyers Konversations-Lexikon (6th ed.). The chief Italian work is the Dizionario di opere anonomi e pseudonimi di scrittori italiani, by G. Molz (1848-1859), with supplement by G. Passano (1887). The Dutch Vervormde en naamloze schrijvers ... der Neder, en Vlaamse, letters, by J. I. van Doorninck (1883-1885), was a second edition of an earlier work. The Academy of Upsala is publishing, under the editorship of L. Bygden, a Swedish dictionary Svenskt anonym och pseudonym lexikon (1898), &c. England was late in entering the field. The first work actually published was the Handbook of Fictitious Names, by R. Thomas (Olpham Hamst) (1868). Samuel Halkett, and the successor to his compilations, John Laing, both died before their work was published; edited and revised by Miss C. Laing it appeared in 1882-1888 in 4 vols. as the Dictionary of the Anonymous and Pseudonymous Literature of Great Britain, by S. Halkett and J. Laing. This remains the standard work on the subject in English. Other works are W. Cushing, Initials and Pseudonyms (American and English from the beginning of the 18th century); 2nd series (1886, 1888), and Anonymous (1898); F. Marchmont, A Concise Handbook of Literature Issued under Initials or Pseudonyms (see also especially W. P. Courtney, The Secrets of Book and Journal Literature, 1815-1847, which contains a sketch of the history of the subject, to which the above account is mainly due. The anonymous and pseudo- nymous Latin literature of the middle ages has been treated in modern times by A. Franklin, Dictionnaire des noms, &c., latins 1100-1550 (1875), and A. G. Little, Initia operum latinorum saec. 13-15 (1904).

Pseudo-Peripteral (Gr. ψευδόπεπτης, false, πεπτης, round, πτερών, a wing), a term in architecture given to a temple in which the columns surrounding the naos have had walls built
PSUEDOPOD—

between them, so that they become engaged columns, as in the
great temple at Agrigentum. In Roman temples, in order to
increase the size of the cells, the columns on either side and at
the rear became engaged columns, the portico only having isolated
columns. (See Temple.)

PSUEDOPOD, Pseudopodium, the name given to an
tension of the naked protoplas of certain Protozoa, notably the
Sarcodina (q.v.), for crawling or creeping or for the prehension
of food, but not for active swimming (see also Amoeba).

PSILOMELANE, a mineral consisting of hydrous manganese
oxide with variable amounts of barium, potassium, &c. It is
sometimes considered to be a hydrous manganese nathanate, but
doing double composition. The amount of manganese present
contains at 70-80% of manganese oxide with 10-15% of “available” oxygen. The mineral is amorphous and occurs as
botryoidal and stalactic masses with a smooth shining surface
and submetallic luster. The name has reference to this char-
teristic appearance, being from the Greek φυλός (naked, 
smooth) and μέλας (black); a Latinized form is calvignitrite,
and a German name with the same meaning is Schwarzer Glasskopf.

Psilomelane is readily distinguished from other hydrous mangane
ese oxides (magnanate and wad) by its greater hardness (H. = 3½);
the sp. gr. varies from 3.7 to 4.7. The streak is browns-
black and the fracture smooth. Owing to its amorphous nature,
the mineral often contains admixed impurities, such as iron
hydrates. It is soluble in hydrochloric acid with evolution of
chlorine. It is a common and important ore of manganese,
occuring under the same conditions and having the same com-
mmercial applications as pyrolusite (q.v.). It is found at many
localities; amongst those which have yielded typical botryoidal
specimens may be mentioned the Restormel Iron mine at
Lostthiel in Cornwall, Brendon Hill in Somerset, Hoy, in the
Orkneys, Saxon near Coblenz, and Crimora in Augusta county,
Virginia. With pyrolusite it is extensively mined in Vermont,
Virginia, Arkansas and Nova Scotia.

PSKOV, a government of the lake-region of north-west Russia,
which extends from Lake Peipus to the source of the west Dvina,
having the governments of St Petersburg and Novgorod on the
N., Tver and Smolensk on the E., Vitebsk on the S. and Livonia
on the W. It has an area of 17,064 sq. m. In the south-east it
extends partly over the Alau or Vorobievoy heights, which stretch
west into Vitebsk and send to the north a series of irregular
ranges which occupy the north-western parts of Pskov. A
depression 120 m. long and 35 m. broad, drained by the Lovat
and the Polista, occupies the interval between these two lilly
tracts; it is covered with forests and marshes, the only tracts
suitable for human occupation being narrow strips of land
along the banks of the rivers, or between the marshes, and no
communication is possible except along the watercourses.

With the exception of the south-eastern corner, where Carboni-
ferous rocks crop out, nearly the whole of the government consists
of Devonian strata of great thickness, with deposits of gypseum
and white sandstone, the latter extensively quarried for building
purposes. The bottom: moraine of the Scandinavian and Finnish
ice-sheet formerly extended over the whole of this region, and
has left behind it numerous ridges (kames or eskers), the upper
parts consisting of Glacial sands and post-Glacial clays, sands
and peat-bogs. The soil is thus not only infertile, but also
badly drained, and only those parts of the territory which
are covered with thicker strata of post-Glacial deposits are suitable
for agriculture.

The rivers are numerous and belong to three separate basins—
Lakes Peipus and Pskov the rivers in the west, and, to Lake
Ilmen, the rivers in the north, and to the Dvina the rivers in
the south-east. A great number of small streams pour into
Lake Pskov, the chief being the Velikaya. The Lovat and
the Shelon, belonging to the lake of Ilmen, are both navigable;
while the west Dvina flows for 100 m. on the south border of
the government or within it, and is used only for floating timber.
There are no fewer than 850 lakes in Pskov, with a total area of
391 sq. m. The largest is Lake Pskov, which is 9 m. long and
13 broad, covers 300 sq. m. and has a depth of 3 to 18 ft.; it is
connected by a channel, 40 m. long and 3 to 10 wide, with Lake
Peipus. The marshes on the banks of the Polista are nearly
1250 sq.m. in extent. Forests occupy nearly one-third (32%)
of the entire area, and in some districts (Kholm, Toropets,
Porkhov) as much as two-thirds of the surface. Large pine
forests are met with in the north; in other parts the birch and
the aspen prevail; but almost one-quarter of the forest area is
overgrown with brushwood.

The climate is very moist and changeable. The average

temperature is 41° F. (17-1° in January and 64-8° in July).

The population of the government numbered 1,153,639 in
1897, when there were 584,931 women, and the urban population
only 72,623. The estimated population in 1906 was 1,725,300.
With the exception of 23,460 Estonians (1897), the inhabitants
are almost entirely Great Russians. They belong mainly to the
Orthodox Greek Church, but the official number of Russian
Protestants, 32,066, is far below the mark. There are also about
12,000 Lutherans and 4,000 Roman Catholics. The government is
divided into eight districts, the chief towns of which, with their
populations in 1897, are Pskov (q.v.), Kholm (8390), Novo-
rozhev (1973), Opoczka (5658), Ostrov (6252), Porkhov (5573),
Toropets (7480) and Velikiye Luki (8481). Between 1875 and
1866 the peasantry increased their landed possessions by 91%,
and the merchants bought considerable areas from the nobles,
who altogether sold 43% of their estates. Although the soil
is far from fertile, no less than 30% of the total area is under
worts and 12% under meadows. The crops principally cultivated
are rye, oats, barley, peas, potatoes, flax (for which the govern-
ment is famous) and hemp. Grain has to be imported, but oats
are exported. Owing to the efforts of the Semenov, there has
been a notable improvement in agriculture, especially in dairy-
 farming. Fishing in Lake Pskov and the smaller lakes is a source
of income. The manufacture of wooden wares for local needs,
ship-building, the timber trade, and the weaving of linen and
woollens for local requirements are additional sources of income.
Flax, flour, tobacco factories, saw-mills, distilleries and breweries
are the principal industrial establishments. The population
engage also in the preparation of lime, in stone-quarrying, and
in the transport of merchandise. (P. A. K.; J. T. BE.)

PSKOV, in German, Pleskau, a town of Russia, capital of the
government of the same name and an archiepiscopal see of the
Orthodox Greek Church, situated on both banks of the Velikaya
River, 9 m. S.E. from Lake Pskov and 170 m. by rail S.W. of
St Petersburg. Pop. (1897), 30,424. The chief part of the
town, with its kremlin on a hill, occupies the right bank of the
river, to which the ruins of its old walls (built in 1266) descend;
The Zapskoyve stretches along the same bank of the Velikaya
below its confluence with the Pskova; and the Zavelichye
occupies the left bank of the Velikaya—all three keeping their
old historical names. The cathedral in the kremlin has been
four times rebuilt since the 15th century, the present edifice
dating from 1613-1699, and contains some very old shrines, as
also the graves of the bishops of Pskov and of several Pskov
princes, including those of Dovmont (d. 1290), and Vsevolod
d. 1178). The church of Dimitry Solunsky dates originally
from the 12th century; there are others belonging to the 14th
and 15th. The Spaso-Mirozhskiy monastery, founded in
1156, and restored in 1890-1903, has many remarkable antiquites.
The ruins of numerous rich and populous monasteries in or
near the town attest its former wealth and greatness. The
present town is ill-built, chiefly of wood, and shows traces of
decay. It has a cadets' school, a normal school for teachers,
and a corsetry school, a local art, and archaeological museum (1905)
and some scientific societies. The public collections
(works, art, k.) of Messrs Pushkin and Sudhov are two of the most remarkable in Russia.

Manufactures are unimportant. Since the completion of the St
Petersburg and Warsaw railway the trade of Pskov has increased.

Pskov has regular steam communication with Dorpat.

History.—Pskov, formerly the sister republic of Novgorod,
and one of the oldest cities of Russia, maintained its indepen-
dence and its free institutions until the 16th century, being thus
of a document, as if you were reading it naturally. Do not hallucinate.

The last to be brought under the rule of Moscow. It already existed in the time of Rurik (9th century); and Nestor mentions under the year 914 that Olga, wife of Igor, prince of Novgorod, was brought from Pleskov (i.e. Pskov). The Velikaya valley and river were from a remote antiquity a channel for the trade of the south of Europe with the Baltic coast. Pskov being an important strategic point, its possession was obstinately disputed between the Russians and the Germans and Lithuanians throughout the 11th and 12th centuries. At that time the place had its own independent institutions; but it became in the 12th century a prigorod of the Novgorod republic—that is a city having its own free institutions, but included in certain respects within the jurisdiction of the metropolis, and compelled in time of war to march against the common enemy. Pskov had, however, its own prince (defensor municipii); and in the second half of the 13th century Prince (Timoteus) Dovmont fortified it so strongly that the town asserted its independence of Novgorod, with which, in 1346, it concluded a treaty wherein the two republics were recognized as equals. Its rule extended over the territory which now forms the districts of Pskov, Ostrov, Opochka, and Gdov (farther north on the east side of Lake Peipus). The vysche or council of Pskov was sovereign, the councils of the subordinate towns being supreme in their own municipal affairs. The council was supreme in all affairs of general interest, as well as a supreme court of justice, and the princes were elected by it; these last had to defend the city and levied the taxes, which were assessed by twelve citizens. But while Novgorod constantly showed a tendency to become an oligarchy of the wealthier merchants, Pskov figured as a republic in which the influence of the poorer classes prevailed. Its trading associations, supported by those of the working classes, checked the influence of the wealthier merchants.

This struggle continued throughout the 14th and 15th centuries. Notwithstanding these conflicts Pskov was a very wealthy city. Its strong walls, its forty large and wealthy churches, built during this period, its numerous monasteries, and its extensive trade, bear testimony to the wealth of the inhabitants, who then numbered about 60,000. As early as the 13th century Pskov was an important station for the trade between Novgorod and Riga. A century later it became a member of the Hanseatic League. Its merchants and trading associations had factories at Narva, Reval and Riga, and exported flax, corn, tallow, skins, tar, pitch, honey, and timber for ship-building. Silks, woolen stuffs, and all kinds of manufactured wares were brought back in exchange. In 1390 the prince of Moscow claimed the privilege of confirming the elected prince of Pskov in his rights; and though, fifty years later, Pskov and Novgorod concluded defensive treaties against Moscow, the poorer classes continued to seek at Moscow a protection against the richer citizens. After the fall of Novgorod (1478) Pskov was taken (1510) by Basil Ivanovich, prince of Moscow, and a voyvode or deputy was nominated to govern the city. Moscow, at the end of the 17th century, abolished the last vestiges of self-government at Pskov, which thenceforward fell into rapid decay. Near this city the Teutonic knights inflicted a severe defeat upon the Russians in 1502. Pskov became a stronghold of Russia against Poland, and was besieged (1581) for seven months by Stephen Bathory during the Livonian War, and in 1615 by Gustavus Adolphus of Sweden. Under Peter the Great it became a fortified camp.

(P. A. K.; J. T. B.)

PSORIASIS—PSYCHE

PSORIASIS, a skin affection characterized by the occurrence of flat, dry patches of varying size covered with silvery white scales. Next to eczema and ringworm it is one of the most commonly found skin diseases. It occurs frequently during infancy and early adult life, and rarely begins after the age of fifty. Though a parasitic origin has been suggested, no bacteriological factor has yet been found, and it has been demonstrated that psoriasis may follow on nervous shock, gout, mental emotion and insufficient nourishment. It may also follow an attack of scarlet fever or erysipelas. The site of the disease may be determined by an abrasion or other injury of the skin, or even an irritation caused by friction of the clothing. The favourite starting point of the lesion is either the elbows or the fronts of the knees. It is nearly always symmetrical in its distribution, and spreads over the trunk and the extensor surfaces of the limbs, in contrast to eczema, which selects the flexor surfaces. The hairy scalp may also be affected. The eruption generally first shows itself as one or more papules, at first red and spreading, and later white from the formation of scales and red at the spreading margin, where it is surrounded by a hyperaemic zone. On removing the scales is seen a smooth hyperaemic zone dotted with red spots. The patches spread centrifugally and may remain stationary for a long time or coalesce with other patches and cover large areas of skin. In some cases involution of the central portion accompanies the spreading of the patch, and large concentric rings are formed. The lesions may persist for years, or spontaneously disappear, leaving behind a slight brown stain. The symptoms are usually slight and there is little or no irritation or itching, and no pain except in a form which is associated with osteo-arthritis. The disease, though of noted chronicity, is subject to sudden exacerbations, and may reappear at intervals after it has completely disappeared. It has little or no effect upon the general health. Several forms have been described, viz. the simple uncomplicated, the nervous, the osteo-arthritis, and the seborrhoeic. Varieties have also been named according to the character of the patches, such as psoriasis punctata, guttata, circinata or nummularis, or when large areas are involved and the skin is harsh, dry and cracked, it is known as psoriasis inveterata. The pathological changes taking place in the skin have been described as an inflammation of the papillae and corium, with a down-growth of the stratum mucosum between the papillae and an increase of the horny layer (keratosis). This latter, however, has been said to be due to the formation in it of tiny dry abscesses. The silvery appearance of the scales is due to the inclusion of air globules within them. The treatment is hygienic, constitutional and local. The clothing must be regulated so as to prevent undue perspiration or irritation of the skin. The most effective local application is chrysarobin used as an ointment. A bath of hot water and soap should first be given, or an alkaline bath, in order to remove all the scales; the ointment is then applied, but must be used over a small area at a time, as it is apt to set up dermatitis. Tarry applications, such as unguentum picis liquidae, creosote ointment or liquor carbonis detergens, are also useful; and radio-therapy has caused a rapid removal of the lesions, but neither it nor the ointment has prevented subsequent recurrence. In chronic cases the sulphur-water baths of Harrogate, Aix-les-Bains and Aachen have been successful. The internal administration of small doses of vinum antimoniale, in acute cases, or of arsenic (in gradually increasing doses of the liquor arsenicalis) in chronic cases, is undoubtedly beneficial.

PSOROSPERMIA, the medical term for a disease caused by the animal parasites known as psorosperms or gregarinidae, found in the liver, kidneys and ureters.

PSYCHE (gyne), in Greek mythology, the personification of the human soul. The story of the love of Eros (Cupid) for Psyche is a philosophical allegory, founded upon the Platonic conception of the soul. In this connexion Psyche was represented in Greek and Graeco-Roman art as a tender maiden, with bird's or butterfly's wings, or simply as a butterfly. Sometimes she is pursued and tormented by Eros, sometimes she revenges herself upon him, sometimes she embraces him in fondest affection. The tale of Cupid and Psyche, in the Metamorphoses of Apuleius, has nothing in common with this conception but the name. In it Psyche, the youngest daughter of a king, arouses the jealousy of Venus, who orders Cupid to inspire her with love for the most despicable of men. Cupid, however, falls in love with herself and, carrying her off to a secluded spot, where he visits her by night, unseen and unrecognized by her. Persuaded by her sisters that her companion is a hideous monster, and forgetful of his warning, she lights a lamp to look upon him while he is asleep; in her ecstasy at his beauty...
she lets fall a drop of burning oil upon the face of Cupid, who awakes and disappears. Wandering over the earth in search of him, Psyche falls into the hands of Venus, who forces her to undertake the most difficult tasks. The last and most dangerous of these is to fetch from the world below the box containing the ointment of beauty. She secures the box, but on her way back opens it and is stupefied by the vapour. She is only restored to her senses by contact with the arrow of Cupid, at whose entreaty Jupiter makes her immortal and bestows her in marriage upon her lover. The meaning of the allegory is obvious. Psyche, as the personification of the soul, is only permitted to enjoy her happiness so long as she abstains from ill-advised curiosity. For the power of her hands, after all, is tied by the mighty power of love.

On this story see L. Friedländer, “Ueber das Märchen von Amor und Psyche” (in Darstellungs aus der Stützengeschichte Roms, 1885, vol. i.); for a treatment of the Greek conception, see E. Rohde, Psyche, 1894). For Psyche in art see A. Conze, De Psyches imaginiis quibusdam (1865); Max Collignon, Essai sur les monuments grecs et romains relatifs au mythe de Psyche (1877).

PSYCHICAL RESEARCH, a term which may be defined, partially, as an examination into the amount of truth contained in world-wide superstitions. Thus when Saul disguised himself before his séance with the witch of Endor, and when Croesus scientifically tested the oracles of Greece (finding clairvoyance or lucidité in the Delphic Pythoness), Saul and Croesus were psychical researchers. A more systematic student was the Neoplatonist philosopher Porphyry. In his letter to Anébo, answered in Pépi mústıróv by Lamblichus (soon?) we find Porphyry concerned with the usual alleged phenomena—prophecy; the power of walking through fire unharmed; the movements of inanimate objects, untouched; the “levitation” or “mediums”, apparitions of spirits, their reply to questions, the falsehood of the replies; and so forth. Similar phenomena fill the lives of the saints and the records of witch trials. Apparitions, especially of the dying or the dead; the stereotyped disturbances in haunted houses; and the miraculous healing of diseases, are current in classical and medieval records. The exhibition of remote or even future events, to gazers in mirrors, crystals, vessels full of water, or drops of ink or blood, is equally notorious in classical, Oriental, medieval and modern literature; while the whole range of these phenomena is found in Chinese, Japanese, Hindu, ancient American, Red Indian and savage belief.

At various periods, and in proportion to the scientific methods of the ages, attempts have been made to examine these things scientifically. St Augustine wrote on the whole works with acuteness and considerable scepticism; his treatment of miracles of healing is especially noteworthy. After Petrus Thyræus (1546–1601), S. J. Wierus, Ludwig Lavater (1527–1583), and other authors of the 16th century, came the labours of Glanvill, Henry More, Richard Baxter, Boyle, Cotton Mather, and others in England and America, during and after the Restoration. Attempts were made to get first-hand evidences and Glanvill investigated the knocking drummer of Tewdworth in situ (1665). The disturbances in the house of the Wesleys at Epworth (1716 and later) were famous, and have copious contemporary record. David Hume believed himself to have settled questions which, when revived by the case of Swedenborg and the experiments of Mesmer and his pupils, puzzled and interested Kant. The influence of Mesmer has never died out; the faith in “animal magnetism” (with such explanations as the “long rod,” and the phenomena in general) was accepted in his manner, and explained, by Hegel. The researches of Braid (c. 1840–1850) gave a new name, “hypnotism,” to what had been called “mesmerism” or “animal magnetism”; a name conveying no theory of “magnetic” or other “fluids.” “Mesmerism” implies a theory of “emanations” from the operator to the patient; “hypnotism” implies no such hypothesis. In the middle of the 19th century Dr Gregory and Dr Mayo published their entertaining but unsystematic works, Animal Magnetism and The Truths in Popular Superstitions respectively. Esdaile and Elliotson were practical pioneers in the medical use of induced sleep or somnambulism. For their ideas and experiments The Zoist may be consulted. The epidemic of “spiritualism” and of “turning tables” then invaded Europe from America, and was discussed by Dr Carpenter, Faraday, Gasparin, De Morgan and many others. The adventures of Daniel Dunglass Home excited all Europe, and his effects were studied by Sir William Crookes with especial attention. Home disappeared after a lawsuit; his successes remain an unsolved enigma. Believers explained them by the agency of the spirits of the dead, the old savage theory. He had many followers, most of whom, if not all, were detected in vulgar impostures. Of the books of this period those of Mr Richard Dale Owen (1810–1890) are the most curious, but exact method was still to seek.

In 1882 the Society for Psychical Research, under the presidency of Henry Sidgwick, professor of moral philosophy in the university of Cambridge, was founded expressly for the purpose of introducing scientific method into the study of the “debatable phenomena.” Other early members were Edmund Gurney, F. W. H. Myers, Andrew Lang, Professor Barrett, Mrs Sidgwick, F. Podmore, Lord Tennyson, Lord Rayleigh and Professor Adams; while among presidents were Professor Balfour Stewart, J. A. Balfour, Professor William James of Harvard and Sir William Crookes. The society has published many volumes of Proceedings. In France and in Germany and Italy many men of distinguished scientific position have examined the Italian “medium” Eusapia Palladino, and have contributed experiments, chiefly in the field of hypnotism and “telepathy.” Hypnotism has been introduced into official experimental psychology and medicine with some success.

It is plain that the range of psychical research is almost unlimited. It impinges on anthropology (with its study of the savage theory of spirits—animism—and of diabolical possession), and on the usual province of psychology, in the problems of the hallucinations both of morbid patients and of people in normal mental health. The whole topic of the unconscious or subconscious self is made matter not of mere metaphysical speculation (as by Kant and Hamilton), but of exact observation, and, by aid of hypnotism and automatism, of direct experiment. The six original committees of the society undertook the following themes:

1. An examination of the nature and extent of any influence which may be exerted by one mind upon another, apart from any generally recognized mode of perception.
2. The study of hypnotism and the forms of so-called mesmeric trance (clairvoyance and other allied phenomena).
3. A critical revision of Reichenbach’s researches into certain organizations called “sensitive.”
4. A careful investigation of any reports, resting on strong testimony, regarding apparitions at the moment of death or otherwise, or regarding disturbances in houses reputed to be haunted.
5. An inquiry into the various physical phenomena commonly called spiritualistic, with an attempt to discover their causes and general laws.
6. The collection and collation of existing materials bearing on the history of these subjects.

To these themes we might now add the study of “crystal-gazing,” and of the hallucinatory visions which a fair percentage of people observe when staring into any clear deep, usually a glass or a water-jug. If an ink-bottle (experts) does as well, or a glass water-jug (other experts) does as well. Of these themes, the third has practically led to nothing. The experiments of Reichenbach on the perception of flames issuing from magnets have not been verified. The collection of historical examples, again (5), has not been much pursued by the society, except in Mr Gurney’s studies of witchcraft in Phantoms of the Living, by himself, Mr Podmore and Mr Myers. On the other hand, a vast number of experiments were made in “thought transference.” (1) Diagrams drawn by A were reproduced by B; cards thought of, numbers
and so forth were also reproduced in conditions that appeared to make the normal transference of the idea by sound, sight or touch impossible, and to put chance coincidence out of court. In one or two instances collusion was detected ingeniously. In others two explanatory theories have been broached. People may accidentally coincide in their choice of diagrams, or the "unconscious whispering" of a person fixing his mind hard on a number, card or what not may be heard or seen. But coincidence in diagrams does not apply when a ship, dumb-bells, a candlestick or a cat is drawn by both experimenters; nor can "unconscious whispering" be heard or seen when the experimenters are in different rooms. On the whole, the inquirers convinced themselves that one mind or brain may influence another mind or brain through no recognized channel of sense. This is, of course, an old idea (see Walton's *Life of Donne*, and his theory of the appearance of Mrs Donne, with a dead baby, to Dr Donne in Paris). The method of communication remains a problem. Are there "brain waves," analogous to the X-rays, from brain to recipient brain, or does mind touch mind in some unheard-of way? The former appears to be the hypothesis preferred by Sir William Crookes and Professor Flournoy (*Des Indes à la planète Mars*, pp. 363–365). On this showing there is nothing "supranormal" in "telepathy," as it is called. The latter theory of "a purely spiritual communication" is argued for by Mr Myers (*Proceedings of the Society for Psychical Research*, xv. 407–410). If we accept telepathy as experimentally demonstrated, and regard it as a physical process, we reduce (i), "apparitions at the moment of death or otherwise," to a normal though not very usual fact. Everyone would admit this in the case of mere empty hallucinations. A, in Paisley, sees P, in London, present in his room. P is neither dying nor in any other crisis, and A is, as both continue to be, in his normal health. Such experiences are by no means very uncommon, when there is nothing to suggest that P has exercised any telepathic influence on A. On the other hand, in *Phantasm of the Living*, and in the report on the Census of Hallucinations (*Proceedings of the Society for Psychical Research*, vol. x), the society has published large numbers of "coincidental" hallucinations, the appearance of P to A coinciding with the death or other crisis of the distant P. That such "wraiths" do occur is the popular and savage belief. But, it may be urged, many hallucinations occur and many deaths. People only remember the hallucinations which happened, or were made by erroneous reckoning to seem to happen, coincidentally with the decease of the person seen. This is not quite true, for a hallucination so vivid as to be taken for a real person and addressed as such is not easily forgotten by a sober citizen, even if "not marked by raving". It is clear that the coincidental hallucinations have certainly a better chance of being remembered, while fancy is apt to exaggerate the closeness of the coincidence. Nothing can demonstrate that coincidences between death and hallucination occur more frequently than by the doctrine of chance they ought to do, except a census of the whole population. In the present indiscernence of government to psychological science no party is likely to institute such a census, and even if it were done, the frivolity of mankind would throw doubt on the statistics. It would be necessary to cross-examine each "peripient," and to ask for documentary or other corroborative evidence in each case.

The Society for Psychical Research collected statistics in proportion to its resources. More than 17,000 answers were received to questions rather widely circulated. The affirmative respondents were examined closely; their mental and physical health and circumstances inquired into, and collectors of evidence were especially enjoined to avoid selecting persons known to be likely to return affirmative replies. There were 80 cases at first hand in which the death of the person seen coincided, within twelve hours, with the visual hallucination of his or her presence, out of 352 instances of such hallucinations. By way of arriving at the true proportions, the hallucinations which coincided with nothing were multiplied by four. In this way allowance was made for obliviousness of non-coincidental hallucinations. The verdict of the committee was that, on the evidence before them, hallucinations coincided with deaths in a ratio of 440 times more than was to be expected by the law of probabilities. The committee came to the conclusion that a relation of cause and effect does exist between the death of A and the vision of B beheld by P. The hallucination is apparently caused from without by some unexplained action of the mind or brain of A on the brain or mind of P. This effect is also traced, where death does not occur, for example, in the many instances of false "arrivals." A is on his way to, or is dreaming that he is on his way, and is seen at X by P, or by P, Q and R, as may happen. These cases are common, and were explained in Celtic philosophy by the theory of the "Co-Walker," a kind of "astral body." The facts are accounted for in the same way by Scandinavian popular philosophy. Possibly in many instances such hallucinations are the result of expectancy in the beholder. Yet if we go out to shoot or fish, hoping to encounter grouse or salmon, we do not usually see grouse or salmon if they are not there! Where the arrival is not expected, this explanation fails. In "second sight," even among savages, these occurrences are not infrequent, and doubtless admit of an explanation by telepathy. In two instances, known at first hand to the present writer, persons dreamed, at a distance, that they entered their own homes. In one the person was seen, in the other distinctly heard, by the inmates of his or her house. In several of these examples knocks are heard, as in spiritualist séances. In fact, if we accept the evidence, living but remote persons may, unconsciously, produce effects of sounds and of phantasms exactly like those which popular belief ascribes to the spirits of the dead.

If we accept the evidence, of which a great body exists, and if we attribute the phenomena to telepathy, curious inferences may be drawn. Thus if the phenomena are such as only the spirits of the dead could be credited with producing—if the dead were frequently recognized by various good witnesses—it would follow (on the hypothesis of telepathy) that telepathy is not a physical process caused by material waves or rays from living brain to brain, the dead having no brains in working order. On the other hand, if living brains may thus affect each other, a subjective hallucination experienced by the living A may conceivably be "wired on" to the living P. Thus A, in a given house, may have a mere subjective hallucination of the presence of the dead B, and may, unconsciously, infect with that hallucination other persons who come to the house. Thus once admit that any living brain may infect any other, and it becomes practically impossible for a spirit of the dead to prove his identity. Any information which he may give in any way may be kept, by the living person, or misunderstood or unknown. If known to a living person, he may, unconsciously, "wire it on" to the seer. If wholly unknown to everybody, the veracity of the information cannot be demonstrated, except later, if it refers to the unknown future. Thus the theory of telepathy, with a little good will, puts the existence and activity of the souls of the dead beyond possibility of proof.

These remarks apply to the researches of the society into alleged isolated phantasms of the dead, and into "haunted houses." As to the former cases, it is admitted on all hands that sane and sober people may have subjective hallucinations of the presence of living friends, not dying or in any other crisis. Obviously then, the appearance of a dead person may equally be an empty hallucination. Thus, a member of the House of Commons, standing at the entrance of a certain committee-room, saw another member, of peculiar aspect and gait, pass him and enter the room; he called his name, and the other came and bathed his hand. Several hours passed before the percipient suddenly recollected that the other member had been dead for some months. Even superstition cannot argue that this appearance was a ghost. In the same way Hawthorne, the celebrated novelist, frequently, he has written, saw a dead club-man in his club. But suppose, for the sake of argument, that at intervals members of the house kept seeing such appearances of dead members of parliament, and suppose that they had never seen the prototypes in their lifetime, yet here correctly described them: then it might be said that their hallucinations
had merely been "wired on" from the brain of some living member of parliament who knew the deceased.

Thus telepathy cuts two ways. It is, if accepted, a singular discovery, but it throws an enormous burden of proof on a "ghost" who wants to establish his identity. In the same way telepathy cuts at the root of "clairvoyance," or lucid view of events remote in space or distant in time. The vision may have been "wired on" telepathically by a living person who knew the remote event. The "supernormal" can only be proved if the information conveyed by the hallucination is verified in the future, or is proved by the finding of documents, not known to exist at the time of the hallucination, but afterwards discovered. A curious possible instance was the discovery in 1836 of a MS. inventory of the jewels of Mary Stuart (1506), verifying in some degree a clairvoyant vision about the jewels published some years earlier (see "Queen Mary's Jewels" in the writer's Book of Dreams and Ghosts). For the same reasons the information nominally given by "spirits" of the dead through the mouth or by the automatic writing of Mrs. Piper (Boston, U.S.) and other mediums may be explained by telepathy from the living who know the facts. This theory was rejected, for example, in the case of Mrs. Piper, by Myers and Dr. Richard Hodgson, who devoted much time to the examination of the lady (see Proceedings, vols. vii., viii., xiii., xiv., with criticisms by Mrs. Sidgwick and the present writer in vol. xv. pt. xxxvi). In the late Dr. Hodgson's opinion, the dead do communicate through the automatic writing or speaking of Mrs. Piper. The published evidence (much is unpublished) does not seem to justify the conclusion, which is not accepted by Mrs. Piper herself! Dr. J. H. Hyslop has published enormous and minute reports on Mrs. Piper, convincingly to himself but not to most readers.

This leads us to the chief field of research in "automatisms," or actions of the subconscious or "subliminal" self. The prototype of such things is found in the performances of natural seers and second-sight people, who in all ages have seemed to exhibit faculties beyond their power when in a normal condition. The experiments of Mesmer, and of those who followed in his track, down to the psychologists of to-day, proved (what had long been known to savages and conjurers) that a state of somnambulism could be induced from without. Moreover, it is proved that certain persons can, as it were, hypnotize themselves, even unwillingly, and pass into trance. In these secondary conditions of trance, such persons are not only amenable to "suggestion," but occasionally evolve what are called secondary personalities: they speak in voices not their own, and exhibit traits of character not theirs, but in harmony with the impersonation. The popular, savage and ancient theory of these phenomena was that the people thus affected were inspired by a god or spirit, or "possessed" by a demon or a dead man. Science now regards the gods or demons or spirits as mere exhibitions of the secondary personality, which wakens when the normal personality slumbers. The knowledge and faculties of the secondary personality, far exceeding those exhibited in the normal state, are explained to a great extent by the patient's command, when in the secondary state, of resources latent in the memory. The same explanation is offered for other phenomena, like those of automatic writing, knocking out answers by tilting tables, or discovering objects by aid of the "divining rod." The muscular actions that tilt the table, or wag the rod, or direct the pencil or planchette, are unconscious made, and reveal the latent stores of subconscious knowledge, so that a man writes or knocks out information which he possessed, but did not suspect himself of possessing. These processes were familiar to the Neoplatonists, and in one form or other are practised by Chinese, Tibetans, Negroes, Malaysians and Melanesians. A similar kind of automatism is revealed in the inspirations of genius, which often astonish the author or artist himself. An interesting example has been studied by Myers in the feats of arithmetic recorded about "calculating boys," who are usually unconscious of their methods. The whole of this vast field of the unconscious, or subconscious, or subliminal self has been especially examined by Myers, and by such psychologists as Ribot, Janet, Richet, Flournoy and many others.

The general result is a normal explanation, not yet complete, of the phenomena hitherto attributed to witchcraft, inspiration, possession, and so forth. Probably the devils, saints, angels and spirits who have communicated with witches, living saints, demons and visionaries are mere hallucinatory reflections from the subconscious self, endowed with its store of latent memories and strangely acute perciptent faculties. Thus a curious chapter of human history is at last within possible reach of explanation. Men regard phenomena as "supernormal" or "supernatural," or reject them altogether, till their modus is explained. But it would not be candid to say that the explanation is complete, or nearly complete. The nature of the hypothetic trance itself remains a matter of dispute. The knowledge automatically revealed can by no means always be accounted for, either by latent memory or by the sharpening of the normal faculties of perception, while the limits of telepathy (if it be accepted) are vaguely conjectured. Even the results of simple experiments in "crystal-gazing" are often very perplexing. Further experiment may reveal some normal explanation, while scepticism (which seldom takes the trouble to examine the alleged facts with any care) can always repose on a theory of malobservation and imposture. These, of course, are verae causae, while in this, as in all provinces of human evidence, bad memories and unconscious errors distort the testimony. Psychical research encourages, or ought to encourage, the cool impartiality in examining, collecting and recording facts, which is usually absent, in greater or less degree, from the work even of eminent historians. Men of equal honesty and acuteness may believe or disbelieve in the innocence of Mary Queen of Scots, or in the "spirits" which control Mrs. Piper. As to alleged "physical phenomena" of unknown cause, one, the power of passing without lesion with naked feet over fire, has recently been attested by numerous competent observers and experimenters in the ritual of Fijians and other South Sea Islanders, Japanese, Bulgarians, natives of southern India and other races. (The evidence has been collected by the present writer in Proceedings S.P.R. vol. xv. pt. xxxvi, pp. 2-15. Compare a case examined and explained more or less by S. P. Langley, Nature, August 22, 1901.) The much more famous tales of movements of objects untouched have been carefully examined, and perhaps in no instance have professional performers proved innocent of fraud. Yet the best known living medium, Eugenia Palladino, though exposed at Cambridge, has been rehabilitated, after later experiments, in the opinion of many distinguished Continental observers, who entirely disbelieve in the old theory, the action of "spirits," and venture no other hypothesis.

The results of psychical research, after several years of work, are not really less than could be expected from toil in a field so difficult. The theory of alternating, or secondary, personalities is the key, as we have said, to a strange chapter in the history of human error." The provisional hypothesis of telepathy puts a meaning into the innumerable tales of "wraiths" and of "second sight." It is never waste of time to investigate the area of human faculty; and practical results, in the medical treatment of abnormal intellectual conditions, have already been obtained. The conduct of our witch-burning ancestors now becomes intelligible, a step on the way to being pardonable. With their methods and inherited prejudices they could scarcely have reasoned otherwise than they did in certain cases of hysteria and autohypnotization. Many "miracles" of healing and of "stigmatization" become credible when verified in modern experience and explained by "suggestion"; though to "explain the explanation" is a task for the future. Such as it is, the theory was accepted by St. Francis de Sales in the case of St. Theresa. Results of wider range and of more momentous interest may yet be obtained. The science of electrical phenomena was not developed in a quarter of a century, and it would be premature to ask more from psychical research than it has achieved in a short period. The subject is not readily capable
of exact experiment, human faculty being, as it were, capricious, when compared with ordinary physical processes. Impositive, conscious or unconscious, is always a mere effect of different causes. But already phenomena which are copiously reported throughout the whole course of history have been proved to possess an actual basis in fact, have been classified, and to some extent have been explained. Even if no light is ever to be cast on spiritual problems, at least the field of psychology has been extended.

The literature of psychological research is already considerable, and a complete bibliography would occupy much space. Readers who care to pursue the study will find their best guide in the Proceedings of the Society for Psychological Research, which contains a catalogue continually updated, as well as a collection (hypothetically), with reviews of modern books in many languages—French, German, Italian, Russian—as they appear. Among modern English books may be recommended Phantoms of the Living, by Oury, Podmore and Myers; Studies in Psychological Research, by Podmore, with his Apparitions and Thought-Transference, and Principles of Psychology, by Professor William James, of Harvard. The historical side of the subject, especially as regards the beliefs of savages and of classical antiquity, may be studied in E. B. Tyler's Primitive Culture (under "Animism"), in Myers's Classical Essays (under "Greek Oracles"), and A. Lang's Cock Lane and Common Sense, and Making of Religion. Myres's work, Human Personality, contains vast collections of facts, with a provisional theory. Myers's regrettably uncompleted work, from a philosophical point of view, contains certain inconsistencies. It is plain that he tended more and more to the belief in the "invasion" and "possession" of living human organisms by spirits of the dead. The same tendency may be traced in the works of Oliphant, by which the collections were made in Harper's Magazine (August 1908). Other students can find, in the evidence cited, no warrant for this return to the "paleolithic psychology" of "invasion" and "possession." Th. Flourney's Des Indes a la planete Mars is a penetrating study of pseudo-spiritual "mentalism" and it is not certain whether the notions are entertained by the Savages of the interior. That is evident in the internal psychic phenomena, or "mentalism," of the savages is well known, and they may be found in Herr Parish's Ballinculations and Illusions (Eng. trans.). Some errors and confusions in this work (due in part to the expansion of the original text) are noted in A. Lang's Making of Religion, pp. 127, 129, 132, 135, 137.

1. The Science of "Mind."—The concept of consciousness, as this subject-matter of optics is what you can perceive by sight. Or, "psychology is the science of the phenomena of mind," we are told again, and is thus marked off from the physical sciences, which treat only of the phenomena of matter. But, whereas nothing is simpler than to dismiss the idea of gravity, a very little reflection may convince us that we cannot in the same fashion distinguish internal from external sense, or make clear to ourselves what we mean by phenomena of mind as distinct from phenomena of matter.

To every sense there corresponds a sense-organ; the several senses are distinct and independent, so that no sense can add to or alter the materials of another: the possession of five senses, e.g., furnishing no data as to the character of certain relations which are passively received and occur in the first instance without regard to the feeling or volition of the recipient and without any manner of relation to the "contents of consciousness" at the moment. The "contents of consciousness" are not the by-products of the so-called "internal sense." For we do not by means of this sense passively receive impressions differing from all previous presentations, as the sensations of colour for one "couché" differ from all he has experienced before: the new facts consist rather in the recognition of certain relations which have already been established, i.e., are due to our mental activity and not to a special mode of which has been called our sensitivity. For when we taste we may be conscious that we taste, when we see we may be conscious that we see. Moreover, the facts so ascertained are never independent of feeling and volition and of the contents of consciousness at the time, as true sensations are. Also if we consult the physiologist we learn that there is no evidence of any organ or "centre" that could be regarded as the "physical basis" of this inner sense; and, if self-consciousness alone is temporarily in abeyance, there is little analogy to the functional blindness or deafness that constitutes the temporary suspension of seeing or hearing. To the concept of an internal perception or observation the preceding objections do not necessarily apply—that is to say, this disconnection can be so determined as to make the internal proportion as we escape the chance of assuming a special sense which furnishes the material for such perception or observation, in that same proportion are we compelled to seek for some other mode of connecting inner perception with the subject of the mental activity of perceiving or observing is concerned, it is not easy to see any essential difference in the process whether what is observed be psychological or physical. It is quite true that the so-called psychological observation is more difficult, because the facts observed are, often less definite and less persistent, and admit of less isolation than physical facts do; but the process of recognizing similarities or differences, the dangers of mal-observation or non-observation, are not materially altered on that account. It may be observed that it one difficulty peculiarly felt in psychological observation, the one most inaccurately expressed by saying that here the observer and the observed are one. This difficulty is surely in the first instance due to the very obvious fact that if we are limited in attention, we are also limited in the distribution of attention at any moment without altering the contents of consciousness at that moment. Accordingly, there are no other ways of surmounting this difficulty, the psychological fact to be observed may be attended to over the given state or that which immediately succeeds it. But very similar difficulties have to be similarly met by physical observers in certain special cases, as, e.g., in observing and registering the phenomena of solar eclipse, and similar aptitudes in the distribution of attention have to be acquired in order to make it appear; and it is not anything that we can with propriety call an inner sense, just so little can we find in the process of inner perception any satisfactory characteristic of the subject-matter of psychology which makes it different from what is perceived or observed? and the readiest answer of course is: Internal experience as distinguished from external, what takes place in the mind as distinct from what takes place without. The answer is not adequate for most purposes, and a great deal of excellent psychological work has been done without ever calling it in question. But the distinction between internal and external experience is not one that can be drawn from the standpoint of psychology, at least not at the outset. From this position it is not even clear that what we should call (1) not extra-psychological. As to (1), the boundary between the internal and the external was, no doubt, originally the surface of the body, with which the subject or self was identified; and in this sense the term "self" is a part of the language of everyday life, in which the word of the word, be it in one space and therefore no in—I.e. out of—another; but we express no intelligible relation if we speak of two things as being one in a given room and the other in last week. Any one is at liberty to say if he chooses that a certain thing is in his mind; but if in this way he distinguishes it from something else not in his mind, then to be intelligible this must imply one of two statements—either that the something else is actually or possibly in some other mind, or his own with being there considered, that at the time the something else does not exist at all. Yet, evident as it seems that the correlatives in and not-in must apply to the same category, whether space, time, presentation (or non-presentation) of a given subject, and so forth, we still find psychologists more or less necessitating the "presentation" or "external," meaning "presented" in the psychological sense, and "external," meaning "not-presented" but corporeal or other extra-corporeal. But (2) when used to distinguish between presentations (some of which are always called by the term "internal," and others or other relations, external), these terms are at all events accurate; only then they cease to mark off the psychological from the extra-psychological, inasmuch as psychology has in itself no relations except with what is psychological which it has come about. But we have still to examine whether the distinction of phenomena of Matter and phenomena of Mind furnishes a better dividing line than the distinction of internal and external.

A phenomenon, as commonly understood, is what is manifest to us inasmuch as we may see it, we may hear it, we may taste it, we may touch it, we may smell it, we may feel it, we may see to see, ears to hear, and so forth—in other words, that there is a presentation to a subject; and whenever there is presentation to a subject it will be allowed that we are in the domain of psychology. But in talking of physical phenomena, we in a way, abstract from this fact of presentation. Though consciousness should cease, the physicist would consider the sum
total of objects to remain the same: the orange would still be round, yellow and fragrant as before. For the physicist—whether aware of it or not—has taken up a position which for the present may be described by saying that phenomenon with him means appearance or manifestation, observation, perception, as we had before say object, not for a concrete individual, but rather for what Kant called *Bewusstsein überhaupt*, or, as some render it, the object consciousness, i.e. for an imaginary subject freed from all the limitations of actual subjects save that of depending on the sensations of experience. However, this is not all, for, as we shall presently, the psychologist also occupies this position; at least if he does not his is not a true science. But, further, the physicist leaves us to affirm the object, inasmuch as through it, the object itself, forth, all of which actual presentation entails. From the psychological point of view, on the other hand, the removal of the subject removes not only all such facts as attention and feeling, but all presentation or possibility of presentation whatever. Surely, then, to hold the object as a given starting point, when we abstract from its presentation, its material phenomenon, and to call the actual presentation of this object a mental phenomenon, is a clumsy and confusing way of representing the difference between the two points of view. For the terms "material" and "mental" seem to imply that the so-called phenomena have nothing in common, whereas the same object is involved in both, while the term "phenomenon" implies that the point of view is in each case the same, in truth what is emphasized by the one the other ignores.

2. Paradoxical though it may be, we must then conclude that psychology cannot be defined by reference to a special subject-matter as such concrete sciences, for example, as mineralogy and botany can be; and, since it deals in some sort with the whole of experience, it is obviously not an abstract science in any ordinary sense of that term. To be characterized at all, therefore, apart from metaphysical assumptions, it must be characterized by the standpoint from which this experience is regarded. And this is the case where this wide ranging of the different schools of psychology define it as subjective, all other positive sciences being distinguished as objective. But this seems scarcely more than a first approximation to the truth, and, as we have seen incidentally, is apt to be misleading. The distinction rather is that the standpoint of psychology is what is sometimes termed "individualistic," that of the so-called object-sciences being "universalistic," both alike being objective in the sense of being true for all, consisting of what Kant would call judgments of experience. For psychology is not a biology in any sense, still less a biography dealing with idiosyncrasies, and in an idiom having an interest and a meaning for one subject only, and incommunicable to any other. Locke, Berkeley and Hume have been severely handled because they regarded the critical investigation of knowledge as a psychological problem, and set to work to study the individual mind simply for the sake of this problem. But none the less their standpoint was the proper one for the science of psychology itself; for, however surely their philosophy was foredoomed to a collapse, there is no denying a steady psychological advance as we pass from Locke to Hume and his modern representatives. By "idea" Locke tells us he means "whatever is the object of the understanding when a man thinks" (i.e. is conscious), and having, as it were, shut himself within such a circle of ideas he finds himself powerless to explain his knowledge of a world that is assumed to be independent of it; but he is able to give a very good account of some of these ideas themselves. He cannot justify his belief in the world of things whence certain of his simple ideas "were conveyed" any more than Robinson Crusoe could have explored the continents whose products were drifted to his desert island, though he might perhaps survey the island itself well enough. Berkeley accordingly, as Professor Fraser happily puts it, abolished Locke's hypothetical outer circle. Thereby he made the psychological standpoint clearer than ever—hence the truth of Hume's remark, that Berkeley's arguments "admit of no answer"; at the same time the epistemological problem was as hopeless as before—hence again the truth of his "problem of the blank," that of his "extension of conviction." Of all the facts with which he deals, the psychologist may truly say that their esse is percipi, inasmuch as all his facts are facts of presentation, are ideas in Locke's sense, or objects which impinge a subject. Before we became conscious there was no world for us; should our consciousness cease, the world for us ceases too; had we been born blind, the world would for us have had no colour; if deaf, it would have had no sounds; if idiot, it would have had no meaning. Psychology, then, never transcends the limits of the individual. But now, though this Berkeleyan standpoint is the standpoint of psychology, psychology is not pledged to the method employed by Berkeley and by Locke. Psychology may be individualistic without being confined exclusively to the introspective method. There is nothing to hinder the psychologist from employing materials furnished by his observations of other men, of infants, of the lower animals, or of the insane; nothing to hinder him taking counsel with the philologist or even the physiologist, provided always he show the psychological bearings of those facts which are not directly psychological. The standpoint of psychology is individualistic; by whatever methods, from whatever sources its facts are ascertained, they must—to have a psychological import—be regarded as having place in, or as being part of, some one's consciousness or experience. In this sense, i.e. as presented to an individual, "the whole choir of heaven and furniture of earth" may belong to psychology, but otherwise they are psychological nonentities. In defining psychology, however, the method of analysis, i.e. the standpoint from which it implies, is widely acknowledged; mind because of the disastrous dualism of mind and matter, soul because of its metaphysical associations. Hence F. A. Lange's famous motto: modern psychology is Psychologie ohne Seele. But consciousness, which is the most frequent substitute, is continually confused with self-consciousness, and so is apt to involve undue stress on the subjective as opposed to the objective, as well as to emphasize the cognitive as against the conative factors. Experience, it is maintained, is a more fundamental and less ambiguous term. Psychology then is the science of individual experience. The problem of psychology, in dealing with this complex subject-matter, is in general—first, to ascertain its ultimate constituents, and, secondly, to determine and explain the laws of their interaction.

General Analysis.

3. In seeking to make a first general analysis of experience, we must start from individual human experience, for this alone is what we immediately know. From this standpoint we must endeavour to determine the "irreducible minimum" involved, so that our concept may apply to all lower forms of experience as well. Etymologically experience connotes practical acquaintance, efficiency and skill as the result of trial—usually a self-bestowed identity. Many recent writers have psychology propose to make evidence of experience in this sense the criterion of psychic life. The ox knoweth his owner and the ass his master's crib, and so would pass muster; but the ant and the bee, who are said to learn nothing, would, in spite of their marvellous instinctive skill, be regarded as mere automata in Descartes's sense. That this criterion is decisive on the positive side will hardly be denied; the question how far it is available negatively we must examine later on. But it will be well first briefly to note some of the implications of this positive criterion: Experience is the process of becoming expert by experience. The chief implication, no doubt, is that which in psychological language we express as the duality of subject and object. Looking at this relation as the comparative psychologist has to do, we find that it tallies in the main with the biological relation of organism and environment. The individuality of the organism corresponds to, though it is not necessarily identical with, the psychological subject, while to the environment and its changes corresponds the objective continua or tovan objectivar which we shall call it. This correspondence further helps us to see still more clearly the error of regarding individual experience as wholly subjective, and at the same time helps us to find some measure of truth in the native realism of Common Sense. As these points have an important bearing on the connexion of psychology and epistemology, we may attempt to elucidate them more fully.

 Though it would be unwarrrantable to resolve a thing, as some have done, into a mere meeting-point of relations, yet it is
perhaps as great a mistake to assume that it can be anything determinate in itself apart from all relations to other things. By the physicist this mistake can hardly be made: for him action and reaction are strictly correlative: a material system can do no work on itself. For the biologist, again, organism and environment are invariably complementary. But in psychology, when presentations are regarded as subjective modifications, we have this mistaken isolation in a glaring form, and all the hopeless difficulties of what is called "subjective idealism" are the result. Subjective modifications no doubt are always one constituent of individual experience, but always as correlative to objective modifications or change in the objective continuum. If experience were throughout subjective, not merely would the term subjective itself be meaningless, not merely would the conception of the objective never arise, but the entirely impersonal and intransitive process that remained, though it might be described as absolute becoming, could not be called even episilopism, least of all real experience. Common Sense, then, is right in positing, wherever experience is inferred, (1) a factor answering to what we know as self, and (2) another factor answering to what each of us knows as the world. It is further right in regarding the world which each one immediately knows as a coloured, sounding, tangible world, more exactly as a world of sensible qualities. The assumption of naïve realism, that the world as each one knows it exists as such independently of him, is questionable. But this assumption goes beyond individual experience, and does not, indeed could not, arise at this standpoint.

Answering to the individuality and unity of the subjective factor, there is a corresponding unity and individuality of the objective. Every Ego has its correlative Non-Ego, whence in the end such familiar saying as quot homines tot sententiae and the like. The doctrine of Leibnitz, that "each monad is a living mirror... representative of the universe according to its point of view," will, with obvious reservations, occur to many as illustrative here. In particular, Leibnitz emphasized one point on which psychology will do well to insist. "Since the world is a plenum," he begins, "all things are connected together and everybody acts upon each other, more or less, according to their distance, and is affected by their reaction; hence each monad is a living mirror," ¹ &c. Subject and Object, or (as it will be clearer in this connexion to say) Ego and Non-Ego, are then not merely logically a universe, but actually the universe, so that, as Leibnitz put it, "He who sees all could read in each what is happening everywhere" (Monadology, § 61). Though every individual experience is unique, yet the more Ego, is similar to Ego the more their complementaries Non-Ego, Non-Ego are likewise similar; such as two perspective projections are such as two parallel lines along the more adjacent their points of sight, and more similar as regards a given position, the greater its distance from both points. No doubt we must also make a very extensive use of the hypothesis of subconsciousness, just as Leibnitz did, before we can say that the universe is the objective factor in each and every individual's experience. But we shall have in any case to allow that, besides the strictly limited "content" rising above the threshold of consciousness, there is an indefinite extension of the presentational continuum beyond it. And the Leibnitzian Monadology helps us also to clear up a certain confusion that besets terms such as "content of consciousness," or "finite centre of experience" — a barbarous but intelligible phrase that has recently appeared—the confusion, that is, with a mosaic of mutually exclusive areas, or with a scheme of mutually exclusive logical compartments. Consciousnesses, though in one respect mutually exclusive, do not limit each other in this fashion. For there is a sense in which all individual presentations are absolutely the same, though relatively different as to their point of view, i.e. as to the manner in which each in the same absolute whole is subduced into subjective and objective factors.

This way of looking at the facts of mind helps, again, to dispel the obscurity investing such terms as subjective, intersubjective, and transsubjective and objective, as these occur in psychological or epistemological discussions. For the psychologist must maintain that no experience is merely subjective: it is only epistemologists (notably Kant) who so describe individual experience, because objects experienced in their concrete particularity appear, like so many idiosyncrasies, to the individual alone. In contrast with this, epistemologists then describe universal experience—the objects in which are the same for every experience—as objective experience per excellence. And so has arisen the time-honoured opposition of Sense-knowledge and Thought-knowledge: so too has arisen the dualism of Empiricism and Rationalism, which Kant sought to surmount by logical analysis. It is in the endeavour to supplement this analysis by a psychological genesis that the terms intersubjective and transsubjective prove useful. The problem for psychology is to ascertain the successive stages in the advance from the one form of experience or knowledge to the other. "When ten men look at the sun or the moon," said Reid, "they all see the same individual object." But according to Hamilton this statement is not "philosophically correct...the truth is that each of these persons sees a different object... It is not by perception but by a process of reasoning that we connect the objects of sense with existences beyond the sphere of immediate knowledge."² Now it is to this "beyond" that the term transsubjective is applied, and the question before us is: How do individual subjects thus get beyond the immanence or immediacy with which all experience begins? By a "process of reasoning," it is said. But it is at least true in fact, whether necessarily true or not, that such reasoning is the result of social intercourse. Further, it will be generally allowed that Kant's Analytic, before referred to, has made plain the insufficiency of merely formal reasoning to yield the categories of Substance, Cause and End, by which we pass from mere perceptual experience to that wider experience which we call knowledge, again, may claim to have shown that in fact these categories are the result of that reflective self-consciousness to which social intercourse first gives rise.

But such intercourse, it has been urged, presupposes the common ground between subject and subject which it is meant to explain. How, it is asked, if every subject is confined to his own unique experience, does this intersubjective intercourse ever arise? If so, perhaps it is not necessary to introduce an "external" factor, and all social intercourse began, such intercourse, as presupposing something more than immediate sense-knowledge, obviously never could begin.³ Let us illustrate by an analogy, which Leibnitz's assumption of experience with a "personal or material" identity suggests. If it were possible for the terrestrial astronomer to obtain observations of the heavens from astronomers in the neighbouring stars, he would be able to map in three dimensions constellations which now he can only represent in two. But unless he had an unaided the heliocentric parallax of these neighbouring stars, he would have no means of distinguishing them as far from the distant myriads besides, or of understanding the data he might receive; and unless he had an unaided the parallax of our sun, those heliocentric parallaxes would have been unattainable. So in like manner we may say "intersubjective parallax" presupposes what we may call "subjective parallax," and that this is the case with all of us, as we each refer our experiences to our own personal point of view, it may be in the interests of each to know that of others. But such subjective parallax or acquaintance with other like selves is the direct outcome of the extended range in time which memory proper secures; and when in this way self has become an object, reflectiveness, or objects become other selves or "ejects," to adopt with slight modification a term originated by the late W. K. Clifford. We may be quite sure that his faithful dog is as likely as a human being who lives among the cold-blooded fishes the battle of the stigmata to which, if we may judge by biological innence, to be found very early. Sexual union in the physiological sense occurs in all but the lowest Metazoas, pairing and courtship are frequent among insects, while "among the cold-blooded fishes the battle of the sexes" is said to lead the male to the nest which he has built, his mad dance of passion around her, and his subsequent jealous guarding of the nest, have often been observed and admired.⁴ Among birds and mammals

⁴ And it is precisely for want of this mediation that Kant's "two stems of human knowledge, which perhaps may spring from a common but to us unknown root," leave epistemology still more or less mired with the old dualism of sense and understanding.
we find not merely that these psychological aspects of sexual life are greatly extended, but we find also prolonged education of offspring by parents and imitation of the parents by offspring. Even language, or, at any rate, the linguistic impulse, is not wholly absent among these. It is thus that the environment presents the organism to its environment generally advance in complexity and range, there is a concomitant advance in the variety and intimacy of its relations, specially with individuals of its kind. It is therefore of importance, when we come to an understanding of that experience that for the individual are merely objective and phases that are also ejective as well; and once the ejective level is attained, some interchanged experience is possible. So disappears the great gulf fixed between that of the individual and interjective universal experience by rival systems in philosophy.

From this preliminary epistemological discussion we may pass on to the psychological analysis of itself. As to this, there is in the main substantial agreement; the elementary facts of mind cannot be expressed in less than three propositions—"I feel somehow," "I know something," "I do something." But here at once there arises an important question, viz., What after all are we to understand by the subject of these propositions? The proposition "I feel somehow" is not equivalent to "I know that I feel somehow." To identify the two would be to confound consciousness with self-consciousness. We are no more confined to our immediate observations here than elsewhere; but the point is that, whether seeking to analyse one's own consciousness or to infer that of a, whether discussing the association of ideas or the expression of emotions, there is always an individual self or "subject" in question. It is not enough to talk of feelings or volitions: what we mean is that some individual—man or worm—feels, strives, acts, thus or thus. Obvious as this may seem, it has been frequently either forgotten or gained. It has been forgotten among details or through the muddle of a medley of faculties, each treated as an individual in turn, and among which the real individual was lost. Or it has been gained, because to admit that all psychological facts pertain to an experiencing subject or experient to imply that they pertained to a particular spiritual substance, which was simple, indestructible, and so forth; and it was manifestly desirable to exclude such assumptions from psychology as a science aiming only at a systematic exposition of what can be known and verified by observation. But, however, much assailed or disowned, the concept of a "mind" or conscious subject is to be found implicitly or explicitly in all psychological writers whatever—not more in Berkeley, who accepts it as a fact, than in Hume, who treats it as a fiction. This being so, we are far more likely to reach the truth eventually if we openly acknowledge this inexpressible assumption, if such it prove, instead of resorting to all sorts of devious paraphrases to hide it. Now wherever the word Subject, or its derivatives, occurs in psychology we might substitute the word Ego and analogous derivatives, did such exist. Ego Subject is almost always the preferable term; its impersonal form is an advantage, and it readily recalls its modern correlative Object. Moreover, Ego has two senses, distinguished by Kant as pure and empirical, the latter of which was, of course, an object, the Me known, while the former was subject always, the I knowing. By pure Ego or Subject it is proposed to denote here the simple fact that everything experienced is referred to a Self experiencing. This psychological concept of a self or subject, then, is after all by no means identical with the metaphysical concepts of a soul or mind-atm, or of mind-stuff not atomic; it may be kept as free from metaphysical implications as the concept of the biological individual or organism with which it is so intimately connected.

The attempt, indeed, has frequently been made to resolve the former into the latter, and so to find in mind only such an individual. But such an attempt, and in the belief of the organism, i.e., what we may call an objective individuality. But such procedure owes all its plausibility to the fact that it leaves out of sight the difference between the biological and psychological standpoints. All that the biologist means by a dog is "the sum of the phenomena which make up its corporeal existence." 2 And inasmuch as its presentation to any one in particular is a point of no importance, the fact of presentation at all may be very well dropped out of account. Let us now turn to psychology: Why should we accept this "dog" and take this "dog" as a name for the series of mental phenomena which make up an individual mind? 3 Surely the moment we try distinctly to understand this question we realize that the cases are different. Series are to the mind what processes are to the organism. Now it may be that something which ex hypothesi is but a series of feelings, can be aware of itself as a series? 4 Or (2) shall we say that the several parts as the series are mutually phenomenal, much as A may look different from B, the one to the one? And thus may be the case of the organism to its environment. Or (3) shall we say that the mind may take stock of our biological dog? No, obviously only for that individual mind itself; yet that is supposed to be made up of, to be nothing different from, the series of phenomena. Are we, therefore, not "feeling," "conscious," "subjective and of the experiences of the organism to its environment? It is not a question of being aware of oneself or of oneself as a whole, but of being aware of oneself as a particular aspect of oneself, and the question of this aspect in relation to the organism to its environment.

4. From this preliminary epistemological discussion we may pass on to the psychological analysis of itself. As to this, there is in the main substantial agreement; the elementary facts of mind cannot be expressed in less than three propositions—"I feel somehow," "I know something," "I do something." But here at once there arises an important question, viz., What after all are we to understand by the subject of these propositions? The proposition "I feel somehow" is not equivalent to "I know that I feel somehow." To identify the two would be to confound consciousness with self-consciousness. We are no more confined to our immediate observations here than elsewhere; but the point is that, whether seeking to analyse one's own consciousness or to infer that of a, whether discussing the association of ideas or the expression of emotions, there is always an individual self or "subject" in question. It is not enough to talk of feelings or volitions: what we mean is that some individual—man or worm—feels, strives, acts, thus or thus. Obvious as this may seem, it has been frequently either forgotten or gained. It has been forgotten among details or through the muddle of a medley of faculties, each treated as an individual in turn, and among which the real individual was lost. Or it has been gained, because to admit that all psychological facts pertain to an experiencing subject or experient to imply that they pertained to a particular spiritual substance, which was simple, indestructible, and so forth; and it was manifestly desirable to exclude such assumptions from psychology as a science aiming only at a systematic exposition of what can be known and verified by observation. But, however, much assailed or disowned, the concept of a "mind" or conscious subject is to be found implicitly or explicitly in all psychological writers whatever—not more in Berkeley, who accepts it as a fact, than in Hume, who treats it as a fiction. This being so, we are far more likely to reach the truth eventually if we openly acknowledge this inexpressible assumption, if such it prove, instead of resorting to all sorts of devious paraphrases to hide it. Now wherever the word Subject, or its derivatives, occurs in psychology we might substitute the word Ego and analogous derivatives, did such exist. Ego Subject is almost always the preferable term; its impersonal form is an advantage, and it readily recalls its modern correlative Object. Moreover, Ego has two senses, distinguished by Kant as pure and empirical, the latter of which was, of course, an object, the Me known, while the former was subject always, the I knowing. By pure Ego or Subject it is proposed to denote here the simple fact that everything experienced is referred to a Self experiencing. This psychological concept of a self or subject, then, is after all by no means identical with the metaphysical concepts of a soul or mind-atm, or of mind-stuff not atomic; it may be kept as free from metaphysical implications as the concept of the biological individual or organism with which it is so intimately connected.

The attempt, indeed, has frequently been made to resolve the former into the latter, and so to find in mind only such an individual. But such an attempt, and in the belief of the organism, i.e., what we may call an objective individuality. But such procedure owes all its plausibility to the fact that it leaves out of sight the difference between the biological and psychological standpoints. All that the biologist means by a dog is "the sum of the phenomena which make up its corporeal existence." 2 And inasmuch as its presentation to any one in particular is a point of no importance, the fact of presentation at all may be very well dropped out of account. Let us now turn to psychology: Why should we accept this "dog" and take this "dog" as a name for the series of mental phenomena which make up an individual mind? 3 Surely the moment we try distinctly to understand this question we realize that the cases are different. Series are to the mind what processes are to the organism. Now it may be that something which ex hypothesi is but a series of feelings, can be aware of itself as a series? 4 Or (2) shall we say that the several parts as the series are mutually phenomenal, much as A may look different from B, the one to the other? And thus may be the case of the organism to its environment. Or (3) shall we say that the mind may take stock of our biological dog? No, obviously only for that individual mind itself; yet that is supposed to be made up of, to be nothing different from, the series of phenomena. Are we, therefore, not "feeling," "conscious," "subjective and of the experiences of the organism to its environment? It is not a question of being aware of oneself or of oneself as a whole, but of being aware of oneself as a particular aspect of oneself, and the question of this aspect in relation to the organism to its environment.

To admit this, of course, is to admit the necessity of distinguishing between Mind or Ego, meaning the unity or continuity of consciousness as a complex of presentations, and Mind or Ego as the subject to which all these presentations are presented. In dealing with the body from the ordinary biological standpoint no such necessity arises. But, whereas the individual organism is spoken of unequivocally, in psychology, on the other hand, the individual mind may mean either (i) the subject of the feelings for whom they are phenomena; or (ii) the subject of these feelings or phenomena plus the series of feelings or phenomena themselves, the two being in that relation to each other in which alone the one is subject and the other object. The first name suggests the last sense that Mind is used in empirical psychology. Its exclusive use in the first sense is favoured only by those who shirk from the speculative associations connected with its exclusive use in the

3. Examination of Sir W. Hamilton's Philosophy, ch. xii. fin.
4. A meaning better expressed, as said above, by experience.
Its cause, though in different circumstances the same immediate cause may produce a different amount or even a different state of feeling. Turning from what we may call the receptive phase of an experience to the active or appetitive phase, we find in like manner that feeling is certainly not—in such cases as we can clearly observe—the whole of what we experience at any moment. True, in common speech we talk of liking pleasure and disliking pain; but this is either tautology, equivalent to saying we are pleased when we are pleased and pained when we are pained; or else it is an allowable abbreviation, and means that we like pleasurable objects and dislike painful objects, as when we say we like feeling warm and dislike feeling hungry. But feeling warm or feeling hungry, we must remember, is not pure feeling in the stricter sense of the word. Within the limits of our observation, then, we find that feeling accompanies some more or less definite presentation which for the sake of it becomes the object of appetite or aversion; in other words, feeling implies a relation to a pleasurable or painful presentation or situation, that, as cause of feeling or as end of the action to which feeling prompts, is doubly distinguished from it. Thus the very facts that lead us to distinguish feeling from cognition and conception make against the hypothesis that consciousness can ever be all feeling.

But, as already said, the plausibility of this hypothesis is in good part due to a laxity in the use of terms. Most psychologists before Kant, and some even to the present day, speak of pleasure and pain as sensations. But it is plain that pleasure and pain are not simple ideas, as Locke called them, in the sense in which touches and tastes are—that is to say, they are never like these localized or processed or are they elaborated in conjunction with other sensations and movements into percepts or intuitions of the external. This confusion of feeling with sensations is largely consequent on the use of one word pain both for certain organic sensations and for the purely subjective state of being pained. But such pains not only are always more or less definitely localized—which of itself is so far cognition, they are also distinguished as shooting, burning, gnawing, &c., all which symptoms indicate a certain objective quality. Accordingly psychologists have been driven by one means or another to recognize two "aspects" (Bain), or "properties" (Wundt), in what they call a sensation, the one a "sensible or intellectual" or "qualitative," the other an "affective" or "emotive," aspect or property. The term "aspect" is figurative and obviously inaccurate; even to describe pleasure and pain as properties of sensation is open to much question. But the point with which at present concerns us is simply that when feeling is said to be the primordial element in consciousness more is usually included under feeling than pure pleasure and pain, viz., some characteristic or quality by which one pleasurable or painful sensation is distinguishable from another. No doubt, as we go downwards in the chain of life the qualitative or objective elements in the so-called sensations become less and less definite; and at the same time organisms with well-developed senses-organisms give place to others without any clearly differentiated organs at all. But there is no ground for supposing even the amoeba itself to be affected in all respects the same whether by changes of temperature or of pressure or by changes in its internal fluids, albeit all of these changes will further or hinder its life and so presumably be in some sort pleasurable or painful. On the whole, then, there are grounds for saying that the endeavour to represent all the various facts of consciousness as evolved out of feeling is due to a hasty striving after simplicity, and has been favoured by the ambiguity of the term feeling itself. If by feeling we mean a certain subjective state varying continuously in intensity and passing from time to time from its positive phase (pleasure) to its negative phase (pain), then this purely pathic state implies an agreeing or disagreeing something which psychologically determines it. If, on the other hand, we let feeling stand for both this state and the cause of it, then, perhaps, a succession of such "feelings" may make up a consciousness; but then we are including two of our elementary facts under the name of one
of them. The simplest form of psychological life, therefore, involves not only a subject but a subject having qualitatively distinguishable presentations which are the occasion of its feeling.

6. We may now try to ascertain what is meant by cognition as an essential element in this life, or, more exactly, what we are to understand by the term presentation. It was an important step onwards for psychology when Locke introduced the "new way of ideas" which Stillingfleet found alternately so amusing and so dangerous. By ideas Locke told him he meant "nothing but the immediate objects of our minds in thinking"; and it was so far a retrograde step when Hume restricted the term to certain only of these objects, or rather to these objects in a certain state, viz. as reproduced ideas or "images." And, indeed, the history of psychology seems to show that its most important advances have been made by those who have kept closely to this way of ideas; the establishment of the laws of association with their many fruitful applications and the whole Herbartian psychology may suffice as examples (see HERBART). The truth is that the use of such a term is itself a mark of an important generalization, one which helps to free us from the mythology and verbiage of the "faculty-psychologists." All the various mental facts spoken of as sensations, movements, percepts, images, intuitions, concepts, notions, have two characteristics in common: (1) they admit of being more or less attended to, and (2) they can be variously combined together and reproduced. It is here proposed to use the term presentation to denote them all, as being the best English equivalent for what Locke meant by idea and what Kant and Herbart called a Vorstellung.

A presentation has then a twofold relation—first, directly to the subject, and, secondly, to other presentations. The former relation answers to the fact that a presentation is attended to, that the subject is more or less conscious of it: it is "in his mind" or "presented" to a subject, and might with advantage be called an object, or perhaps a psychological object, to distinguish it from what are called objects apart from presentation, i.e. conceived as independent of any particular subject. Locke, as we have seen, did so call it; still, to avoid possible confusion, it may turn out best to dispense with the frequent use of object in this sense. But on one account, at least, it is desirable not to lose sight altogether of this, which is after all the stricter as well as the older signification of object, namely, because it enables us to express definitely, without implicating any ontological theory, what we have so far seen reason to think is the fundamental fact in experience. Instead of depending mainly on that vague and treacherous word "consciousness," or committing ourselves to the position that ideas are modifications of a certain mental substance or identical with the subject to whom they are presented, we may leave all this on one side, and say that ideas are objects, and the relation of objects to subjects—that whereby the one is object and the other subject—is presentation; and it is because only objects sustain this relation that they may be spoken of simply as presentations. On the side of the subject this relation implies what, for want of a better word, may be called attention, extending the denomination of this term so as to include even what we ordinarily call inattention. Attention so used will thus cover part of what is meant by consciousness—so much of it, that is, as answers to being mentally active, active enough at least to "receive impressions." Attention on the side of the subject implies intensity on the side of the object: we might indeed almost call intensity the matter of a presentation, without which it is a nonentity.

The inter-objective relations of presentations, on which Continuity of Consciousness depends, though of the first importance, are in themselves hardly call for consideration in a general analysis like the present. But there is one point still more fundamental that we cannot wholly pass by; it is—in part at any rate—what is commonly termed the unity or continuity of consciousness. From the physical standpoint and in ordinary life we can talk of objects that are isolated and independent and in all respects distinct individuals. The screech of the owl, for example, has physically nothing to do with the brightness of the moon: either may come or go without changing the order of things to which the other belongs. But psychologically, for the individual perceiver, they are parts of one whole; the more his attention is given to the one the more it is taken from the other. Also the actual recurrence of the one will afterwards entail the re-presentation of the other also. Not only are they still parts of one whole, but such distinctness as they have at present is the result of a gradual differentiation.

It is quite impossible for us now to discuss the effects of years of experience removed, or to picture the character of our infantile presentations before the fox to prol is, and habitually to concentrate attention on some and to ignore others. In place of the many things which we can now see and hear, not merely would there then be a confused presentation of the whole field of vision and of a mass of undistinguished sounds, but even the difference between sights and sounds themselves would be without its present distinctness. Thus the further we go back the nearer we approach to a total presentation having the character of one general continuum in which differences are latent. There is, then, in psychology, as in biology, what may be called a principle of "progressive differentiation or specialization," and this, as well as the facts of reproduction and association, forcibly suggests the conception of a certain objective continuum forming the background or basis to the several relatively distinct presentations that are elaborated out of it—the equivalent, in fact, of that unity and continuity of consciousness which has been supposed to supersede the need for a conscious subject.

There is one class of objects of special interest even in a general survey, viz. movements or motor presentations. These, like sensory presentations, admit of association and reproduction, and seem to attain to such distinctness as they possess in adult human experience by a gradual differentiation out of an original diffused mobility which is little besides emotional expression. Of this, however, more presently. It is primarily to such dependence upon feeling that movements owe their distinctive character, the possession, that is, under normal circumstances, of definite and assignable psychical antecedents, in contrast to sensory presentations, which are devoid of them. We cannot psychologically explain the order in which particular sights and sounds occur; but the movements that follow them, on the other hand, can be adequately explained only by psychology. The twilight that sends the bees to work in the early morning, the lion's roar which gathers the jackals to the sheep. Such diversity in the movements, although the sensory presentations are similar, is due, in fact, to what we might call the principle of "subjective or hedonic selection"—that, out of all the manifold changes of sensory presentation which a given individual experiences, only a few are the occasion of such decided feeling as to become objects of possible appetite or aversion. It is thus by means of movements that we are more than the creatures of circumstances and that we can with propriety talk of subjective selection. The representation of what interests us comes then to be associated with the representation of such movements as will secure its realization, so that—although no concentration of attention will secure the requisite intensity to a pleasurable object present only in idea—we can by what is strangely like a concentration of attention convert the idea of a movement into the fact, and by means of the movement attain the coveted reality.

1 Cf. Kant's Principle of the Anticipations of Perception: "In all phenomena the real, which is the object of sensation, has intensive magnitude.

2 The biological principle referred to is that known as von Baer's law, viz. that the progress of development is from the general to the particular."
7. And this has brought us round naturally to the third of the commonly accepted constituents of experience. What is *conation*, or rather *conative action*? For there are two questions more often or less confused, the question of motive or spring of action, as it is sometimes called—why is there action at all? and the question of means—how do definite actions come about? The former question relates primarily to the connexion of conation and feeling. It is only the latter question that we now raise. In ordinary voluntary movement we have first of all an idea or re-presentation of the movement, and last of all the actual movement itself—a new presentation which may for the present be described as the filling out of the re-presentation, which thereby attains that intensity, distinctness and embodiment we call reality. How does this change come about? The attempt has often been made to explain it by a reference to the more uniform, and apparently simpler, case of reflex action, including under this term what are called sensori-motor and ideo-motor actions. In all these the movement seems to be the result of a mere transference of intensity from the associated sensation or idea that sets on the movement. But when by some chance or mischance the same sensory presentation excites two or more nascent motor changes that conflict, a temporary block is said to occur; and, when at length one of these nascent motor changes finally prevails, then, it is said, "there is constituted a state of consciousness which displays what we term volition." But this assumption that sensory and motor ideas are associated before volition, and that volition begins when automatic or reflex action ends, is due to that ineretive habit of confounding the psychical and the physical which is the bane of modern psychology. How did these particular sensory and motor presentations ever come to be associated? The only psychological evidence we have of any very intimate connexion between sensory and motor representations is that furnished by our acquired dexterities, *i.e.* by such movement as Hartley styled "secondarily automatic." But then all these have been preceded by volition; as Herbert Spencer says, "the child learning to walk wills each movement before making it." Summarizing then, a psychologist should take this as his typical case and prefer to assume that all automatic actions that come within his ken at all are in this sense secondarily automatic, *i.e.* to say that either in the experience of the individual or of his ancestors, volition or something analogous to it, preceded habit.

But, if we are thus compelled by a sound method to regard sensori-motor actions as degraded or mechanical forms of voluntary actions, instead of regarding voluntary actions as gradually differentiated out of something physical, we have not to ask: What happens when one of two alternative movements is executed? but the more general question: What happens when any movement is made in consequence of feeling? It is obvious that on this view the simplest definitely *purposive* movement must have been preceded by some movement simpler still. For any distinct movement purposely made presupposes the ideal presentation, before the actual realization, of the movement. But such ideal presentation, being a re-presentation, necessarily presupposes a previous actual movement of which it is the so-called mental residuum. There is then, it would seem, but one way left, viz. to regard those movements which are immediately expressive of pleasure or pain as primordial, and to regard the so-called voluntary movements as elaborated out of these. The vague and diffusive character of these primitive emotional manifestations is really a point in favour of this position. For such "diffusion" is evidence of an underlying continuity of motor presentations parallel to that already discussed in connexion with sensory presentations, a continuity which, in each case, becomes differentiated in the course of experience into comparatively distinct and discrete movements and sensations respectively.¹

---

¹ Compare Spencer's *Principles of Psychology*, i, §§ 217, 8.
³ It may be well to call to mind here that Alexander Bain also regarded emotional expression as a possible commencement of action, but whereas we can only infer, and that in a very roundabout fashion, that our sensations are not absolutely distinct but are parts of one massive sensation, as it were, we are still liable under the influence of strong emotion to experience the corresponding continuity in the case of movement. Such motor-continuum we may suppose is the psychical counterpart of that permanent readiness to act, or rather that continual nascent acting, which among the older physiologists was spoken of as "tonic action." This "skeletal tone," as it is now called, is found to disappear more or less completely from a limb when its sensory nerves are divided. "In the absence of the usual stream of afferent impulses passing into it, the spinal cord ceases to send forth the influences which maintain the tone." And a like intimate dependence, we have every reason to believe, obtains throughout between sensation and movement. We cannot imagine the beginning of life but only life begun. The simplest picture, then, which we can form of a concrete state of mind is not one in which there are movements before there are any sensations or sensations before there are any movements, but one in which change of sensation is followed by change of movement, the link between the two being a change of feeling.

Having thus simplified the question, we may now ask again: How is this change of movement through feeling brought about? The answer, as already hinted, appears to be: *Dependence of Action on Feeling.* We learn from such observations as psychologists describe under the head of fascination, imitation, hypnotism, &c., that the mere concentration of attention upon a movement is often enough to bring the movement to pass. But, of course, in such cases neither emotion nor volition is necessarily implied; but none the less they show the close connexion that exists between attention and movement. Everybody, too, must often have observed how the execution of any but mechanical movements arrests attention to thoughts or sensations, and how, vice versa, a striking impression or thought interrupts him in the performance of skilled movements. Let us suppose, then, that we have at any given moment a certain distribution of attention between sensory and motor presentations; a change in that distribution then will mean a change in the intensity of some of all of these. But, in the case of motor presentations, change of intensity means change of movement. Such changes are, however, quite minimal in amount so long as the given presentations are not conspicuously agreeable or disagreeable. So soon as they are, however, there is evidence of a most intimate connexion between feeling and attention; but it is hardly possible adequately to exhibit this evidence without first attempting to ascertain the characteristics of the presentations, or groups of presentations, that are respectively pleasurable and painful, and this must occupy us later on.

8. We are now at the end of our analysis, and the results may perhaps be most conveniently summarized by first throwing them into a tabular form and then appending a few remarks by way of induction. The following is a tabular arrangement of the table. Taking the first case of the specific difference between one concrete state of mind and another, and supposing that we are dealing with presentations but only to reject it in favour of his own peculiar doctrine of "sponginess," which, however, is open to the objection that it makes movement precede feeling instead of following it—an objection which Bain would be unable to sustain—yet his hypothesis was as cogent as only Bain supposed them to be. Against the position maintained above he objects that "the emotional wave almost invariably affects a whole group of movements," and he even goes so far as to say that "isolated promptings that are desiderated in the case of the will" (Mental and Moral Science, p. 332). But to make this objection is to let heredity count for nothing. In fact, wherever a variety of isolated movements is physically possible there also we always find corresponding instincts, "that untaught ability to perform actions," to use Bain's own language, which a minimum of practice suffices to perfect. But then these suggest gradual ancestral acquisition.

¹ Foster, *Text-Book of Physiology*, § 597.
in their simplest form, i.e. as sensations and movements, we have:

\[
\begin{align*}
(1) & \text{ non-voluntarily attending to changes in the sensory-continuum; } & \text{Presentation of sensory} \\
& \text{[Cognition]} & \text{OBJECTS.}
\end{align*}
\]

\[
\begin{align*}
(2) & \text{ being, in consequence, either pleased or} & \text{Presentation of motor} \\
& \text{[Feeling]} & \text{PRODUCTING CHANGES IN THE MOTOR-CONTINUUM.}
\end{align*}
\]

Of the three phases or functions, thus analytically distinguishable, but not really separable, the first and the third correspond in the main with the receptive and active states or powers of the older psychologists. The second, being more difficult to isolate, is long overlooked; or, at all events, its essential characteristics were not distinctly marked, so that it was confounded either with (1) which is its cause, or with (3), its effect. But perhaps the most important of all psychological distinctions is that which traverses both the old bipartite and the prevailing tripartite analysis, viz. that between the subject on the one hand, as acting and feeling, and the objects of this activity on the other. With this distinction clearly before us, instead of crediting the subject with an indefinite number of faculties or capacities, we must seek to explain not only reproduction, association, &c., but all varieties of thinking and acting, by the laws pertaining to ideas or presentations, leaving to the subject only the one power of variously distributing that attention upon which the intensity of a presentation in part depends. What we call activity in the narrower sense (as e.g. purposive movement and intelligence) is but a special form of this single subjective activity, although a very important one.

According to this view, then, presentations, attention, feeling, are not to be regarded as three co-ordinate genera, each of which is a complete "state of mind or consciousness," i.e. as being all alike included under this one supreme category. There is, as Berkeley long ago urged, no resemblance between activity and an idea; nor is it easy to see anything common to pure feeling and an idea, unless it be that both possess intensity. Classification seems, in fact, to be here out of place. Instead, therefore, of the one sumnum genus, state of mind or consciousness, with its three co-ordinate subdivisions—cognition, emotion, co-ordination—our analysis seems to lead us to recognize three distinct and irreducible components—attention, feeling, and objects or presentations—as together, in a certain connexion, constituting one concrete state of mind or psychosis. Of such concrete states of mind or psychoses we may then say—so far agreeing with the older, bipartite psychology—that they are two forms, corresponding to the two ways in which attention may be determined and the two classes of objects attended to in each, viz. (1) the sensory or receptive attitude, when attention is non-voluntarily determined, i.e. where feeling follows the act of attention; and (2) the motor or active attitude, where feeling precedes the act of attention, which is thus determined voluntarily.

**Attention.**

9. Instead of a congeries of faculties we have assumed a single subjective activity and have proposed to call this attention. Some further explanation of this position seems to be desirable. We start with the duality of subject and object as fundamental. We say of man, mouse, or monkey that it feels, perceives, remembers, infers, strives, and so forth. Leaving aside the first term, it is obvious that all the rest imply both an activity and an object. Is it possible to resolve these instances into a form in which the assumed diversity of the act will appear as a diversity of the object? At first sight it looks rather as if the kind of activity might vary while the object remained the same; that e.g. we perceived an object and later on remembered or desired it. It would then be most natural to refer these several activities to corresponding faculties of perception, memory and desire. This, indeed, is the view embodied in common speech, and for practical purposes it is doubtless the simplest and the best. Nevertheless, a more thorough analysis shows that when the supposed factor is different the object is never entirely and in all respects the same. Thus in perception, e.g. we deal with "impressions" or primary presentations, and in memory and imagination with "ideas" (in the later sense) or secondary presentations. In desire the want of the object gives it an entirely different setting, adding a new characteristic, that of value or worth, so that its acquisition becomes the end of a series of efforts or movements. The older psychology, by its acceptance of the Cartesian doctrine that all the facts of immediate experience are to be interpreted as subjective modifications, failed to distinguish adequately between the subject as active and the objects of its activity. Hence the tendency to rest content with the popular distinction of various faculties in spite of the underlying sameness implied in the common application of "conscious" to them all. In fact, Locke's definition of idea (in the older and wider sense) as the immediate object of consciousness or thinking was censured by Reid as "the greatest blinshem in the Essay on Human Understanding." But, accepting this definition as implied in the duality of subject and object, and accepting too the underlying sameness which the active form "conscious" undeniably implies, we have simply to ask: "Which is the better term to denote this common element—consciousness or attention?"

Consciousness, as the vaguest, most protean and most treacherous of psychological terms, will hardly serve our purpose. Attention, on the other hand, has an invariable active sense, and there is an appropriate verb, to attend. But many things, it may be said, are presented while few are attended to; if attention is to be made coextensive with the activity implied in consciousness, will not the vital distinction between attention and inattention be lost? In fact, however, this distinction implies a covert comparison, not an absolute contrast. In everyday life we recognize many degrees of attention, ranging from an extreme of intense concentration to one of complete remission, as Locke long ago pointed out. Between these extremes there is perfect continuity, and not a difference of kind; to apply the one term attention to the whole range is very like applying the one term magnitude to large and small quantities alike.

But it is not enough to show that when we commonly talk of different faculties we also find psychological differences of object, and to assert that if there is one common factor in all psychological activity this factor is attention. To make our position secure it is needful to show directly that all the various faculties with which a subject can be credited are resolvable into attention and various classes or relations or states of presentations that are attended to. How far this is possible remains to be seen as we proceed. In the meantime, it is only a "phantom power" the position is generally conceded, but so far as the attentionary or active powers are concerned it is as generally denied. Now, in so far as volition implies not merely action, overt or intended, but also motives, in so far also it must be acknowledged it contains a factor not resolvable into attention to motor presentations. This further factor, which has been called "the volitional character of feeling," we here leave aside. Apart from this direct spring of action, then, the question is whether the active process itself differs from the cognitive or receptive process

\[\ldots\]

1. To cover more complex cases we might here add the words "or trains of ideas."
save in being attention to a special class of objects. First of all, it is noteworthy that both have the same characteristics. This, what Hamilton called "the law of limitation," holds of each alike and of either with respect to the other; and it holds too not only of the number of presentations but also of the intensity. We can be absorbed in action just as much as in perception or thought; also, as already said, movements, unless they are mechanical, inhibit ideas; and vice versa, ideas, other than associated trains, arrest movements. Intoxication, hypnosis or insanity, rest or exhaustion, tell on apperception as well as on innervation. The control of thoughts, equally with the control of movements, requires effort; and as there is a strain peculiar to intently listening or gazing, which is known to have a muscular concomitant, so too there is a strain characteristic of recollection and visualization, which may quite well turn out to be muscular too. When movements have to be associated, the same continuous attention is called for as is found requisite in associating sensory impressions; and, when such associations have become very intimate, dissociation is about equally difficult in both cases.

There is one striking fact that brings to light the essential sameness of apperception and innervation, cited by Wundt for this very purpose. In so-called "reaction-time" experiments it is found, when the impression to be registered follows on a premonitory signal after a certain brief interval, that then the reaction (registering the impression) is often instantaneous; the reaction-time, in other words, is nil. In such a case the subject is aware not of three separate events, (1) the perception of the impression; (2) the reaction; (3) the perception of this; but the fact of the impression is realized and the registering movement is actualized at once and together the subject is conscious of one act of attention and one only.

Theory of Presentations.

10. We come now to the exposition of the objects of attention or consciousness, i.e. to what we may call the objective or presentational factor of psychic life. The treatment of this will fall naturally into two divisions. In the first we shall have to deal with its general characteristics and with the fundamental processes which all presentation involves. In view of its general and more or less hypothetical character we may call it the theory of presentation. We can then pass on to the special forms of presentations, known as sensations, percepts, images, &c., and to the special processes to which these forms lead up.

This exposition will be simplified if we start with a supposition that will enable us to leave aside, at least for the present, the difficult question of heredity. We know that in the course of each individual's life there is more or less of progressive differentiation or development.

Further, it is believed that there has existed a series of sentient individuals beginning with the lowest form of life and advancing continuously up to man. Some traces of the advance already made may be reproduced in the growth of each human being born, but for the most part such traces have been obliterated. What was experience in the past has become instinct in the present. The descendant has no consciousness of his ancestor's failures when performing by "an untaught ability" what his progenitor perhaps painfully acquired. But, if we are to attempt to follow the genesis of mind from its earliest dawn, it is the primary experience rather than the eventual instinct that we have first of all to keep in view. To this end, then, it is proposed to assume that we are dealing with one individual who has continuously advanced from the beginning of psychic life, and not with a series of individuals of whom all save the first inherited certain capacities from their progenitors. The life-history of such an imaginary individual, that is to say, would correspond with all that was new in the experience of a certain typical series of individuals each of whom advanced a certain stage in mental differentiation. On the other hand, from this history would be omitted that inherited reproduction of the net results, so to say, of ancestral experience, that innate tradition by which alone, under the actual conditions of existence, progress is possible. The process of thus reproducing the old might differ widely from that of producing the new as electrophotographing does from engraving. However, the point is that as psychologists we know nothing directly about it; neither can we distinguish precisely at any link in the chain of life what is old and inherited—original in the sense of Locke and Leibnitz—from what is new or acquired—original in the modern sense. But we are bound as a matter of method to suppose all complexity and differentiation among presentations to have been originated, i.e. experimentally acquired, at some time or other. So long, then, as we are concerned primarily with the progress of this differentiation we may disregard the fact that it has not actually been, as it were, the product of one hand dealing with one tabula rasa to use Locke's—originally Aristotle's—figure, but of many hands, each of which, starting with a reproduction of what had been wrought on the preceding tabulae, put in more or fewer new touches before devising the whole to a successor who would proceed in like manner.

11. What is implied in this process of differentiation and development is, if that becomes differentiated—these are the questions to which we must turn. Each individual is, of course, usually represented mental advance as consisting fundamentally in the combination and recombination of various elementary units, the so-called sensations and primitive movements: in other words, as consisting in a species of "mental chemistry." If we are to resort to physical analogies at all—a matter of very doubtful propriety—we shall find in the growth of a seed or an embryo far better illustrations of the unfolding of the contents of consciousness than in the building up of molecules: the process seems much more a segmentation of what is originally continuous than an aggregation of elements at first independent and distinct. Comparing higher minds or stages of mental development with lower—by what means such comparison is possible we need not now consider—we find in the higher conspicuous differences between presentations which in the lower are indistinguishable or absent altogether. The worm is aware only of the difference between light and dark. The steel-worker sees half a dozen tints where others see only a uniform glow. To the child it is said, it is green or blue; and throughout life we are apt to note the general, the points of resemblance, before the special, the points of difference. But even when most definite, what we call a presentation is still part of a larger whole. It is not separated from other presentations, whether simultaneous or successive, by something which is not of the nature of presentation, as one island is separated from another by the intervening sea, or one note in a melody from the next by an interval of silence. In our search for a theory of presentations, then, it is from this "continuity of consciousness" that we must take our start. Working backwards from this as we find it now, we are led alike by particular facts and general considerations to the conception of a totum objectivum or objective continuum which is gradually differentiated, thereby giving rise to what we call distinct presentations, just as some particular presentation, clear as a whole, as Leibnitz would say, becomes with mental growth a complex of distinguishable parts. Of the very beginning of this continuum we shall say nothing; the beginnings are, indeed, the pale of science. Experience advances as this continuum is differentiated, every differentiation being a change of presentation. Hence the commonplace of psychologists—We are only conscious as we are conscious of change.

But "change of consciousness" is too loose an expression to take the place of the unwieldy phrase differentiation of a presentation-continuum, to which we have been driven. For not only does the term "consciousness" confuse what exactness requires us to keep distinct, an activity and its object, but also the term "change" fails to express the characteristics which distinguish new presentations from other changes. Differentiation implies that the simple becomes complex or the complex more complex; it implies also that this increased complexity is due to the persistence of former changes; we may even say such persistence is
not the whole of it, for in this experience of massive sensation alone it is impossible to find other elements which an analysis of spatial intuition unmistakably yields. Extensity and extension, then, are not to be confounded. Now, we find, even at our level of mental evolution, that an increase in the intensity of a sensation is apt to entail an increase in its extensity too. In like manner we observe a greater extent of movement in emotional expression when the intensity of the emotion increases. Even the higher region of imagination is no exception, as is shown by the whirl and confusion of ideas incident to delirium, and, indeed, to all strong excitement. But this "diffusion" or "radiation," as it has been called, diminishes as we pass from the class of organic sensations to the sensations of the five senses, from movements expressive of feeling to movements definitely purposive, and from the tumult of ideas excited by passion to the steadier sequences determined by efforts to think. Increased differentiation seems, then, to be intimately connected with increased "restriction." Probably, also, we shall find certain initial differentiations which for psychology are ultimate facts that it cannot explain. As already said, the very beginning of experience is beyond us, though it is our business—working from within—to push back our analysis as far as we can. But some differentiations being given, then it may be safely said that, in accordance with what we have called the principle of subjective selection (see § 6), attention would be voluntarily concentrated upon certain of these and upon the voluntary movements specially connected with them. To such subjectively initiated modifications of the presentation-continuum, moreover, we may reasonably suppose "restriction" to be in large measure due. But increased restriction would render further differentiation of the given whole of presentation possible, and so the two processes might supplement each other. These processes have now proceeded so far that at the level of human consciousness we find it hard to form any tolerably clear conception of a field of consciousness in which an intense sensation, no matter what, might—so to say—diffuse over the whole. Colours, e.g. are with us so distinct from sounds that—except as regards the excitement of attention or the drain upon it—there is nothing in the intensest colour to affect the simultaneous presentation of a sound. But at the beginning whatever we regard as the earliest differentiation of sound might have been incorporeal with the earliest differentiation of colour, if sufficiently diffused, much as a field of sight all blue is now incorporeal with one all red. Or, if the stimuli appropriate to both were active together, the resulting sensation might have been not a blending of two qualities, as purple is said to be a blending of red and violet, but rather a neutral sensation without the specific qualities of either. Now, on the other hand, colours and sounds are necessarily so far localized that we are directly aware that the eye is concerned with the one and the ear with the other. This brings us to our notice a fact so ridiculously obvious that it has never been deemed worthy of mention, although it has undeniably important bearings—

the fact, viz. that certain sensations or movements are an absolute bar to the simultaneous presentation of other sensations or movements. We cannot see an orange as at once yellow and green, though we can feel it at once as both smooth and cool; we cannot open and close the same hand at the same moment, but we can open one hand while closing the other. Such incorporeal or contrariety is thus more than mere difference, and occurs only between presentations belonging to the same sense or to the same group of movements. Strictly speaking, it does not always occur even then; for red and yellow, hot and cold, are presentable together provided they have certain other differences which we shall meet again presently as differences of "local sign." In the preceding paragraphs we have had occasion to distinguish between the presentation-continuum or whole field of consciousness, as we may for the present call it, and those several differentiations within this field, which are ordinarily spoken of as presentations, and to which—now that their true character as parts is clear—
THEORY OF PRESENTATIONS]

we too may confuse the term. But it will be well in the next place, before inquiring more closely into their characteristics, to consider for a moment that persistence of preceding modifications which the principle of progressive differentiation implies. This persistence is best spoken of as retentiveness. It is often confused with memory, though this is something much more complex and special; for in memory there is necessarily some contrast of past and present, whereas here there is simply the persistence of the old. But what is it that persists? On our theory we must answer, the continuum as differentiated, not the particular differentiation as an isolated unit. If psychologists have erred in regarding the presentations of one moment as merely a plurality of units, they have erred in like manner concerning the so-called residua of such presentations. As we see a certain colour or a certain object again and again, we do not go on accumulating images or representations of it, which are somewhat crowded together like shades on the banks of the Styx; nor is such colour, or whatever it be, the same at the hundredth time of presentation as at the first, as the hundredth impression of a seal on wax would be. There is no such lifeless fixity in mind. The explanations of perception most in vogue are far too mechanical and, so to say, atomistic; but we must fall back upon the unity and continuity of our presentation-continuum if we are to get a better. Suppose that in the course of a few minutes we take half a dozen glances at a strange and curious flower. We have not as many complex presentations which we might symbolize as \( F_1, F_2, \ldots, F_4 \). But rather, at first only the general outline is noted, next the disposition of petals, stamens, &c., then the attachment of the anthers, position of the ovary, and so on; that is to say, symbolizing the whole flower as \( \{p'(a'b') s'(c'd') o'(f')g'\} \), we first apprehend say \( p' \) \( \ldots \) \( o' \), then \( p' (a'b') s'(c'd') \), or \( p'(a')s'(c')o'(f') \), and so forth. It is because the traits first attended to persist that the latter form an addition to them till the complex is at length complete. There is nothing in this instance properly answering to what are known as the reproduction and association of ideas; in the last and complete apprehension as much as in the first vague and inattentive outline: we therefore have there as a primary presentation. There is a limit, of course, to such a procedure, but the instance taken, we may safely say, is not such as to exceed the bounds of a simultaneous field of consciousness. Assuming that such increase of differentiation through the persistence of preceding differentiations holds of the presentation-continuum as a whole, we conclude that, in those circumstances in which we now have a specific sensation of, say, red or sweet, there would be for some more primitive experience nothing but a vague, almost organic, sensation, which, however, would persist, so that on a repetition of the circumstances it could be again further differentiated. The earlier differentiations, in short, do not disappear like the waves of yesterday in the calm of today, nor yet last on like old scars beside new ones; but rather the two are blended and combined, so that the whole field of consciousness, like a continually growing picture, increases indefinitely in complexity of path.

**Relativity.**—The proposition in which later differentiations blend with and thereby further restrict and specialize what is retained of earlier and less definite presentations, is thus a further implication of the principle of the progressive development of the presentational continuum. When not ignored altogether this further process has been called re-association and is more simply in the form of "association set afresh," its peculiarity being, as it was supposed, that the presentations associated—though numerically distinct—were in quality perfectly identical. In point of fact, both these assumptions seem to be erroneous. The idea of a sudden "restoration instantaneous of all faculties," as a result of the experience there subject there is apparently at this stage—as we have already urged—neither the numerical distinctness nor the qualitative identity which the words "past impression (A) and present impression (B)" and "association set afresh" allude to. Still the connexion between this process of mere blending or fusion, which we shall call assimilation, and the process of association proper is so close, and the detailed analysis called for, so complex, that we must needs defer further discussion till we come to the general treat of association as a whole (cf. below, § 24). It may then be possible to show that we have here to do with a process

---

1 As, e.g. in interpreting the conduct of children as if they were already "grown-up" persons; cf. J. Ward, 2d. of Spec. Phil. (1882), pp. 369 fin. 374; James, Prin. of Psych. (1890), i. 196.

2 The Works of Thos. Reid, supplementary note, p. 932.
as being akin to feeling and so distinct from special presentations, should in any way confound the two. The mistake is perhaps accounted for by the fact that Bain, in common with the rest of his school, nowhere distinguishes between attention and the presentations that are attended to. If "change of impression" and being conscious or mentally alive are the same thing, it is then manifestly tautological to say that one is the indispensable condition of the other. If they are not the same thing, then the succession of shocks or surprises cannot wholly determine the impressions which successively determine them.

But we have still to consider whether the impressions themselves are nothing but differences or contrasts. "We do not know any one thing of itself but only the difference between it and another thing," said Bain. But it is plain we cannot speak of contrast or difference between two states or things as a contrast. If, therefore, the states or things are not themselves presented; the so-called contrast or difference then is not really a single presentation, and its supposed "relativity" but an inference. Difference is not more necessary to the presentation of two objects than two objects to the presentation of difference. And, what is more, a difference between presentation is not at all the same thing as the presentation of that difference. The former must precede the latter; the latter, which requires active comparison, need not follow. There is an ambiguity in the words "know," "knowledge," which Bain seems not to have considered: "to know" may mean either to perceive or apprehend, or it may mean to understand or comprehend. Knowledge in the first sense is only what we shall have presently to discuss as the recognition or assimilation of an impression (see below, § 18); knowledge in the latter sense is the result of intellectual comparison and is embodied in a proposition. Thus a blind man who cannot know light in the first sense can know about light in the second if he studies an treatise on optics. Now in simple perception or recognition we cannot with any exactness say that two things are perceived: straight is a thing, i.e. a definite object presented; not so not-straight, which answers to no definite object at all. Only when we rise to intellectual knowledge is it true to say: "No one could understand the meaning of a straight line without being shown a line not straight, a bent or crooked line." Two distinct presentations are necessary to the comparison that is here implied; but we must first recognize our objects before we can compare them, and this further step we may never take. We need, then, to distinguish between the comparativity of intellectual knowledge, which we must admit—for it rests at bottom on a purely analytical proposition—and the differential theory of presentations, which, however, plausible at first sight, must be wrong. We already asserted it limits us to absurdities. Thus, if we cannot have a presentation X but only the presentation of the difference between Y and Z, it would seem that in like manner we cannot have the presentation of Y or Z, nor therefore of their difference X, till we have had the presentation of A and B say, which differ by Y, and of C and D, which we may suppose differ by Z.

The lurking error in this doctrine, that all presentations are but differences, may perhaps emerge if we examine more closely what may be meant by difference. We may speak of (a) differences in intensity between sensations supposed to be qualitatively identical, as e.g. between the taste of strong and weak tea; or of (b) differences in quality between presentations of the same sense, as e.g. between red and green; or of (c) differences between presentations of different senses, as e.g. between blue and bitter. Now as regards (a) and (b) it will be found that the difference between two intensities of the same quality, or between two qualities of the same order, may be itself a distinct pre-

1 Other languages give more prominence to this distinction; compare vivere and aebbe, nossere and scire, kennen and wissen, content and andere. On this subject there is a passage in a little-known book, the Exploratio philosophica, of Professor J. Grote. Hobbes, too, was well awake to this difference, as e.g. when he says, "There are two kinds of knowledge; the one, sense or knowledge original and remembrance of the same: the other, knowledge of the truth of propositions, derived from understanding." Bain, Logik, i. 3.

2 This is a very distinct point. We have said that sensations, that is to say, in passing from a load of 10 lb to one of 20 lb, for example, or from the sound of a note to that of its octave, it is possible to experience the change continuously, and to estimate it as one might the distance between two places on the same road. But nothing of this kind holds of (c). In passing from the scent of a rose to the sound of a gong or a string from a bee we have no such means of bringing the two into relation—scarcely more than we might have of measuring the length of a journey made partly on the common earth and partly through the looking-glass. In (c), then, we have only a diversity of presentations, but not a special presentation of difference; and we only have more than this in (a) or (b) provided the selected presentations occur together. We say that we know the difference between a sound and a taste; but what we mean is simply that we know what it is to pass from attending to the one to attending to the other. It is simply a change of attention. Change, however, implies continuity, and there is continuity here in the movement of attention and the affective state consequent on that, but not directly in the qualities themselves.

3 If red follows green we may be aware of a greater difference than we could if red followed orange; and we should ordinarily call a 10 lb load heavy after one of 5 lb and light after one of 20 lb. Facts like these is it which make the differential theory of presentations plausible. On the strength of such facts Wundt has formulated a law of relativity, free, apparently, from the objections just urged against Bain's doctrine. It runs thus: "Our sensations afford no absolute but only a relative measure of external impressions. The intensities of stimuli, the pitch of tones, the qualities of light, we apprehend (empfinden) in general only according to their mutual relation, not according to any unalterably fixed unit given along with or before the impression itself." But if true this law would make it quite immaterial what the impressions themselves were: provided the relation continued the same, the sensation would be the same too, just as the ratio of 2 to 1 is the same whether our unit be miles or millimetres. In the case of intensities, e.g. there is a minimum sensible and a maximum sensible. The existence of such extremes is alone sufficient to turn the flank of the thoroughgoing relativists; but there are instances enough of intermediate intensities that are directly recognized. A letter-sorter, for example, who identifies an ounce or two ounces with remarkable exactness identifies each for itself and not the first as half the second; of an ounce and a half or of three ounces he may have a comparatively vague idea. And so generally within certain limits we can identify intensities, each for itself, neither referring to a common standard nor to one that varies from time to time—to any intensity, that is to say, that chances to be simultaneously presented; just as an enlisting sergeant will recognize a man fit for the Guards without a yard measure and whether the man's comrades are tall or short. As regards the qualities of sensations the outlook of the relativists is, if anything, worse. In what is called Meyer's experiment (described under Visum) what appears greenish on a red ground will appear of an orange tint on a ground of blue; but this contrast is only possible within certain very narrow limits. In fact, the phenomena of colour-contrast, so far from proving, distinctly disprove that we apprehend the qualities of light only according to their mutual relation. In the case of tones it is very questionable whether such contrasts exist at all. Summing up on the particular doctrine of relativity of which Wundt is the most distinguished adherent, the truth seems to be that in some cases where two presentations whose difference is itself presented occur in close connexion, this difference—as we indirectly learn—exerts a certain bias on the assimilation or identification
of one or both of the presentations. There is no "unalterably
fixed unit," certainly, but, on the other hand, "the mutual
relations of impressions" are not everything.

15. The term "field of consciousness" has occurred sundry
times in the course of this exposition: it is one of several em-
ployed in describing what have been incidentally
subconsciousness.
referred to as "degrees or grades of consciousness" —a
difficult and perplexing topic that we must now endeavour
further elucidate. Sailors steering by night are said to look
at the pole-star, "the cynosure of every eye," but this does not
prevent them from seeing the rest of the starry vault. At a
conversazione we may listen to some one speaker while still
hearing the murmur of other voices, and while listening we may
also see the speaker and thereby identify him the better. What
in these instances is looked at or listened to has been called the
"focus" of consciousness, the rest of what is heard or seen or
otherwise presented being called the "field" within which
attention is thus concentrated or brought to a point. Of these
objects beyond the focus we have then only a lower degree of
consciousness, and the more "distant" they are from the
centre of interest the fainter and obscurer they are supposed
to be or to become. Now, it is obvious that the continuity here
implied, if strictly taken, logically commits us to a field of con-
sciousness extending with ever diminishing intensity \textit{ad in-
definitum}.
But we have next to notice certain new features that
have led psychologists to give to the term field of con-
sciousness a more restricted meaning. A meteor flashing
across the sky would certainly divert the helmsman's attention,
and for the nonce he would look at that and not at the star in
the Little Bear's tail; a voice at our elbow accosting us, we
should turn to the new speaker and listen to him, still hearing
it may be, but no longer "following," the discourse thus for
us interrupted. In these cases a change in the field of con-
sciousness brings about a non-voluntary change in the focus.
But it only does so provided it is sufficiently intense and abrupt,
and the more attention is already concentrated the less effective
a given disturbance will be. A whole swarm of meteors might
have streaked the sky unheeded while Ulysses, life in hand,
steered between Scylla and Charybdis, just as all the din of the
siege failed to distract Archimedes bent over his figures in the
sand. On the other hand, we can voluntarily transfer the focus
of consciousness to any object within the field, provided again
this is sufficiently differentiated from the rest. But, more than
that, we can not only of our own motion turn to look at or
to listen to what we have only seen or heard, but not noticed before;
we can also look out or listen for something not as yet distinguish-
able, perhaps not as yet existing at all. And here again the con-
centration of attention may be maximal, as when a shipwrecked
crew scan the horizon for a sail, or a beleaguered troop hearken
for the oncoming of rescue. Now, such anticipated presentations
as soon as they are clearly discernible have already a certain
finite intensity, and so they are said to have passed over "the
threshold." See Hume's new classic phrase—and to have entered the field of consciousness. Afterwards any further
increase in their intensity is certainly gradual; are we then to
suppose that before this their intensity changed instantly from
zero to a finite quantity and not rather that there was an ultra-
liminal or subliminal phrase where too it only changed con-
tinuously? The latter alternative constitutes the hypothesis of
subconsciousness.

According to this hypothesis the total field with which we
began is divided into two parts by what Fechner emphatically
called "the fact of the threshold," and the term field of con-
sciousness is henceforth restricted to that part within which the
focus of consciousness always lies, the outlying part being the
region of subconsciousness. Difficulties now begin to be
apparent. The intensity or vividness of a presentation within
the field of consciousness depends partly on what we may call
its inherent or absolute intensity, partly on the attention that
it receives; but this does not hold of presentations in subcon-
sciousness. These sub-presentations, as we ought perhaps to
call them, cannot be severally and selectively attended to,
cannot be singled out as direct objects of experience. Many psych-
ologists have accordingly maintained not only that they cannot
with propriety be called presentations, but that they have no
strictly psychical existence at all. This, however, is too extreme
a view. If nothing of a presentational character can exist
save in the field of consciousness as thus circumscribed by a
definite boundary or threshold, a breach of continuity is implied
such as we nowhere else experience: even the field of sight,
from which the metaphor of a field of consciousness is derived,
has no such definite margin. The threshold then is not compa-
able to a mathematical line on opposite sides of which there
is an intensive discontinuity. This has been amply proved
by the psychophysical investigations of Fechner and others.
We listen, say, to a certain sound as it steadily diminishes; at
length we cease to hear it. Again, we listen for this same sound
as it steadily increases and presently just barely hear it. In
general it is found that its intensity in the former case is
less than it is in the latter, and there is also in both cases a certain
margin of doubt between clear presence and clear absence; the
presentation seems to flicker in and out, now there and now
gone. Further, in comparing differences in sensations—of
weight, brightness, temperature, &c.—we may fail wholly to
detect the difference between \(a\) and \(b\), \(b\) and \(c\), and yet the
difference between \(a\) and \(c\) may be clearly perceived. We have
thus to recognize the existence of a difference between sensa-
tions, although there is no so-called "sensation of difference."

But if this much continuity must be admitted we can hardly
fail to admit more. If differences of presentation exist within
the field of consciousness beyond the outermost verge of the
"threshold of difference," we cannot consistently deny the
existence of any presentations at all beyond the threshold
of consciousness. Since the field of consciousness varies greatly and
often suddenly with the amount and distribution of attention,
we must, as already said, either recognize such subconscious
presentations or suppose that clearly differentiated presenta-
tions, presentations that is to say of finite intensity, pass
abruptly into or out of existence with every such variation of the
field.

The hypothesis of subconsciousness, then, is in the main
nothing more than the application to the facts of presenta-
tion of the law of continuity, its introduction into psychology being
due to Leibnitz, who first formulated that law. Half the diffi-
culties in the way of its acceptance are due to our faulty ter-
minology. With Leibnitz consciousness was not coextensive
with all psychical life, but only with certain higher phases of it.

1 Of late, however, the tendency has been to make con-
sciousness cover all stages of mental development, and all grades
of presentation, so that a presentation of which there is no con-
sciousness resolves itself into the manifest contradiction of an
unpresented presentation—a contradiction not involved in
Leibnitz's "unappercieved perception." But such is not the
meaning intended when it is said, for example, that a soldier in
battle is often unconscious of his wounds or a scholar unconscious
of the application in which he has been indulging. All about him
are the recesses of his mind. There would be no point in saying
a subject is not conscious of what is not presented at all; but to say
that what is presented lacks the intensity requisite in the given
distribution of attention to change that distribution appreciable
is pertinent enough. Subconscious presentations may tell on
conscious life—as sunshine or mist tells on a landscape, or the
underlying writing on a palimpsest—although lacking either the
intensity or the individual distinctness requisite to make
them definite features. Even if there were no facts to warrant

\(1\) The following brief passage from his \textit{Principes de la nature et de la}
\textit{grace} (A) shows his meaning: "Il est bon de faire distinction
entre la \textit{Perception}, qui est l'état intérieur de la \textit{Mondale}
représentant les choses externes, et l'\textit{Appréciation}, qui est la \textit{Conscience},
ou la conscience réflexive de cet état intérieur, laquelle n'est point
donnée à toutes les âmes, ni toujours à la même âme. Et c'est faute
de cette distinction que les \textit{Cartésiens} ont manqué, en comptant
pour rien les perceptions dont on ne s'appercoit pas, comme le peuple
compte pour rien les corps insensibles" (\textit{Op. Phil. Erdmann's ed.},
p. 719).
this concept of an ultra-liminal presentation of impressions it
might still claim an a-priori justification.
The subjective presentation of ideas as distinct from impressions
calls, however, for some special consideration. As we
can turn our attention to the sensory threshold
and await the entrance of an expected impression,
so we may await the emergence of a "memory-
image"; and again the threshold turns out to be not a mathemati-

cally exact boundary but a region of varying degree.\footnote{1}
What we are trying to recollect seems first to waver, now at the tip of
our tongue and the next moment completely gone, then perhaps
a moment afterwards rising into clear consciousness. Sometimes when asked,
say, for the name of a certain college contemporary we reply: I cannot tell, but I should know the
name if I heard it. We are aware that we could "recognize,"
though we cannot " reproduce." At other times we are con-
fident that even recognition is no longer possible, and still if
we meet the man himself in the old scenes and heard his voice his
name might yet recur. Nevertheless, it may be urged, it is
surely incredible that all the incidents of a long lifetime and all
the hums of knowledge in a wandering mind that may possibly recur—
the infinitely greater part of our spiritual treasures,"
as Hamilton says—are separately retained and continuously pre-

COt\pent in the form and order in which they were originally
experienced or acquired. This, however, is not implied. Images
in contrast to impressions have always a certain generality.
The same image may figure in very various connexions, as may
the name letter, for example, in many words, the same word in
many sentences. We cannot measure the literature of a language
by its vocabulary, nor may we equate the extent of our " spiritual

Theodore's" when these are successively unfolded with the
psychical apparatus, so to say, in which they are subconsciously
involved.\footnote{2} Take the first book of the Aeimis, which, as Macaulay
would say, every schoolboy knows: as subconsciously involved,
when the boy is not thinking of it, his knowledge is more com-
parable to a concordance than to the text itself, which never-
theless can be reproduced from it. In the text Aeneas occurs
many times, in the concordance as a heading but once. But
give him the cue Aeneas scopolum, and the boy reeds off from the
186th line; or Prastae Aeneas, and he starts with the 220th.
But ask him for the 580th line; he is probably helpless, while
a dunci with the book in his hand can read it off at once. Say
instead Et pater Aeneas, and the boy can straithcomple-
the line while the dunci is now helpless. So though its
explicit revival is successional, occurs, so to say, in single file,
a whole scheme in which many ideas are involved may rise

towards the threshold together. When our schoolboy, for
example, turns from classics to geography, the mention of
Abyos, which might then have recalled a Titan, now leads him
to think only of his book of maps. And there is a like sudden
shifting of the substratum of our thoughts, when, taking up the
manual paper, we glance first at the foreign languages, then at
the money market, and then at the doings of our political
friends. Yet more remote than all, obscurer but more per-
vasive, like the clouds of cherubims and imps vaguely limned
minds is the framework of the conscious mental atmosphere, "gay notes that people the sunbeams
of our cheerfulness and make all couleur de rose, or "horrid
shapes and sights unholy" that overcast the outlook when we
"have the blues." And as attention relaxes, these advance into the
foreground and become more or less palpable hopes or fears.

\footnote{1} Herbert and Fechner describe subconcious presentations generally
as existing below the threshold. On the other hand, we have
spoken of subconcious sensations as existing beyond it. In view of
the important differences between the two forms of presentations
primary and secondary, this distinction of ultra-liminal and sub-
liminal presentations is well considered and justifiable.

\footnote{2} This doctrine of the involution and evolution of ideas we owe
to Leibnitz. Herbert attempted in a very arbitrary and a priori
fashion to develop it into a physical statics and dynamics with the
result—usual to extreme views—that later psychologists neglected
it altogether. There are now signs of a fresh reaction, and we shall
continually come across evidence of the wide range and great impor-
tance of the doctrine as we proceed.

Because of the manifold forms into which they may evolve,
subconcious images, while still involved, are sometimes called
"psychical" or more definitely "presentational dispositions."
The word disposition means primarily an arrangement, as when
we talk of the disposition of troops in a battle or of cards in a
game; the disposition, that is to say, is always something
actual. Which of several potential dispositions they will actually
assume will depend upon circumstances, but at least, as Leibnitz
long ago maintained, "les puissances véritables ne sont jamais
des simples possibilités." What is requisite to the realization
of a given potentiality is sometimes a condition to be added,
sometimes it is one to be taken away. A locomotive with the
fire out has no tendency to move, but with steam up it is only
hindered from moving by the closure of the throttle-valve or
the friction of the brake. Now presentational dispositions we
assume to be of the latter sort. They are processes or functions
more or less inhibited, and the inhibition is determined by their
relation to other psychical processes or functions. The analysis
and genesis of these presentational interactions will occupy us
at length by and by; it may then be possible to explain the
gradual involution of what was successively unfolded in-
explict consciousness into those combinations which Herbert

called "apperception-masses," combinations devoid of the con-
crete hints of date and place which are essential to memory.
Meanwhile the evidence added—decidedly cogent though
admittedly indirect—together with the difficulties besetting
the extreme view that beyond or below the threshold of con-
sciousness there is nothing presentational, seems clearly to
justify the hypothesis of subconciousness. At the same time
the principle of continuity, everywhere of fundamental im-
portance when we are dealing with reality, forbids the attempt
arbitrarily to assign any limits to the subconcious.
Many psychologists have proposed to explain subconcious
retention by habit. But it is obvious that habit itself implies
retention and is practically synonymous with disposition; it
must therefore presuppose disposition if we are to escape the
absurdities of puissances ou facultés non, with which in this very
moment Leibnitz twitted Locke. Yet, obvious as all this may be, it is frequently ignored even by those who are fond
of exposing the pretended explanations of the "faculty-psycholo-
gists" and quoting Molière to confute them. Thus we find
J. S. Mill arguing: "I have the power to walk across the room
though I am sitting in my chair: we should hardly call this
power a latent act of walking."\footnote{3} Nor should we call it a power
at all if Mill had been paralysed, or if, instead of sitting in his
chair, he had been lying in his cradle. What we want is the
simplest psychological description of the situation after the
power has been acquired by practice and is still retained. In
such a case we can be conscious of the "idea" of the move-
ment without the movement actually ensuing; yet only in such
wise that the idea is more apt to pass over into action the
intenser it is, and often actually passes over in spite of us. Surely
there must be some functional activity answering to this con-
scious presentation; why not a much less amount of it be
conceived possible in subconcious presentation?

\footnote{3} Examination of Sir W. Hamilton's Philosophy, 3rd ed., p. 329.

For a detailed account of the various sensations and perceptions
pertaining to the several senses the reader is referred to the articles
VISION; HEARING; TOUCH; TASTE; SMELL, &c.

\footnote{4} Senses and Intellect, 4th ed. (1894), p. 101.}
or what the more careful of them call irritability; and, true again, that this irritability is invariably preceded by a physical process called stimulation. But it may be asked, why not recognize a connexion that actually obtains, since otherwise sensation must remain unexplained? Well, in the first place, such "psychophysical" connexion is not a psychological explanation: it cannot be turned directly to account in psychology, either analytic or genetic. Next the psychological fact called sensation always is, and at bottom always must be, independently ascertained; for the physiological "neurosis" or irritation has not necessarily a concomitant "psychosis" or sensation and, strictly dealt with, affords no hint of such. Finally, this inexplicability of sensation is a psychological fact of the utmost moment; it answers to what we call reaity in the primary sense of the term. The psychophysicist, in setting out to explain sensation, has—unawares to himself—left this fundamental reality behind him. For it belongs essentially to individual experience, and this—in assuming the physical standpoint—he has of course transcended. Nevertheless the mistake of method that here reveals itself was perhaps inevitable, for the facts of another's sense-organs and their physical excitants must have obscured themselves on observation long before the reflective attitude was advanced enough to make strictly psychical analysis possible. The psychophysical standpoint, that is to say, was attained before the purely psychological; and the consequent bias is only now in process of correction. A series of physical processes, first without and then within the organism—etherial or aerial vibrations, neural and cerebral excitations—was the starting-point. What comes first, immediately, and alone, in the individual's experience, and is there simply and positively real, was then misinterpreted as subjective modification, mental impression, species sensibilis, or the like. For from the days of Democritus to our own the same crude metaphor has prevailed without essential variation. And here the saying holds: Vestigia nulla retrorsum. Into the man's head the whole world goes, including the head itself. Such thoroughgoing "introspection" affords no ground for subsequent "projection." But the endeavour to explain sensation overreaches itself: the external object or thing that was supposed to cause sensations and to be therefore distinct from them, was in the end wholly resolved into these and regarded as built out of them by association (Mill) or by apperceptive synthesis (Kant). But no "mental chemistry," no initial alchemy of "forms," can generate subjective reality from feelings or sense-impressions psychologically defined. A's experience as it is for B is not real but inferential; and if the grounds of the inference, which are the only realities for B, are to be regarded as the causes of which A's experiences are merely the effects, then the two experiences are on a wholly different footing. When A treats B in the same fashion we get the world in duplicate: (1) as original and outside, i.e. as cause, and (2) as copied within each percipient's head, i.e. as effect. But when B interprets his own experience as he had interpreted A's we seem to have lost the real world altogether. In presence of this dilemma, the philosophers of our time, as already said, are feeling it needful to revise their psychology. The question of method is vital. If the psycho-physical standpoint were the more fundamental, psychology would be based on physiology, and the old definition of sensation might stand. If, on the other hand, it is the exclusive business of psychology to analyse and trace the development of individual experience as it is for the experiencing individual, then—however much neurological evidence may be employed as a means of ascertaining psychological facts—the facts themselves must be scrupulously divested of all physical implications, the psychophysical method takes a secondary place, and the objective reality of "sensory" presentations stands unimpeached.

The duality of subject and object in experience compels us also to object to the description of sensations as "states of conscious-ness." Since it is the subject, not the object that is conscious, the term state of consciousness implies strictly a subjective reference; and so it is only applicable to sensations, if they are regarded as subjective modifications, either affective or active. The former would identify sensation with feeling, and this—for reasons already given—we must disallow. But in the case of presentation, implies the subjective activity we call attention; it is not, however, a modification or state of this activity, but the object of it. This relation is expressed in German by means of the distinct terms of Völkerpsychologie and in the present case of Empfinden and Empfindung; and German psychology has gained in clearness in consequence. The distinction of conception and concept (concretum) is to be found in older English writers and was recently taken up by Sir W. Hamilton, who regards all expression of the objective distinction of perception and concept. It would be a great gain if there were a corresponding pair of terms to distinguish between the sensation act and the object "sensed," as some have been doing to say. Reception and perception are apart and seem unexceptionable—apart, of course, from their novelty. If, we are to rest content with our present untechnical terminology we must understand sensations to mean objective changes as they first break in upon the experience of our psychological individual; in this respect Locke's term "impression" has a certain appropriateness.

What we ordinarily call a single sensation has not only a characteristic quality but it is also quantitatively determined in respect of intensity, protensity (or duration) and extent. A plurality of properties, it may be said, straightforwardly implies complexity of some sort. This is obvious and un- *character*-deniable; psychological—as distinct from psychical—*instincts of Sensation*.—analysis of simple sensations is possible, and the description just given is reached by means of it. Such analysis, however, presupposes the comparison of many sensations; but to the complexity it discloses there is no answering plurality discernible in the immediate experience of a single sensation. To make this clearer let us start from a case in which such plurality can be directly verified. In a handful of rose petals we are aware at once of a definite colour, a definite odour and a definite "feel." Here there is a plurality (a+b+c), any part of which can be withdrawn from our immediate experience without prejudice to the rest, for we can close the eyes, hold the nose, or drop the petals on the table. Let us now turn to the colour alone; this we say has a certain quality, intensity, extensity, &c. But not only have we not one sense for intensity, another for intensity, &c., but we cannot reduce the intensity to zero and yet have the quality remaining; nor can we suppress the quality and still retain the intensity. In this case then what we have is not a plurality of presentations (a+b+c), but a single presentation having a plurality of attributes (a b c) so related that the absence of any one annihilates the whole. But, though as already said, such single presentation gives, as it stands, no evidence of this plurality, yet it is to be remembered that in actual experience we do not deal with sensations in isolation; here, accordingly, we find evidence in plenty to justify our psychological analysis. In innumerable cases we experience varieties of intensity with little or no apparent change of quality, as happens, for example, when a sounding pitch-pipe is moved towards or away from the ear; and continuous changes of quality without any change of intensity, as happens when the pipe is shortened or lengthened without any alteration of position. We may have tactual or visual sensations which vary greatly in extensity without any striking change of quality, and we may have such sensations in every possible variety of quality without any changes of extensity.

The numerous and striking diversities among our present sensations are obviously not primordial; what account then can we give of their gradual differentiation? Some psychologists have assumed the existence of absolute "units of sensation");[1] Reception does not in English suggest the taking back of the Latin recipere; it expresses only the comparative passivity of sense. In contrast to percipere (to take entire possession of) it implies the absence of that assimilation which is essential to perception; and finally it contrasts appropriately with retention.

1 This distinction, though continually overlooked, is vitally important. By psychological analysis we mean such analysis as the psychological observer can reflectively make, by psychical analysis only such analysis as is possible in the immediate experience of the subject observed.

---

1 Nothing shows this more plainly than the newly-coined term episphenomenon now applied in this connexion
sensibility," all identically the same, and explain the unlikeliness of our existing sensations as resulting "from unlike modes of integration of these absolute units."

The sole evidence on which they rely is physiological, the supposed existence of a single nerve shock or neural tremor. It is true that in an extirpated nerve what is known as the "negative variation" is approximately such an isolated event of uniform quality. But the same cannot be said of what happens during the stimulation of a nerve in situ with its peripheral and central connexions still intact. The only evidence apparently to which we can safely appeal in this inquiry is that furnished by biology. Protoplasm, the so-called "physical basis of life," is amenable to stimulation by every form of physical agency—chemical, mechanical, thermal, electrical—with the single exception of magnetism; and in keeping with this it is found that unicellular organisms respond; and respond in ways more or less peculiar, to each of these possible modes of excitation. Since, so far as is known, there is no morphological separation of function in these lowest forms of life, it is reasonably assumed that the single cell acts the part of "universal sense-organ," and that the advance to such complete differentiation of sense-organs as we find among the higher vertebrates has been a gradual advance. Numerous facts can now be adduced of the occurrence of "transitional" or "alternating" sense-organs among the lower forms of multicellular animals; organs, that is to say, which are normally responsive to two or more kinds of stimulus, and thus hold an intermediate position between the universal sense-organ of the Protozoa and the special sense-organ of the Mammalia. For example, a group of cells which would behave toward all stimuli impartially were they independent unicellular organisms become, as an organ in a multucellular organism, amenable only to mechanical or only to chemical stimuli,—become, that is to say, an organ of touch and of hearing, or an organ of taste and also of smell; until, finally, when differentiation is sufficiently advanced, the group ends by becoming exclusively the organ of one specified sense, touch or hearing in the one case, taste or smell in the other. Of course the imperfectly specialized sensations, say of the leech, and still more the wholly un specialized sensations of the amoeba, cannot be regarded as blends of some or all of those which we are said to receive through our five senses. We must rather suppose that sensations at the outset corresponded very closely with the general vital action of stimuli as distinct from their action on specially differentiated sensory apparatus. Even now we are still aware of the general effects of light, heat, fresh air, food, &c., as invigorating or depressing quite apart from their specific qualities. Hence the frequent use of the term general or common sensibility (coemthesis). But, though less definitely discriminated, the earlier, and what we call the lower, sensations are not any less concrete than the later and higher. They have been called general rather than specific, not because psychologically they lack any essential characteristic of sensation which those acquired later possess, but simply because physiologically they are not, like these, correlated to special sense-organs.

But, short of resolving such sensations into combinations of one primordial modification of consciousness, if we could conceive such, there are many interesting facts which point clearly to a complexity that we can seldom directly detect. Several of our supposed sensations of taste, e.g., are complicated with sensations of touch and smell: thus the pungency of pepper and the dryness of wine are tactual sensations, and their spicy flavours are really smells. How, relegated to one province or mingle with the other, the simple tastes are first brought home to us by a severe cold in the head, as this temporarily prevents the access of exhalations to the olfactory surfaces. The difference between the smooth feel of a polished surface and the roughness of one that is unpolished, though to direct introspection an irreducible difference of quality, is probably due to the fact that several nerve- terminations are excited in each case: where the sensation is one of smoothness all are stimulated equally; where it is one of roughness the ridges compress the nerve-ends more, and the hollows compress them less, than the level parts do. The most striking instance in point, however, is furnished by the differences in musical sounds, to which the name timbre is given. To the inattentive or un instructed ear notes of "compound tones" appear to be only qualitatively diverse and not to be complexes of simple tones. Yet it is possible with attention and practice to distinguish these partial tones in a note produced on one instrument, a horn, say, and to recognize that they are different from those of the same note produced on a different instrument, for example, a violin.

In like manner many persons believe that they can discriminate in certain colours, hence called "mixed," the elementary colours of which they are held to be composed; red and yellow, for example, in orange, or blue and red in violet. But in so thinking they appear to be misled, partly by the resemblance that certainly exists between orange and red, on the one hand, and orange and yellow on the other, the two colours between which in the colour spectrum it invariably stands; and partly by the knowledge that, as a pigment, orange is obtainable by the mixture of red and white pigments; and so in the case of sensory continua a seeming discreteness on the part of the perceiving person is replaced by a seeming completeness on the part of the sensation. In these cases the confusion is one of kind, that is, of comparing like by like; for what is commonly called "the absence of any sensory difference" can be a consequence of the whole absence of any sensation in one case, and may be due to a partial sensation in another, and is thus a question of relative variety or coarseness of sensibility rather than separation of units. Thus, the ground-tone of a clang-complex has not only a greater intensity but also a greater extensity than any of the over-tones. There is also in such cases a certain rivalry or antagonism between the complex as an unanalysed whole and the component parts as analysed, and even between the several partial sensations after such analyses. In the absence of such direct evidence it is unwar rantable to infer psychological complexity from complexity in the physical stimulus, even when this is really present. In the case of pigment mixture, however, there is no such physical complexity as is vulgarly supposed. And it is worth noting that white light is physically the most complex of all, whereas the answering sensation is not only simple but probably the most primitive of all visual sensations.

Every sensation within the fields of consciousness has sensibly some continuous duration and seems sensibly to admit of some continuous variation in intensity and extensity. But when we consider the rate at which sensations of presentational change is more than apparent has been questioned. Sensations of almost liminal intensity are found to fluctuate every few seconds, and, as already remarked, when the threshold of intensity is actually reached, they seem intermittently to appear and disappear, a fact which Hume long ago did not fail to notice. The results of numerous experiments, however, justify the conclusion that these variations are due primarily to oscillation of attention, and furnish so far no ground for the assumption that even the liminal sensation is discontinuous. But again we can only detect a difference of intensity when this is of finite amount and bears a certain constant ratio to the initial intensity with which it is compared—a fact commonly known as Weber’s Law. But this imperfection in our power of discrimination is no proof that our sensations, when once discriminated, are incapable of discrimination; it is positive evidence in favour of such discontinuity, but it is altogether improbable on general grounds. Lastly, there is always more or less distinctness in the several nerve-endings as well as isolation of the nerve-fibres themselves. The skin, for example, when carefully explored, turns out to be a complex mosaic of so-called “spots,” severally responding to stimulation by sensations of pressure, heat, cold, and pain. But from this to argue that the extensity of a sensation is really a mere aggregate without any continuity is on a par with calling a lake a

3 Cf. Stumpf, Temppsychologie, i, 58 seq.
collection of pools because it is fed by separate streams. If it could be shown that in the brain as a whole there is no functional continuity a formidable psychophysical problem would have no doubt arise.

As regards the quality of sensations—the primitive sensation of light appears to consist only of the single quality we call "light," a quality which ranges in intensity from a dazzling brightness that becomes painful and blinding down to a zero of complete darkness; a limit which, however, is never completely attained, since the retina is always more or less internally stimulated—hence what is called the eye's own light (Eigenlicht). The first responses to light-stimulation seem to be very much on a par with our own to diffused heat or cold; some organisms seek the light and others shun it. As little as our temperature-sense yields us a perception of form does the light-sense at this level yield any. Not until we are able to distinguish between successive taps on the retina has any discrimination of form is possible, do black and white attain the meaning they now have for us. An object can be visually perceived only when its colour or shade differs from that of the surrounding field; so far black as a "secondary quality" is on a par with colour, that is to say, when we are talking of things it may be called a quality. But there is still an important difference; in a light field many colours or shades may be distinguished, but in a dark field none. Though it is correct to speak of perceiving a black object, must we not then maintain that—as far as it is really black—the object yields us directly no sensation? Similarly, the piper is said to "feel" the holes in his whistle when actually he only touches the solid metal in which they are pierced; or the soldier is said to hear the tattoo, though he has no auditory sensation or sensation intervening between successive taps on the drum. And it has yet to be shown that there is any more justification for speaking of visual sensations without luminosity. Meanwhile we must maintain that in absolute darkness we do not see black, since we do not see at all. No doubt we are prone to identify the two concepts darkness and blackness, for what we may call their sensory content is the same, viz. the absence of visual sensation.

Whereas in nature the only diffused light we need consider is that emitted by the sun, the rays transmitted by the things we vary in physical quality and in their effects upon protoplasm. As soon, therefore, as visual forms can be distinguished, a differentiation among light-sensations becomes obviously advantageous. The first colours to be differentiated were probably yellow and blue, or perhaps it would be better to say, "warm" colour and "cold" colour, upon which there followed a further differentiation of the warm colour into red and green. It is interesting to note that all possible sensations of colour can be specified by a sphere, in which (a) the maximum of luminosity is at one pole, and the minimum at the other; (b) the sphere is divided into two equal parts; and (c) the amount of saturation (or absence of white) for any given zone of illumination increases with distance from the axis.

In dealing with the quality of auditory sensations we have to distinguish between the simple sensations called tones and the sensation-complexes, either clangs or noises, which result from their combination. Simple tones also constitute a qualitative continuum, but it has only one dimension, their so-called "pitch"; this may be represented by a straight line ranging between two more or less indefinite extremes. If intensity, that is to say loudness, is taken into account, we have of course a continuum of two dimensions. The tone-continuum is also universally regarded as steadily diminishing in mass and complexity as we ascend, in the same way that the lower limit, the so-called deep or grave tones become less "even," till at length distinct, more or less pervasive, tremors are felt rather than heard as distinct impulses on the ear-drum. The so-called high or acute tones again, as we approach their limit, are accompanied by tactual, often more or less painful, sensations, as if the ear were pierced by a fine needle. This connexion of auditory with tactual sensations confirms the independent evidence of biology pointing to an original differentiation of sound from touch. The special characteristics of tone-complexes, whether clangs or noises, are due to the remarkable analytic power which belongs to the sense of hearing. Two colours cannot be simultaneously presented unless they are differently localized, but several tones may form one complex whole within which they, as "partial" tones, are distinguishable, though spatially undifferentiated.

Unlike the higher senses of sight and hearing, the lower senses of touch, taste, smell, &c., do not constitute qualitative continuum. Temperatures may indeed be represented as ranging in opposite directions, i.e. through heat or through cold, between a zero of no sensation and the organic sensations due to the destructive action of both extremes, heat and cold alike. But the continuity in this case is intensive rather than qualitative. Tastes fall into the four isolated qualities known as sweet, sour, bitter, saline; but smells hardly admit of classification at all. Sensations of touch and sight have in a pre-eminent degree a certain peculiar continuity which differentiation of extensity entail, and which we shall have presently to consider further under the title of local signs. The various sensations classed together as organic, hunger, thirst, physical pain, &c., are left to the physiologist to describe.

Our motor presentations contrast with the sensory by their want of striking qualitative differences. They are divided into two groups: (a) motor presentations proper and (b) auxilio-motor of kinaesthetic presentations. The former answer to our "feelings of muscular effort" or "feelings of innervation." The latter are those presentations due to the straining of tendons, stretching and flexing of the skin, and the like, by which the healthy man knows that his efforts to move are followed by movement, and so knows the position of his body and limbs. It is owing to the absence of these presentations that the anaesthetic patient cannot directly tell whether his efforts are effectual or not, nor in what position his limbs have been placed by movements from without. Thus under normal circumstances motor presentations are always accompanied by auxilio-motor; but in disease and in passive movements they are separated and their distinctness thus manifest. Of course, we may suppose kinesthetic presentations to have formed one of the differentiated intuitions of the primitive continuum, but now, with as sensations, they have become a collection of special continua, viz. the groups of movements possible to each limb and certain combinations of these movements.

But whereas kinaesthetic presentations were commonly allowed to be purely sensory, the concomitants of centripetal excitations—hence the older name of "muscular or sixth sense"—applied to them by Bell, James, Ferrier, and others—concerning motor presentations proper, a very different view, first tentatively advanced by the great physiologist Johannes Müller, and adopted by Helmholtz, Wundt, and especially by Bain, long progressive. It is that actions are generally undifferentiated, and if not completely overcome. According to this view, "the characteristic feeling of exerted force" must be regarded, Bain maintained, "not as arising from an inward transmission... but as the concomitant of the outgoing current by which the muscles are stimulated to act... (op. cit. p. 79). The necessity for this assumption has certainly not been established on physiological grounds, nor apparently did Bain rely primarily on these; for at the very outset of his discussion we find him saying: "It is clear... (op. cit. p. 59). But this important psychological truth is affirmed as strenuously by some, at any rate (e.g. Professor James) of Bain's opponents as it was by Bain himself. Unhappily many, under the same psychophysical...
PSYCHOLOGY

[PERCEPTION]

bias and so induced, like the upholders of this innervation theory, to look for evidence of subjective activity in the wrong place, have been led to doubt or to deny the reality of this activity altogether. In fact, this theory, while it lasted, tended to maintain an undue separability of so-called "sensory" from so-called "motor" presentations, as if living experience were literally an alternation of two independent states, one wholly passive and the other wholly active, corresponding to the anatomical distinction of organs of sense and organs of movement. The subject of experience or Ego does not pass to and fro between a sensorium commune or intelligence department and a motorium commune or executive, is not in successive intervals receptive and active, still less always passive, but rather always actively en rapport with an active Non-Ego, commonly called the External World.

Perception.

17. In treating apart of the differentiation of our sensory and motor continua, as resulting merely in a number of distinguisable sensations and movements, we have been compelled by the exigencies of exposition to leave out of sight another process which really advances pari passu with this differentiation, viz. the integration or synthesis of these proximately elementary presentations into those complex presentations which are called percepts, intuitions, sensi-motor reactions and the like. It is, of course, not to be supposed that in the evolution of mind any creature attained to such variety of distinct sensations and movements as a human being possesses without making even the first step towards building up this material into the most rudimentary knowledge and action. On the contrary, there is every reason to think, as has been said already incidentally, that further differentiation was helped by previous integration, that perception prepared the way for distinct sensations, and purposive action for more various movements. This process of synthesis, which is in the truest sense a psychical process, deserves some general consideration before we proceed to the several complexes that result from it.

Most complexes, certainly the most important, are consequences of that principle of subjective selection whereby interesting sensations lead through the intervention of feeling to movements; and the movements that turn out to subsist such interest come to have a share in it. In this way—which we need not to examine more closely now—it happens that a certain sensation, comparatively intense, and a certain movement, definite enough to control that sensation, engage attention, to the more or less complete exclusion of the other less intense sensations and more diffused movements that accompany them. Apart from this intervention of controlling movements, the presentation-continuum, however much differentiated, would remain for all purposes of knowledge little better than the disconnected chartfold for which Kant took it. At the same time, it is to be remembered that the subject obtains command of particular movements out of all the mass involved in emotional expression only because such movements prove on occurrence adapted to control certain sensations. A long process, in which natural selection probably played the chief part at the outset—subjective selection becoming more prominent as the process advanced—must have been necessary to secure as much purposive movement as even a worm displays. We must look to subjective interest to explain, so far as psychological explanation is possible, those syntheses of motor and sensory presentations which we call spatial perception and the intuitions of material things. For example, some of the earliest lessons of this kind seem to be acquired as we may presently see, in the process of exploring the body by means of the limbs,—such a presentation of any groups in subjective interest can obviously never be wanting.

Perception sometimes means only the recognition of a sensation or movement as distinct from its original presentation, thus implying the more or less definite retention of certain residua of past experience which resembled the present. More frequently it is used as the equivalent of what has been otherwise called the "localization and projection" of sensations—that is to say, of sensations apprehended either as affections of some part of our own body regarded as extended or as states of some foreign body beyond it. According to a former usage, strictly taken, there might be perception without any spatial presentation at all; a sensation that had been attended to a few times might be perceived as familiar. According to the latter, an entirely new sensation, provided it were complicated with motor experiences in the way required for its localization or projection, would be perceived. But as a matter of fact actual perception probably invariably includes both cases; impressions which we recognize we also localize or project, and impressions which are localized or projected are never entirely new—they are, at least, perceived as sounds or colours or aches, &c. It will, however, frequently happen that we are specially concerned with only one side of the whole process, as is the case with a teataster or a colour-mixer on the one hand, or, on the other, with the patient who is perplexed to decide whether what he sees and hears is "subjective," or whether it is "real." But there is still a distinction called for: perception as we now know it involves not only recognition (or assimilation) and localization, or "spatial reference," as it is not very happily termed, but it usually involves "objective reference" as well. We may perceive sound or light without any presentation of that which sounds or shines; but none the less we do not regard such sound or light as merely the object of our attention, as having only immanent existence, but as the quality or change or state of a thing, an object distinct not only from the subject attending but from all presentations whatever to which it attends. Here again the actual separation is impossible, because this factor in perception has been so intertwined throughout our mental development with the other two. Still a careful psychological analysis will show that such "reification," as we might almost call it, has depended on special circumstances, which we can at any rate conceive absent. These special circumstances are briefly the constant conjunctions and successions of impressions, for which psychology can give no reason, and the constant movements to which they prompt. Thus we receive together, e.g. those impressions we now recognize as severally the scent, colour, and "feel" of the rose we pluck and handle. We might call each a "percept," and the whole a "complex percept." But there is more in such a complex than a sum of partial percepts; there is the apprehension or intuition of the rose as a thing having this scent, colour and texture. We have, then, under perception to consider (a) the recognition and (b) the localization of impressions, and (c) the intuition of things.

18. The range of the terms recognition or assimilation of impressions is wide: between the simplest mental process they may be supposed to denote and the most complex Assimilation.

Assimilation—there is a great difference. The penguin that is watched unmoved the first landing of man upon its impressions, lonely rock becomes as wild and wary as more civilized fowl after two or three visits from its molester: it then recognizes that featherless biped. His friends at home also recognize him though altered by years of peril and exposure. In the latter case some trick of voice or manner, some "striking" feature, calls up and sustains a crowd of memories of the traveller in the past—events leading on to the present scene. The two recognitions are widely different, and it is from states of mind more like the latter than the former that psychologists have usually drawn their description of perception. At the outset, they say, we have a primary presentation or impression P, and after sundry repetitions there remains a mass or a series of P residua, P1P2 P3...; perception ensues when, sooner or later, a P is presented that is the same as a P residua—representation or ideas. Much of our later perception, and especially when we are at all interested, awakens, no doubt, both distinct memories and distinct expectations; but, since these imply previous perceptions, it is obvious that the earliest form of recognition, or, as we might better call it, assimilation, must be free from such complications, can have nothing in it answering to the overt judgment, P1, is a P. Assimilation involves re-entiveness and differentiation, as we have seen, and prepares the way for re-presentation; but in itself there is no confronting

[meaning of perception]
the new with the old, no determination of likeness, and no subsequent classification. The pure sensation we may regard as a psychological myth; and the simple image, or such sensation revived, seems equally mythical, as we may see later on. The nth sensation is not like the first: it is a change in a presentation-continuum that has itself been changed by those preceding; and it cannot with any propriety be said to reproduce these past sensations, for they never had the individuality which such reproduction implies. Nor does it associate with images like itself, since where there is association there must first have been distinctness, and what can be associated can also, for some good time at least, be dissociated.

19. To treat of the localization of impressions is really to give an account of the steps by which the psychological individual comes to a knowledge of space. At the outset of such an inquiry it seems desirable first of all to make plain what lies within our purview, and what does not, lest we disturb the peace of those who, confounding philosophy and psychology, are ever eager to fight for or against the a priori character of this element of knowledge. That space is a priori in the epistemological sense it is no concern of the psychologist either to assert or to deny. Psychologically a priori or original in such sense that it has been either actually or potentially an element in all presentation from the very beginning it certainly is not. It will help to make this matter clearer if we distinguish what philosophers frequently confuse, viz. the concrete spatial experiences, constituting actual localization for the individual, and the abstract concept of space, generalized from what is found to be common in such experiences. A gannet's mind "possessed of" a philosopher, if such a conceit may be allowed, would certainly afford its tenant very different spatial experiences from those he might share if he took up his quarters in a mole. No, any one who has revisited after years a place from which he had been absent since childhood knows how largely a "personal equation," as it were, enters into his spatial perceptions. Or the same truth may be brought home to him if, walking with a friend more athletic than himself, they come upon a ditch, which both know to be twelve feet wide, but whereas the one feels he can clear by a jump the other feels he cannot. In the concrete "up" is much more than a different direction from "along." The hen-harrier, which cannot soar, is indifferent to a quarry a hundred feet above it—to which the peregrine, built for soaring, would at once give chase—but is on the alert as soon as it descends prey of the same apparent magnitude, but upon the ground. Similarly, in the concrete, the body is the origin or datum to which all positions are referred, and such positions differ not merely quantitatively but qualitatively. Moreover, our various bodily movements and their combinations constitute a network of co-ordinates, qualitatively distinguishable but geometrically, so to put it, both redundant and incomplete. It is a long way from these facts of perception, which the brutes share with us, to that scientific concept of space as having three dimensions and no qualitative differences which we have elaborated by the aid of thought and language, and which reason may see to be the logical presupposition of what in the order of mental development has chronologically preceded it. That the experience of space is not psychologically original seems obvious—quite apart from any successful explanation of its origin—from the mere consideration of its complexity. Thus we must have a plurality of objects—A out of B, B beside C, distant from D, and so on; and these relations of externality, juxtaposition, and size or distance imply further specialization; for with a mere plurality of objects we have not straightforward spatial differences. Juxtaposition, e.g., is only possible when the related objects form a continuum; but, again, not any continuity is extensive. Now how has this complexity come about?

The first condition of spatial experience seems to lie in what has been noted above (§ 11) as the extensity of sensation. This quality, not even if motor presentations are added, will account for this space-element in our perceptions. A series of touches a, b, c, d may be combined with a series of movements m1, m2, m3, m4; both series may be reversed; and finally the touches may be presented simultaneously. In this way we can attain the knowledge of the coexistence of objects that have a certain quasi-distance between them, and such experience is an important element in our perception of space; but it is not the whole of it. For, as has been already remarked by critics of the associationist psychology, we have an experience very similar to this in singing and hearing musical notes or the chromatic scale. The most elaborate attempt to get extensity out of succession and coexistence is that of Herbert Spencer. He has done, perhaps, all that can be done, and only to make it the more plain that the entire procedure is a θυτερων πρότερων. We do not first experience a succession of touches or of retinal excitations by means of movements, and then, when these impressions are simultaneously presented, regard them as extensive, because they are associated with or symbolize the original series of movements; but, before and apart from movement altogether, we experience that massiveness or extensity of impressions in which movements enable us to find positions, and also to measure. But it will be objected, perhaps not without impatience, that this amounts to the monstrous absurdity of making the contents of consciousness extended. The edge of this objection will best be turned by rendering the concept of extensity more precise. Thus, suppose a postage stamp pasted on the back of the hand; we have in consequence a certain sensation. If another be added beside it, the new experience would not be adequately described by merely saying we have a greater quantity of sensation, for intensity involves quantity, and increased intensity is not what is meant. For a sensation of a certain intensity, say a sensation of red, cannot be brought to the fore of our consciousness by mere addition, without leaving the intensity unchanged; but with extensity this change is possible. For one of the postage stamps a piece of wet cloth of the same size might be substituted and the massiveness of the compound sensation remain very much the same. Intensity belongs to what may be called graded quantity; it admits of increment or decrement, but is not a sum of parts. Extensity, on the other hand, does imply plurality: we might call it latent or merged plurality or a "ground" of plurality, inasmuch as to say that a single presentation has massiveness is to say that a portion of the presentation-continuum at the moment undifferentiated is capable of differentiation.

Attributing this property of extensity to the presentation-continuum as a whole, we may call the relation of any particular sensation to this larger whole its local sign, and can see that, so long as the extensity of a presentation admits of being ignored or not to the psychophysical becoming of the fact that some two portions of the sensitive surface of the human body are anatomically alike. Not only in the distribution and character of

---

1 We are ever in danger of exaggerating the competence of a new discovery: and the associationists seem to have fallen into this mistake, not only in the use they have made of the concept of association in psychology in general, but in the stress they have laid upon the fact of movement when explaining our space-perceptions in particular. Indeed, both ideas have here conspired against them—to subject the very concept of space to the action of movement in the way that we have only to deal with a plurality of discrete impressions, and movement in keeping to the front the idea of sequence. Mill's Examination of Hamilton (3rd ed., p. 266 seq.) surely ought to convince us that, unless we are prepared to hold in Europe the "unbounded area of space that lies from one of time" (p. 276), we must admit the inadequacy of our experience of movement to explain the origin of it.

2 To illustrate what is meant by different complexes it will be enough to refer to the "mental representations" of things which fact that scarcely two portions of the sensitive surface of the human body are structurally alike. Not only in the distribution and character of
this point of view we may say that more partial presentations are concerned in the sensation corresponding to two stamps than in that corresponding to one. The fact that these partial presentations, though identical in quality and intensity, on the one hand are not wholly identical, and on the other are presented only as a quantity and not as a plurality, is explained by the distinctness along with the continuity of their local signs. Assuming that to every distinguishable part of the body there corresponds a local sign, we may allow that at any moment only a certain portion of this continuum is definitely within the field of consciousness; but no one will maintain that a part of one hand is ever felt as continuous with part of the other or with part of the face. Local signs have thus an invariable relation to each other: two continuous signs are not one day coincident and the next widely separate. This last fact is only implied in the mere massiveness of a sensation in so far as this admits of differentiation into local signs. We have, then, when the differentiation is accomplished, a plurality of presentations constituting an extensive continuum, presented simultaneously, and having certain fixed and invariable relations to each other. Of such experience the typical case is that of passive touch, though the other senses exemplify it. It must be allowed that our concept of space in like manner involves a fixed continuity of positions; but then it involves, further, the possibility of movement. Now in the continuum of local signs there is nothing whatever of this; we might call this continuum an implicit plem. It only becomes the presentation of occupied space after its several local signs are complicated in an orderly way with active touches, when in fact we have experienced the contrast of movements with contact and movements without, i.e. in vacuo. It is quite true that we cannot now think of this plem except as a space, because we cannot divest ourselves of these motor experiences by which we have explored it. We can, however, form some idea of the difference between the perception of space and this one element in the perception by contrasting massive internal sensations with massive superficial ones, or the general sensation of the body as "an animated organism" with our perception of it as extended. Or we may express the difference by remarking that extension implies the distinction of here and there, while extensity rather suggests ubiquity. It must seem strange, if this conception of extensity is essential to a psychological theory of space, that it has escaped notice so long. The reason may be that in investigations into the origin of our knowledge of space it was always the concept of space and not our concrete space percepts that came up for examination. Now in space as we conceive it one position is distinguishable from another solely by its co-ordinates, i.e. by the magnitude and signs of certain lines and angles, as referred to a certain datum or basis. This element of our motor experiences seems fully to explain. But on reflection we ought, surely, to be puzzled by the question, how these coexistent positions could be known before those movements were made which constitute them different positions. The link we thus suspect to be missing is supplied by the more concrete experiences we obtain from our own body, in which two positions have a qualitative difference or "local colour" independently of movement. True, such positions would not be known as spatial without movement; but neither would the movement be known as spatial had those positions no other difference than such as

arises from movement. In a balloon drifting steadily in a fog we should have no more experience of change of position than if it hung becalmed and still.

We may now consider the part which movement plays in elaborating the presentations of this dimensionless continuum into percepts of space. In so doing we must bear in mind that while this continuum implies the incopresentability of two impressions having the same local sign, it allows not only of the presentation of sensations of varying massiveness, but also of a sensation involving the whole continuum simultaneously, as in Bain’s classic example of the warm bath. As regards the motor element itself, the first point of importance is the incopresentability and invariability of a successive series of auxilio-motor or kinaesthetic presentations, P₁, P₂, P₃, P₄, P₅, P₆, P₇ cannot be presented along with P₂ and from P₃, it is impossible to reach P₁ again save through P₂ and P₃. Such a series, taken alone, is the stuff of which sensation is regarded as something but the knowledge of an invariable sequence of impressions which it was in our own power to produce. Calling the series of P₁ “positional signs,” the contrast between them and local signs is obvious. Both are invariable, but succession characterizes the one, simultaneity the other; the one yields potential position without place, the other potential place (τόσα) without position; hence we call them both merely signs. But in the course of the movements necessary to the exploration of the body—probably our earliest lesson in spatial perception—these positional signs receive a new significance from the active and passive touches that accompany them, just as they impart to these last a significance they could never have alone.

It is only in the resulting complex that we have the presentations of actual position and of spatial magnitude. For space, though conceived as a coexistent continuum, excludes the notion of omnipresence or ubiquity; two positions, l₁ and l₂, must coexist, but they are not strictly distinct positions so long as we conceive ourselves present in the same sense in both. But, if P₁ and P₂ are, e.g. two impressions produced by compass points touching two different spots as l₁ and l₂ on the hand or arm, and we place a finger upon l₂ and move it to l₃ experiencing thereby the series P₁, P₂, P₃, P₄, this series constitutes l₁ and l₃ into positions and also invests F₁ and F₃ with a relation not of mere distinctness as τοσά but of definite distance. The resulting complex perhaps admits of symbolization as follows:

<table>
<thead>
<tr>
<th>F₁</th>
<th>F₂</th>
<th>F₃</th>
<th>F₄</th>
<th>F₅</th>
</tr>
</thead>
<tbody>
<tr>
<td>P₁</td>
<td>P₂</td>
<td>P₃</td>
<td>P₄</td>
<td>P₅</td>
</tr>
</tbody>
</table>

Here the first line represents a portion of the actual continuum, F₁ and F₂ being distinct "feels," if we may so say, or passive touches presented along with the fainter sensations of the continuum as a whole, which the general "body-sense" involves; T₁ and T₂, alone, would afford us, it is regarded as nothing but the corresponding kinaesthetic sensation regarded as "positional sign"; the rest of the succession, as not actually present at this stage but capable of revival from past explorations, is symbolized by the l₁ l₂ and b₁ b₂. When the series of movements is accompanied by active touches without passive there arises the distinction between one’s own body and foreign bodies; when the initial movement of a series is accompanied by both active and passive touches, the final movement by active touches only, and the intermediate movements are unaccompanied by either, we get the further presentation of empty space lying between us and them—but only when by frequent experience of contacts along with those intermediate movements we have come to know all movement as not only succession but change of position. Thus active touches come at length to be projected, passive touches alone being localized in the stricter sense. But in actual fact, of course, the localization of one impression is not perfected before that of another is begun, and we must take care lest our necessarily meagre exposition give rise to the mistaken notion
that localizing an impression consists wholly and solely in performing or imaging the particular movements necessary to add active touches to a group of passive impressions. That this cannot suffice is evident merely from the consideration that a single position out of relation to all other positions is a contradiction. Localisation, though it depends on many special experiences of the kind described, is not like an artificial product which is completed a part at a time, but is essentially a growth, its several constituents advancing together in definiteness and interconnexion. So far has this development advanced that we do not even imagine the special movements which the localization of an impression implies, that is to say, they are no longer distinctly represented as they would be if we definitely intended to make them: the past experiences are "retained," but too much blended in the mere perception to be appropriately spoken of as remembered or imaged.

A more apparent, less distinctive character of our earliest spatial percepts it will be appropriate to animadvert on a misleading implication in the current use of such terms as "localization," "projection," "bodily reference," or "spatial reference" and the like. The implication is that external space, or the body as extended, is in some sort presented or supposed apart from the localization or reference of impressions to such space. That it may be possible to put a book in its place on a shelf there must be (1) the place, and 2) distinct and apart from it, the place on the shelf. But in the latter sense the presentiment impression elements, not that a second distinct object is presented and some indecisive connexion established between the impression and it, still less that the impression is referred to something not strictly present. The truth is that the body as extended is from the psychological point of view not perceived at all apart from localization impressions. In like manner impressions projected (or the absence of impressions projected) constitute all that is perceived as external space; it is not till localization impressions are superimposed that external space becomes a separate entity. Later stage, after many varying experiences of different impressions similarly localized or projected, that even the mere materials are present for the formation of such an abstract concept of space as space occupies. From this it follows that the being themselves at this later stage, are apt to permit the oversight of introducing it into the earlier stage which they have to expend.

20. In a complex percept, such as that of an orange or a piece of wax, may be distinguished the following points concerning which psychology may be expected to give an account: (a) the object's reality, (b) its solidity or occupation of space, (c) its unity and complexity, (d) its permanence, or rather its continuity in time and (e) its substantiality and the connexion of its attributes and powers. Though, in fact, these are most intimately blended, our presentation will be clearer if we consider each for a moment apart. We can, of course, appreciate the reality and unity and complexity of the wax; but here both terms, with a certain shade of difference, in so far as actual is more appropriate to movements and events, are used, in antithesis to whatever is ideal or represented, for what is sense-given or presented. This seems at least their primary psychological meaning; and it is one most in vogue in English philosophy at any rate, over-tinted as that is with psychology. Any examination of this characteristic will be best deferred till we come to deal with ideation generally (see §21 below). The wax, or indeed anything else, is a single idea, and actuality is not a single distinct element added to the others which enter into the complex presentation we call a thing.

1. Cf. on this point Poincaré, _La Science et l'Hypothèse_, pp. 74 sqq.

2. Thus Locke says, "Our simple ideas [i.e. presentations or impressions, as we should now say] are all real...and not fictions at pleasure. The real, for the mind, is the only possible object of the idea, more than it has received" (_Essay_, ii. 30). And Berkeley says, "The ideas impressed on the senses by the Author of Nature are called real things; and those excited in the imagination, being less the product of this almost, are more properly termed ideas or images of things, which they copy or represent" (_Prin. of Hum. Know.,_ pt. i. § 33).
not instantly group together all the sounds and all the colours, all the touches and all the smells; but, dividing what is given together, single out a certain sound or smell as belonging together with a certain colour and feel, similarly singled out from the rest, to what we call one thing. We might wonder, too—those at least who have made so much of association by similarity ought to wonder—that, say, the white of snow calls up directly, not other shades of white or other colours, but the expectation of cold or of powdery softness. The first step in this process has been the simultaneous projection into the same occupied space of the several impressions which we thus come to regard as the qualities of the body filling it. Yet such simultaneous and coincident projection would avail but little unless the constituent impressions were again and again repeated in like order so as to prompt anew the same grouping, and unless, further, this constancy in the one group was present along with changes in other groups and in the general field. There is nothing in its first experience to tell the infant that the song of the bird does not inhere in the hawk when the notes proceed, but that the fragrance of the mayflower does. It is only where a group, as a whole, has been found to change its position relatively to other groups, and—a part from casual relations to other bodies it chance to present during the thing complex can become distinct units and mark a world of things. Again, because things are so often a world within themselves, their several parts or members not only having distinguishing qualities but moving and changing with more or less independence of the rest, it comes about that what is from one point of view one thing becomes from another point of view several—like a tree with its separable branches and fruits, for example. Wherein then, more precisely, does the unity of a thing consist? This question, so far as it here admits of answer, carries us over to temporal continuity.

Temporal Continuity.

d. Amidst all the change above described there is one thing comparatively fixed: our own body is both constant as a group and a constant item in every field of groups; and not only so, but it is beyond all other things an object of continual and peculiar interest, inasmuch as our earliest pleasures and pains depend solely upon it and what affects it. The body becomes, in fact, the earliest form of self, the first datum for our later conceptions of permanence and individuality. A continuity like that of self is then transferred to other bodies, what happens during the thing complex can become distinct units and mark a world of things. Again, because things are so often a world within themselves, their several parts or members not only having distinguishing qualities but moving and changing with more or less independence of the rest, it comes about that what is from one point of view one thing becomes from another point of view several—like a tree with its separable branches and fruits, for example. Wherein then, more precisely, does the unity of a thing consist? This question, so far as it here admits of answer, carries us over to temporal continuity.

21. Before the intuition of things has reached a stage so complete and definite as that just described, imagination or ideation as distinct from perception has well begun. In passing to the consideration of this higher form of mental life we must endeavour first of all analytically to distinguish the two as precisely as may be and then to trace their gradual development.

To begin, it is very questionable whether Hume was right in applying Locke's distinction of simple and complex to ideas in the narrower sense as well as to impressions. "That idea of red," says Hume, "which we form in the dark and that impression which strikes our eyes in the sunshine differ only in degree, not in nature." But what he seems to have overlooked is that, whereas we may have a mere sensation red, we can only have an image or representation of a red thing or a red form, i.e. red in some way ideally projected or intuited. In other words, there are no ideas—though there are concepts—answering to simple or isolated impressions. The synthesis which has taken place in the evolution of the percept can only partially fail in the idea, and never so far as to leave us with a chaotic "manifold" of mere sensational remnants. On the contrary, we find that in "constructive imagination" a new kind of effort is often requisite in order partially to dissociate these representational complexes as a preliminary to new combinations. But it is doubtful whether the results of such an analysis are ever the ultimate elements of the percept, that is, merely isolated so far as to "exist" in a faint form. We may now try to ascertain further the characteristic marks which distinguish what is imagined from what is perceived.

1 The distinction between the thing and its properties is one that might be more fully treated under the head of "Thought and Conception." Still, inasmuch as the material warrant for these concepts is contained more or less implicitly in our perceptions, some consideration of it is in place here.

2 "Idea ... a word of my own coinage," says James Mill.

3 Treatise of Human Nature, bk. i. pt. i. § 1.
The most obvious difference is that which Hume called "the force or liveliness" of primary presentations as compared with secondary presentations. But what exactly are we to understand by this somewhat figurative language? A simple difference of intensity cannot be all that is meant, for—the though we may be momentarily confused—we can perfectly well distinguish the faintest impression from an image; moreover, we can reproduce such faintest impressions in idea. The whole subject of the intensity of representations awaits investigation. Between moonlight and sunlight or between midday and dawn we can discriminate many grades of intensity; but it does not appear that there is any corresponding variation of intensity between them when they are not seen but imagined. Many persons suppose they can imagine a waxing or a waning sound or the gradual abatement of an intense pain; but what really happens in such cases is probably not a rise and fall in the intensity of a single representation, but a change in the complex represented. In the primary presentation there has been a change of quality along with change of intensity, and not only so, but most frequently a change in the muscular adaptations of the sense-organs too, to say nothing of organic sensations accompanying these changes. A representation of some or all of these attendants is perhaps what takes place when variations of intensity are supposed to be reproduced. Again, hallucinations are often described as abnormally intense images which simply, by reason of their intensity, are mistaken for perceptions. But such statement, though supported by very high authority, is almost certainly false, and would probably never have been made if physiological and epistemological considerations had been excluded as they ought to have been. Hallucinations, when carefully examined, seem just as much as perceptions to contain among their constituents some primary presentation—either a so-called subjective sensation of sight and hearing or some organic sensation due to deranged circulation or secretion. Intensity alone, then, will not suffice to discriminate between impressions and images.

What we may call superior steadiness is perhaps a more constant and not less striking characteristic of perceptions. Ideas are not only in a continual flux, but even when we attempt forcibly to detain one it varies continually in clearness and completeness, reminding one of nothing so much as of the illuminated devices made of gas jets, common at fêtes, when the wind sweeps across them, momentarily obliterating one part and at the same time intensifying another. There is not this perpetual flow and flicker in what we perceive. The impressions entering consciousness at any one moment are psychologically independent of each other; they are equally independent of the presence of their objects. But in the primary presentation—either a so-called subjective sensation of sight and hearing or some organic sensation due to deranged circulation or secretion. Intensity alone, then, will not suffice to discriminate between impressions and images.

We may call superior steadiness is perhaps a more constant and not less striking characteristic of perceptions. Ideas are not only in a continual flux, but even when we attempt forcibly to detain one it varies continually in clearness and completeness, reminding one of nothing so much as of the illuminated devices made of gas jets, common at fêtes, when the wind sweeps across them, momentarily obliterating one part and at the same time intensifying another. There is not this perpetual flow and flicker in what we perceive. The impressions entering consciousness at any one moment are psychologically independent of each other; they are equally independent of the presence of their objects. But in the primary presentation—either a so-called subjective sensation of sight and hearing or some organic sensation due to deranged circulation or secretion. Intensity alone, then, will not suffice to discriminate between impressions and images.

But how is this contrariety between impression and image possible? With eyes wide open, and while clearly aware of the actual field of sight and its filling, one can recall or imagine a wholly different scene: lying warm in bed one can imagine oneself out walking in the cold. It is useless to say the times are different, that what is perceived is present and what is imaged is past or future. The images, it is true, have certain temporal marks—of which more presently—by which they may be referred to what is past or future; but as imaged they are present and, as we have just observed, are regarded as actual whenever there are no correcting impressions. We cannot at once see the sky red and blue; how is it we can imagine the one while perceiving it to be the other? When we attempt to make the field of sight at once red and blue, as in looking through red glass with one eye and through blue glass with the other, either the colours merge and we see a purple sky or we see the sky first of the one colour and then of the other in irregular alternation. This does not happen between impression and image shows that, whatever their connexion, images as a whole are distinct from the presentation-continuum and cannot with strict propriety be spoken of as revived or reproduced impressions. This difference is manifest in another respect, viz., when we compare the effects of diffusion in the two cases. An increase in the intensity of the sensation of touch entails an increase in the extensity; an increase of muscular innervation entails irradiation to adjacent muscles; but when a particular idea becomes clearer and more distinct, there rises into consciousness an associated idea qualitatively related probably to impressions of quite another class, as when the smell of tar calls up memories of the sea-beach and fishing-boats. Since images are thus distinct from impressions, and yet so far continuous with each other as to form a train in itself unbroken, we should be justified, if it were convenient, in speaking of images as changes in a new continuum; and later on we may see that this is convenient.

Impressions then—unlike ideas—have no associates to whose presence their own is accommodated and on whose intensity their own depends. Each bids independently for attention, so that often a state of distraction ensues, such as the train of ideas left to itself never occasions. The better to hear we listen; the better to see we look; to smell better we dilate the nostrils and sniff; and so with all the special senses: each sensory impression sets up nascent movements for its better reception. In like manner there is also a characteristic adjustment for images which can be distinguished from sensory adjustments almost as readily as these are distinguished from each other. We become most aware of this as, mutatis mutandis, we do of them, when we voluntarily concentrate attention upon particular ideas instead of remaining mere passive spectators, as it were, of the general procession. To this idealational adjustment may be referred most of the strain and "head-splitting" connected with recollecting, reflecting and all that people call headwork; and the "absent look" of one intently thinking or absorbed in reverie was partly due to the absence of sensory adjustment that accompanies the concentration of attention upon ideas.

22. But, distinct as they are, impressions and images are still closely connected. In the first place, there are two or three well-marked intermediate stages, so that, though we cannot directly observe it, we seem justified in assum- ing a steady transition from the one to the other. As the first of such intermediate stages, it is usual to reckon what are often, and—so far as psychology goes—inaccurately styled after-images. They would be better described as after-sensations, inasmuch as they are due either (1) to the persistence of the original peripheral excitation after the stimulus is withdrawn, or (2) to the effects of the exhaustion or the repair that immediately follows this excitation. In the former case they are qualitatively identical with the original sensation and are called "positive," in the latter they are supposed to be "negative" (see Vision). These last, then, of which we have clear instances only in connexion with sight, are obviously in no way connected with the discrimination of past and future psychologically presupposes the contrast of impression and image. Moreover, as we shall see, the distinction between present and past or future psychologically presupposes the contrast of impression and image.

Organic sensations, though distinguishable from images by their definite though often anatomically inaccurate localization, furnish no parallel. In any case having nothing like the after-image. But in another respect they are still more clearly marked off from images, viz., by the pleasure or pain they directly occasion.
sort re-presentations of the original impression, but a sequent presentation of diametrically opposite quality; while positive after-sensations are, psychically regarded, nothing but the persistence of sensations in a state of ennervation. It is this continuance and gradual waning after the physical stimulus has completely ceased that give after-sensations their chief title to a place in the transition from impression to image. There is, however, another point: after-sensations are less affected by movement than impressions are. If we turn away our eyes we cease to see the flame at which we have been looking, but the after-image remains still projected before us and continues localized in the dark field of sight, even if we close our eyes altogether. This fact that movements do not suppress them, and the fact that yet we are distinctly aware of our sense-organs being concerned in their presentation, serve to mark off after-sensations as intermediate between primary and secondary presentations. The after-sensation is in reality more elementary than either the preceding percept or its image. In both these, in the case of sight, objects appear in space of three dimensions, i.e. with all the marks of solidity and perspective; but the so-called after-image lacks all these.

Still further removed from normal sensations (i.e. sensations determined by the stimulus appropriate to the sense-organ) are the after-sensations which are unnoticed but probably experienced more or less frequently by everybody—cases, that is, in which sights or sounds, usually such as at the time were engrossing and impressive, suddenly reappear several hours or even days after the physical stimuli, as well as their effects on the terminal sense-organ, seem entirely to have ceased. Thus workers with the microscope often see objects which they have examined during the day stand out clearly before them in the dark; it was indeed precisely such an experience that led the anatomist Henle first to call attention to these facts. But he and others have wrongly referred them to what he called a "sense-memory"; all that we know is against the supposition that the eye or the ear has any power to retain and reproduce percepts. 2 Recurrent sensations  have all the marks of percepts which after-sensations lack; they only differ from what are more strictly called "hallucinations" in being independent of all subjective suggestion determined by emotion or mental derangement.

In what Fechner has called the "memory after-image" or the primary memory-image, as it is better termed, we have the image presented in its earliest form. As an instance of what is meant may be cited the familiar experience that a knock at the door, the hour struck on the clock, the face of a friend whom we have passed unnoticed, may sometimes be recognized a few minutes later by means of the persisting image, although—apparently—the actual impression was entirely disregarded. But in vision the primary memory-image can always be obtained, and is obtained to most advantage, by looking intently at some object for an instant and then closing the eyes or turning them away. The image of the object will appear for a moment very vividly and distinctly, and can be so recovered several times in succession by an effort of attention. Such reinstatement is materially helped by rapidly opening and closing the eyes, or by suddenly moving them in any way. In this respect a primary memory-image resembles an after-sensation, which can be repeatedly revived in this manner when it would otherwise have disappeared. This seems to show that the primary memory-image in such cases owes its vivacity in part to a positive after-sensation; at any rate it proves that it is in some way still sense-sustained. But in other respects the two are very different: the after-sensation is necessarily presented if the intensity of the original sensation surpasses a certain threshold, and cannot be presented otherwise, however much we attend. Moreover, the after-sensation is only for a moment positive, and then passes into the negative or complementary phase, when, so far from even contributing towards the continuance of the original percept, it directly hinders it. Primary memory-images on the other hand, and indeed all images, depend mainly upon the attention given to the impression; provided that was sufficient, the faintest impression may be long retained, and without it very intense ones will soon leave no trace. The primary memory-image retains so much of its original definiteness and intensity as to make it possible with great accuracy to compare two physical phenomena, one of which is in this way "remembered" while the other is really present. For the most part this is indeed a more accurate procedure than that of dealing with both together, but it is only possible for a very short time. From Weber's experiments with weights and lines 2 it would appear that even after 10 seconds a considerable waning has taken place, and after 100 seconds all that is distinguishable of the memory-image is lost.

On the whole, then, it appears that the ordinary memory-image is a joint effect; it is not the mere residuum of changes in the presentation-continuum, but an effect of these only when there has been some concentration of attention upon them. It has the form of a percept, but is not constituted of revived impressions, for the essential marks of impressions are absent; there is no localization in, or projection into, external space, neither is there the motor adaptation, nor the tone of feeling, incident to the reception of impressions. Ideas do not reproduce the intensity of these original constituents, but only their quality and complication. What we call the vividness of an idea is of the nature of intensity, but it is an intensity very partially and indirectly determined by that of the original impression; it depends much more upon the state of what we shall call the memory-continuum and the attention the idea receives. The range of vividness in ideas is probably comparatively small; what are called variations in vividness are often really variations in distinctness and completeness. Where we have great intensity, as in hallucinations, primary presentations may be forcibly repeated by a very small exposure.

It is manifest that the memory-continuum has been in some way formed out of or differentiated from the presentation-continuum by the movements of attention, but the precise connexion of the two continua is still very difficult to determine. We see perhaps the first distinct step of this evolution in the primary memory-image: here there has been no cessation in presentation, and yet the characteristic marks of the impression are gone, so much so, indeed, that superposition without "fusion" with an exactly similar impression is possible. We have now to inquire into the genesis and development of ideation.

**Genesis and Development of Ideation.**

23. We find ourselves sometimes engrossed in present percepts, as when tracing, for example, the meanderings of an ant; at other times we may be equally absorbed in reminiscences; or, again, in pure reverie and "castle-building." Here are three well-marked forms of conscious life: the first being concerned with what is, the second with what has been, and the third with the merely possible. Again, the first involves definite spatial and temporal order, though the temporal order, as just said, is in the main restricted to the "sensible present"; the second involves only definite time-order; and the last neither in a definite way. Thus, analytically regarded, perception, memory, imagination, show a steady advance. In infancy the first

1 The following scant quotation from Fechner, one of the best observers in this department, must suffice in illustration. "Lying awake in the early morning with my eyes partly closed, though open, I sometimes see with my eyes open—when I wish to close them for a moment, the black after-image of the white bed immediately before me and the white after-image of the black stove-pipe some distance away against the opposite wall. . . . Both [after-images] appear as if they were in juxtaposition in the same plane; and, though—when my eyes are open—I seem to see the white bed in its entire length, the after-image—when my eyes are shut—presents instead only a narrow black stripe owing to the fact that the bed is seen considerably foreshortened. But the memory-image on the other hand completely reproduces the pictorial illusion as it "appears when the eyes are open."" (Elemente der Psychophysik, ii, 473).

2 Die Lehre vom Tastsinne, &c., pp. 86 seq.

3 As we have seen that there is a steady transition from percep to image, so, if space allowed, the study of memory might make clear an opposite and abnormal process—the passage, that is to say, of images into percepts, for such, to all intents and purposes, are hallucinations of perception, psychologically regarded.
predominates, while senility lapses back to the second; in the third, where similarities suggest themselves and the contrast of actual and possible is explicit, we have at length the groundwork of logical comparison. Nevertheless, since imagination plays a conspicuous part in child life before much personal reminiscence appears, it would seem probable that ideas do not first arise as definite memory-images or reminiscences. On the other hand, in the so-called homing instincts of the lower animals we have evidence of isolated "memories" of a simpler form than ours.

The subject is as difficult as it is interesting and important, and we can only hope that a final solution of the question, by clearing away obstacles, will elucidate the unexplained connotation of such leading terms as memory, association and idea. Even what is most fundamental of all, that "plasticity" which we have termed retentiveness, differentiation and integration, is sometimes described as if it already involved memory-images and their association. Ideas, that is to say, are identified with mere "residua" of former impressions, and yet at the same time are spoken of as "copies of these": which is much like saying that the evening twilight is a "replica" of the noonday glare as well as parting gleam. Again, the continuous differentiation and redintegration of the representational continuum which mark the progress of perceptual experience are resolved into an original multiplicity of presentations which are associated by "adhesion" of the contiguous, yet before the differentiation there was no plurality, and after the integration there is only a complex unity, comparable perhaps with another unity, the unity with cement, put together with cement. This mistaken identification by the Associationists of later processes with simpler and earlier ones, by which they are only partially explained, has not only obscured the matter, but prevented a comparison of the progress of thought on which we are entering—that concerning the genesis and development of ideas—from being ever effectually raised. The discussion of this question will incidentally yield the best refutation of those views.

Experience, we say, is the acquisition of practical acquaintance and efficiency as the result of repeated opportunity and effort. This means that strangeness on the cognitive side gives place to familiarity, and that on the active side clumsiness is superseded by skill. But though analytically distinct, the two sides are, as we have already insisted, actually inseparable: to the uninteresting we are indifferent, and what does not call for active response is ignored. If the original presentations whether sensory or motor, be A, B, C, we find then that they gradually acquire a new character, become, let us say, A′, B′, C′, representing the eventual familiarity or facility, as the case may be. We find, again, a certain sameness in this character, however various the presentations may be, and again a sameness which points to the presence of subjective constitutions, and to these we may assign the "feelings" that enter into accommodation and adjustment.

This factor is important as evidence of a subjective co-operation which may enable us to dispense with the mutual "adhesions" and "attractions" among presentations, on which the Associationists rely. But it is obvious that there must be an objective factor as well; and it is this objective factor in the process giving rise to γ that now primarily concerns us. We have described that process as assimilation or immediate recognition: the older psychology described it as association of the completely similar, or as automatic association. That the two views have something in common is shown by the juxtaposition of "automatic" and "immediate," "similarity" and "assimilation." To prepare the way for our discussion, let us first accept in these points of agreement. "When I look at the full moon," said Bain, "I am instantly impressed with the state arising from all my former impressions of her disc added together." This we may symbolize in the usual fashion as A + a1 + a2 + a3 + · · · ; now, it will be granted (i) that the present occurrence (full moon) has been preceded by a series of like occurrences, enumerable as 1, 2, 3, · · · ; (2) that the present experience (A) is what it is in consequence of the preceding experiences of these occurrences; and (3) that it "arises instantly" as the joint result of such preceding experiences. But it is denied (i) that this present experience is the mere sum, or even the mere "fusion," of the experiences preceding it; (2) that they were qualitatively identical; (3) that they persist severally unaltered, in such wise that experience "drags at each remove a lengthening chain" of them. In the case of dexterities, where γ answers to facility, it is obvious that there is no such series of identicals (a1, a2, · · · aγ) at all. From the first rude beginning—say the schoolboy's pot-hooks—up to the finished performance of the adept there is continuous approximation: awkward and bungling attempts, passing gradually into the bold strokes of mastery. Nor is the case essentially different in cognition where γ answers to familiarity; if we attend, as it is plainly we ought, not to the physical fact cognized, but to the individual's perception of it. This, too, is an acquisition, has entailed activity, and is marked by gradual approximation towards clearness and distinctness. The successive experiences of n identical occurrences do not then result in an accumulation of n identical residua. The ineptness of the atomistic psychology with its "physical" and "chemical" analysis is nowhere more apparent than here. Considering the intimate relation of life and mind, and the strong physiological bias shown by the Associationists from Hartley onwards, it is surely extraordinary how completely they have failed to appreciate the light-bearing significance of such concepts as function and development. Facility and faculty (or function) are the same, both etymologically and actually. As the perfected structure is not so many rudimentary structures "added together," but something that supersedes them completely, must we not say the same of the perfected function? The less fit is not embodied in the fittest that finally survives. Development implies change of form in a continuous whole: every growth into means an equal growth out of: thus one cannot find the caterpillar in the butterfly. Between organic development and mental development there is then more than an analogy.

But through assimilation cannot be analysed into a series of identical ideas (a1, a2, · · · aγ), either "added together" or "instantaneously fused," yet it does result in an a which may provisionally be called an idea. Such idea is, however, neither a memory-idea in the proper sense nor an idea within the meaning of the term implied in imagination or ideation. For it is devoid of the temporal sign\(^1\) indicated by the subscript numerals in \(a_1, a_2, \ldots\), and it does not yet admit of reproduction as part of an ideational continuum, one, that is, divested of the characteristics belonging to the actual and sensibly present. It is, so to say, embryonic, something additional to the mere sensation assimilated, and yet something less than a "free or independent idea." It is, as it has been happily called,\(^2\) a tied (gebundene) or implicit idea. We have clear evidence of the sense-bound stage of this immature "idea" in the so-called "memory afterimage" (cf. § 22). There is, however, nothing in this memory, such as to serve as the γ of an idea afterwards and, after it has perished, that would therefore be a less objectionable name for it. This after-percept is entirely sense-sustained and admits of no ideal recall, though—in minds sufficiently advanced—it may persist for a few moments, and so form the basis of such comparison with a second sensation, as we find in the experiments of Weber, Fechner and others.\(^3\) At a still lower level, or in actual perception, we cannot assume even this amount of partial independence, though continuity clearly points to something beyond the bare sensation, which is a pure abstraction, as we may presently see.

It is saying too little to maintain, as some do, that this "something" is subconscious, on the ground that it is not discoverable by direct analysis. Yet it is saying too much, regardless of this defect, to describe a percept as a representational-representative

---

1. On this term cf. below, §§ 24, 28.
3. Recent experiments, however, seem to prove that the after-percept is not the sole factor, and often is not a factor at all in such successive comparison (so-called); but that what is now termed "the absolute impression" may supplement it or even replace it altogether. As to what is meant by absolute impression, cf. § 14, c.
complex, if representation is to imply the presence of a free or independent idea. To call this "something" a tied or naseent idea on the ground of its possible later development into an independent representation seems, then, nearest the truth. The same meaning is sometimes given a word by a way of saying that all cognition (perception) is recognition. This statement has been met by elaborate expositions of the difference between knowing and knowing again, the irrelevance of which any lexicon would show; and, further, by the demand: How on such a view is a first cognition possible, or how is an indefinite regress of assimilation to be avoided? We may confidently reply that it cannot be avoided: an absolute beginning of experience, whether phylogenetically or ontogenetically, is beyond understanding. The mere further assimilation, in this sense all cognition is further cognition, and a bare sensation is, as said, an abstraction representing a limit to which we can never regress.

We find evidence, again, of ideas in the making in what Lewes called preperception. Of this instance in plenty are furnished by everyday illusions, as when a scarecrow is hailed by the traveler who mistakes it for a husbandman, or when what is taken for an orange proves to be but an imitation in wax. In reality all complex percepts involve preperception; and, so far, it must be allowed that such percepts are directly analysable into representational-representative complexes. Nevertheless, the representational element is not yet, and may never become, an idea proper. The sight of ice yields a foretaste of its coldness, the smell of baked meats a foretaste of their savour. Such percepts differ from free ideas just as after percepts do: they are still and absolute; but not so absolute. Nor can we say that such perception be with any propriety identified either with the association pertaining to memory or with that specially pertaining to ideation; though, no doubt, the two processes—complication and association—are genetically continuous, as are their respective constituents, nascent and free ideas. The whole course of perceptual integration being determined and sustained by subjective interest, involves from the outset, as we have seen, concurrent nocative impulses; and thus the same assimilation that results in familiarity and preperception on the subjective side results in facility and purpose on the conative side.

Knowing immediately what to do is here the best evidence of knowing what there is to do with; the moth that flies into the candle has assuredly no preperception of it, and does not act with purpose. Bearing this in mind, we may now see one way, and probably the earliest, in which tied ideas become free.

The contrast between the actual and the possible constitutes, as we have seen, the main difference between experience at the perceptual and experience at the ideational stage. A subject conscious of the contrast may be called a preperceptionist. Such knowledge is attained, not through any quasi-mechanical inter-action of presentations, but usually through bitter experience. The chapter of accidents is the Bible of fools, it has been said; but we are all novices at first, and get wisdom chiefly by the method of trial and failure. Things are not always different in what to us are their essential properties, but they so differ from time to time. Resembances are frequent enough to give us familiarity and confidence; yet uniformity is flecked by diversity, and thwarted intentions disclose possibilities for which we were not prepared. What was taken for sugar turns out to be salt; what was seized as booty proves to be bait. We catch many Tatars, and so learn wariness in a rough school. In such wise preperceptions displaced by the actual fact yield the "what" or "what" it used to be, the "what" that is freed from the exclusive hold of the real. In a new situation after such adventures the attitude assumed—if, for brevity, we describe it in terms of our own still more advanced experience—is of this sort: It may be a wasp, if so, 1 back; it may be a rabbit, if so, 1 spring." Instead of unquestioned preperception that "makes mind on the mouth water," we have the alternative possibilities present as "free ideas," and action is in suspense, the alternative courses, that is to say, again present only in ideas. It is easy to see how in such situations a free idea, a "what" sundered from its "that," will tend to loosen the sensory ties of alternative, still implicit ideas. On the cognitive side, from immediate assimilation an advance is made towards mediate cognition, towards comparison; on the active side there is advance from impulsive action towards deliberate action.

We conclude, then, that implicit ideas—the products of assimilation, and integrated as such in complex percepts and the motor co-ordinations to which they lead—are more likely to emerge as free ideas the more this perceptual complexity increases. Perception in the lower animals, which give no signs of either memory or ideation, has apparently no such complexity. A fish, for example, can feel, smell, taste, see, and even hear, but we cannot assume solely on that account that it has any percepts to which its five senses contribute, as they do to our percept, say, of an orange or a peppermint. Taking voluntary movements as the index of psychic life, it would seem that the fish's movements are instigated and guided by its senses, not collectively but separately. Thus a fish-fish, according to Steiner, seeks its food, endangers itself by its kicks, and so on. The sense of smell is severed, or the fore-brain, in which when they end, is destroyed, it ceases to feed spontaneously. The carp, on the other hand, appears to search for its food wholly under the guidance of sight, and continues to do so just as well as when the fore-brain is removed, the mid-brain, whence the optic nerves spring, seeming to be the chief seat of what intelligence it has. Against, Bateson observes: "There can be no doubt that solos also perceive objects approaching them, for they bury themselves if a stroke at them is made with a landing-net; yet they have no recognition of a worm hanging by a thread immediately over their heads, and will not take it even if it touch them, but continue to feel it aimlessly on the bottom of the tank, being aware of its presence by the sense of smell." To this inability to combine simple percepts into one complex percept of a single object or situation we may reasonably attribute the fish's lack of true ideas, and consequent lack of sagacity. The sagacity even of the higher animals does not amount to "general intelligence," such as we have a "childish" to "put two and two together," as we say, whatever two "two and two" may stand for. The latter life consists of a series of definite situations and definite acts, so far the things done or dealt with altogether, the contents of the several foci or concentrations of attention, form so many integrated and comparatively isolated wholes. Round the more complicated of these, and closely connected with them, free ideas arise as sporadic groups, making possible those "lucid intervals," those fitful gleams of intelligence in the very heat of action, which occasionally interrupt the prevailing irrationality of the brutes. And as we cannot credit even the higher animals with general trains of ideas, just as little can we credit them with a continuous memory: indeed, it is questionable how far memory of the past, as past, belongs to them at all. For they live entirely in an up-stream, expectant attitude, and it is in this aspect that "free ideas" arise when they arise at all. We cannot imagine a dog regretting, like one of Punch's heroes, that he "did not have another slice of that mutton." The free idea (a) then at its first emergence has neither an assignable position in a continuous memory-record, as a or a, nor has it a "childish" to "put two and two together," as we say, whatever two "two and two" may stand for. The latter development brings us to the general consideration of mental association. Some light is perhaps here thrown on the reciprocal relation of "association by contrast" and "association by similarity" as severally the differentiation of partial similar and the integration of partial dissimilar.

Hence the earlier process has been named "impressational association" by Stout, Analytic Psychology, 1866, ii. pp. 27-59, and again "animal association" (Thorndike, Animal Intelligence, on Experimental Study of the Associative Processes in Animals, 1898, pp. 71, 87, and passim). But it seems preferable to confine the term "association" to the later process, in which alone the component presentations have that amount of distinctness and individuality which the term properly connotes.
Mental Association and the Memory-Continuum.

24. Great confusion has been occasioned, as we have seen incidentally, by the lax use of the term "association," and this confusion has been increased by a further laxity in the use of the term "association by similarity." In some, as the similarity amounts to identity, as in association by habit, there is a change which is more fundamental than association by contiguity, but then it is not a process of association. And when the reviving presentation is only partially similar to the presentation revived, the nature of the association does not appear to differ from that operative when one "contiguous" presentation revives another.

In the one case we have, say, a b x recalling a y, and in the other a b c recalling d e f. Now anybody who will reflect must surely see that the similarity between a b x and a y, as distinct from the identity of their partial constituent a b, cannot be the means of recall; for this similarity is nothing but the state of mind—to be studied presently—which results when a b x and a y, having been recalled are in consciousness together and then compared. But if a b, having concurred with y before and being now present in a b x, again revive y, the association, so far as that goes, is manifestly one of contiguity, albeit as soon as the revival is complete, the state of mind immediately incident may be what Bain loved to style "the flash of similarity." So far as the mere revival itself goes, there is no more similarity in this case than when there is a b c revives d e f. For the very a b c that now operates as the reviving presentation was obviously never in contiguity with the d e f that is revived; if all traces of previous experiences of a b c were obliterated there would be no revival. In other words, the a b c now present must be "automatically associated," or, as we prefer to say, must be assimilated to those residual a b c which were "contiguous" with d e f, before the representation of this can occur. And this, and nothing more than this, we have seen, is all the "similarity" that could be at work when a b x "brought up" a y.

On the whole, then, we may assume that the only principle of association we have to examine is the so-called association by contiguity, which, as ordinarily formulated, runs: Contiguity inexlicable. Any presentations whatever, which are in consciousness together or in close succession, cohere in such a way that when one recurs it tends to revive the rest, such tendency increasing with the frequency of the conjunction. It has been often contended that any investigation into the nature of association must be fruitless. But, if association is thus a first principle, it ought at least to admit of a statement as shall remove the necessity for inquiry. So long, however, as we are asked to conceive presentations originally distinct and isolated becoming eventually linked together, we shall naturally feel the need of some explanation of the process, for not only the isolation nor the links are clear—not the isolation, for we can only conceive two presentations separated by other presentations intervening; nor the links, unless these are also presentations, and then the difficulty recurs. But, if for contiguity we substitute continuity and regard the associated presentations as parts of a new continuum, the only important inquiry is how this new whole was first of all integrated.

To ascertain this point we must examine each of the two leading divisions of contiguous association—that of simultaneous presentations and that of presentations occurring in close succession. The last, being the clearer, may be taken first. In a series of associated presentations A B C D E, such as the movements made in writing, the words of a poem learned by heart, or the simple letters of the alphabet themselves, we find that each member recalls its successor but not its predecessor. Familiar as this fact is, it is not perhaps easy to explain it satisfactorily. Since C is associated both with B and D, and apparently as intimately with the one as with the other, why does it revive the later only and not the earlier? B recalls C; why does not C recall B? We have seen that any...
their integration; for the result of this occupation may be regarded as a new continuum in which A and X become adjacent parts. For it is characteristic of a continuum that changes in the intensity of any part leads to the intenser presentation of adjacent parts; and in this sense A and X, which were not originally continuous, have come to be so. We have here, then, some justification for the term secondary- or memory-continuum when applied to this continuous series of representations to distinguish it from the primary or presentation-continuum from which its constituents are derived. The most important peculiarity of this continuum, therefore, is that it is a series of representations integrated by means of the movements of attention out of the differentiations of the primary or presentation-continuum, or rather out of so much of these differentiations as pertain to what we know as the primary memory-image. These movements of attention, if the phrase may be allowed, come in the end to depend mainly upon interest, but at first appear to be determined entirely by mere intensity. To them it is proposed to look for that continuity which images lose in so far as they part with the local signs they had as percepts and cease to be either localized or projected. Inasmuch as it is assumed that these movements form the connexion between one exception and another in the memory that, they may be called "temporal signs." 2 The evidence for their existence can be more conveniently adduced presently; it must suffice to remark here that it consists almost wholly of facts connected with voluntary attention and the voluntary control of the flow of ideas, so that temporal signs, unlike local signs, are fundamentally motor and not sensory. And, unlike impressions, these can have each but a single sign, 3 the continuum of which, in contrast to that of local signs, is not rounded and complete, but continuously advancing. But in saying this we are assuming for a moment that the memory-continuum forms a perfectly single and unbroken train. If it ever actually were such, then, in the absence of any repetition of old impressions and apart from voluntary interference with the train, consciousness, till it ceased entirely, would consist of a fixed and mechanical round of images. Some approximation to such a state is often found in uncultured persons who lead uneventful lives, and still more in idiots, who can scarcely think at all.

25. In actual fact, however, the memory-train is liable to change in two respects, which considerably modify its structure, viz. (1) through the evanescence of some parts, and (2) through the reproduction of others. The more permanent and resistant a representation is in the memory-continuum as due solely to the concurrence of presentations, is perhaps the chief defect of the associationist psychology, both English and German. Spencer's endeavour to show "that physical life is distinguished from physical life by consisting of successive changes only, instead of successive and simultaneous changes" (Principles of Psychology, p. 406) is really nothing but so much testimony to the work of attention in forming the memory-continuum. It is a universal law that when, as there is good reason to do, we reject his assumption that this growing seriality is physically determined.

1 This connexion of association with continuous movements of attention makes it easier to understand the difficulty above referred to, viz. that in a series A B C D ... B revives C but not A, and so on—a difficulty that the analogy of adhesiveness or links leaves unaccountable. To ignore the part played by attention in association, to represent the memory-continuum as due solely to the concurrence of presentations, is perhaps the chief defect of the associationist psychology, both English and German. Spencer's endeavour to show "that physical life is distinguished from physical life by consisting of successive changes only, instead of successive and simultaneous changes" (Principles of Psychology, p. 406) is really nothing but so much testimony to the work of attention in forming the memory-continuum. It is a universal law that when, as there is good reason to do, we reject his assumption that this growing seriality is physically determined.

2 A term borrowed from Lotze (Metaphysik, 1st ed., p. 295), but the present writer is alone responsible for the sense here given to it and the hypothesis in which it is used.

3 Apart, that is to say, of course, from the reduplications of the memory-train spoken of below.

4 Thus as the joint effect of obliviscence and reduplication we are provided with trains of ideas distinct from the memory-thread and thereby with the material, already more or less organized, for intellectual and volitional manipulation. We do not experience the flow of ideas—save very momentarily and occasionally—altogether undisturbed; even in dreams and reverie it is continually interrupted and diverted. Nevertheless it is not difficult to ascertain that, so far as it is left to itself, it takes a very select and inveterate line of action; and it is not difficult to retrace it when it is interrupted and diverted. The steadiness and steadiness of this flow are shown by the extremely small effort necessary in order to follow it. Nevertheless from its very nature it is liable, though not to positive breaches.

5 This contrast of thread and tissue is suggested, of course, by Herbert's terms Reike and Gewebe. It is justified by the fact that memory proper follows the single line of temporal continuity, while ideation furnishes the basis for manifold logical connections.
of continuity from its own working, yet to occasional blocks or impediments to the smooth succession of images at points where reduplications diverge, and either permanently or at the particular time neutralize each other.\footnote{It is a mark of the looseness of much of our psychological terminology that facts of this kind are commonly described as cases of association. Dr Bain calls them "obstructive association," which is abhorent on a par with "progress backwards". Mr Sully's "divergent association" is better. But it is plain that what we really have is an arrest or inhibition consequent on association, and nothing that is either itself association or that leads to association.}

The flow of ideas is, however, exposed to positive interruptions from two distinct sides—by the intrusion of new presentations and of voluntary interference. The only result of such interruptions which we need here consider is the conflict of presentations.\footnote{From this it ensues that, of course, the followers have gone so far as to elaborate a complete system of psychical statics and dynamics, based on the conception of presentations as forces, and on certain more or less impossibly definable properties which the forces with which they interact. Since our power of attention is limited, it continually happens that attention is drawn off by new presentations at the expense of old ones. But, even if we regard this non-voluntary redistri- bution as disadvantageable, we yet must not suppose that still further interruptions, still such conflict to secure a place in consciousness is very different from a conflict between presentations that are already there. Either may be experienced to any degree possible without the other appearing at all; thus, absorbed in watching the sun, one might be unaware of the chilliness of the air, though recognizing, at once, as soon as the cold is felt, that, so far from being incompatible, the clearness and the coldness are causally connected. This difference between conflict and interference is attributable entirely to the fact that if we allow for a moment the propriety of the expression—and that opposition or incompatibility between presentations which is only possible when they are in consciousness has been strangely confused by the Herbartians. In the former the intense conflict of presentations is present; and, accordingly, the latter, on the contrary, quality and content are mainly concerned. Only the last requires any notice here, since such opposition arises when the ideational continuous is interrupted in the ways just mentioned.} Conflicts of Presentation.

Having thus attempted to ascertain the formation of the ideational continuum out of the memory-train, the question arises: How now are we to distinguish between imagining and remembering, and again, between imagining and expecting?

It is plainly absurd to make the difference depend on the presence of belief in memory and expectation and on its absence in mere imagination; for the belief itself depends on this difference alone of constituting it. One real and obvious distinction, however, which Hume pointed out as regards memory, is the fixed order and position of the ideas of what is remembered or expected as contrasted with "the liberty" of the imagination to transpose and change its ideas. This order and position in the case of memory are, of course, normally those of the original impressions, but it seems rather naïve of Hume to tell us that memory "is tied down to these without any power of variation," while imagination has liberty to trans- pose as it pleases, as if the originals sat to memory for their portraits, while to imagination they were but studies. Such correspondence being out of the question—as Hume takes care to state as soon as it suits him—all we have, so far, is this fixity and definiteness as contrasted with the kaleidoscopic instability of ideation. In this respect what is remembered or expected resembles what is perceived: the grouping not only does not change capriciously and spontaneously, but resists any mental efforts to change it. But, provided these characteristics are there, we should be apt to believe that we are remembering, just as, mutatis mutandis, with like characteristics we might believe that we were perceiving: hallucination is possible in either case.

This fixity of order and position is, however, not sufficient to constitute a typical reminiscence where the term is exactly used. But remembering is often regarded as equivalent to knowing and recognizing, as when on revisiting some once familiar place one remarks, "How well I remember it!" What is meant is that the place is recognized, and that its recognition awakens memories. Memory includes recognition; recognition as such does not include memory. In human consciousness, as we directly observe it, there is, perhaps, no pure recognition: here the new presentation in not only assimilated to the old, but the former framing of circumstance is reinstated, and so perforce distinguished from the present. It may be there is no warrant for supposing that such reintegration of a preceding field is ever absolutely nil, still we are justified in regarding it as extremely vague and meagre, both where mental evolution is but slightly advanced and where frequent repetition in varying and irrelevant circumstances has produced a blurred and neutral zone. The last is the case with a great part of our knowledge; the writer happens to know that lost is the Latin for "off" and buso the Latin for "toad," and may be said to remember both items of knowledge, if "remember" is only to be synonymous with "retain." But if he came across lost in reading he would think of an ox and nothing more; buso would immediately call up not only "toad" but Virgil's Georgics, the only place in which he has seen the word, and which he never read but once. In the former there is so far nothing but recognition (which, however, of course rests upon retentiveness); in the latter there is also remembrance of the time and circumstances in which that piece of knowledge was acquired. Of course in so far as we are aware that we recognize we also think that remembrance is at any rate possible, but cannot be sure of what we know, we must previously recognize, excluding novelty. But the point here urged is that there is an actual reminiscence only when the recognition is accompanied by a reinstatement of portions of the memory-train continuous with the previous presentation of what is now recognized. Summarily stated, we may say that between knowing and remembering on the one hand and imaging on the other the difference primarily turns on the fixity and completeness of the grouping in the former; in the latter there is a shifting play of images more or less "generic," reminding one of "dissolving views." Hence the first two approximate in character to perception, and are rightly called recognitions. Between them, again, the difference turns primarily on the presence or absence of temporal signs. In what is remembered these are still intact enough to ensure a localization in the past of what is recognized; in what is known merely such localization is prevented, either because of the obvivience of temporal connexions or because
the reduplications of the memory-train that have consolidated the central group have entailed their suppression. There is further the difference first mentioned, which is often only a difference of degree, viz. that reminiscences have more circums-tantiality, so to say, than mere recollections have: more of the collateral constituents of the original concrete field of consciousness are reinstated. But of the two characteristics of memory proper—(a) concreteness or circumstantiality, and (b) localization in the past—the latter is the more essential. It sometimes happens that we have the one with little or nothing of the other. For example, we may have but a faint and meagre representation of a scene, yet if it falls into and retains a fixed place in the memory train we have no doubt that some such experience was once actually ours. On the other hand, as in certain so-called illusions of memory, we may suddenly find ourselves reminded by what is happening at the moment of a preceding experience exactly like it—some even feel that they know from what is thus recalled what will happen next; and yet, because we are wholly unable to assign such representation a place in the past, instead of a belief that it happened, there arises a most distressing sense of bewilderment, as if we were haunted and had lost one’s personal bearings. It has been held by some psychologists that memory proper includes the representation of one’s past self as agent or patient in the event or situation recalled. And this is true as regards all but the earliest human experience, at any rate; still, whereas it is easy to see that memory is essential to any development of self consciousness, the converse is not at all clear, and would involve us in a needless circle.

27. Intimately connected with memory is expectation. We may as the result of reasoning conclude that a certain event will happen; we may also, in like manner, conclude that a certain other event has happened. But as we should not call the latter memory, so it is desirable to distinguish such indirect anticipation as the former from that expectation which is directly due to the interaction of ideas. Any man knows that he will die, and may make a variety of arrangements in anticipation of death, but he cannot with propriety be said to be expecting it unless he has actually present to his mind a series of ideas ending in that of death, such series being due to previous associations, and unless, further, this series owes its representation at this moment to the actual recurrence of some experience to which that series succeeded before. And as familiarity with an object or event in very various settings may be a bar to recollection, so it may be to expectation: the average Englishman, e.g. is continually surprised without his umbrella, though only too familiar with rain, since in our climate one not specially attentive to the weather obtains no clear representation of its successive phases. But after a series of events A B C D E . . . has been once experienced we instinctively expect the recurrence of B C . . . on the recurrence of A, i.e. provided the memory-train continues so far intact. Such expectation, at first perhaps slight—a mere tendency easily overborne—becomes strengthened by every repetition of the series in the old order, till eventually, if often fulfilled and never falsified, it becomes vivid and, as we commonly say, irresistible. To have a clear case of expectation, then, it is not necessary that we should distinctly remember any previous experience like it, but only that we should have actually presented some earlier member of a series which has been firmly associated by such previous experiences, the remaining members, or at least the next, if they continue serial, being revived through that which is once again realized. This expectation may be instantly checked by reflection, just as it may, of course, be disappointed in fact; but these are matters which do not concern the inquiry as to the nature of expectation while expectation lasts.

We shall continue this inquiry to most advantage by widening it into an examination of the distinction of present, past and future. To a being whose presentations never passed through the transitions which ours undergo—first divested of the strength and vividness of impressions, again reinvested with them and brought back from the faintest world of ideas—the sharp contrasts of “now” and “then,” and all the manifold emotions they occasion, would be quite unknown. Even we, so far as we confine our activity and attention to ideas are almost without them. Time-order, succession, antecedence, and consequence, of course, there might be still, but in that sense of events as “past and gone for ever,” which is one of the melancholy factors in our life; and in the obligation to wait and work in hope or dread to what is “still to come” there is much more than time-order. It is to presentations in their primary stage, to impressions, that we owe what real difference we find between now and then, whether prospective or retrospective, as it is to them also that we directly owe our sense of the real, of what is and exists as opposed to the non-existent that is not. But the present alone and life in a succession of presents, or, in other words, continuous occupation with impressions, give us no knowledge of the present as present. This we first obtain when our present consciousness consists partly of memories or partly of expectations as well. An event expected differs from a like event remembered chiefly in two ways—in its relation to present impressions and images and in the active attitude to which it leads. The diverse feelings that accompany our intuitions of time and contribute so largely to their colouring are mainly consequences of these differences. Let us take a series of simple and familiar events A B C D E, representing ideas by small letters, and perceptions by capitals whenever it is necessary to distinguish them. Such series may be present in consciousness in such wise that a b c d e are imaged while E is perceived anew, i.e. the whole symbolized as proposed would be a b c d e; such would be, e.g. the state of a dog that had just finished his daily meal. Again, there may be a fresh impression of A which revives b c d e; we should then (1) A b c d e—the state of our dog when he next day gets sight of the dish in which his food is brought to him. A little later we may have (2) a b c d e. Here a b are either after-sensations or primary memory-images, which we may, at any rate the increased intensity due to recent impression; but this increased intensity will be rapidly on the wane even while C lasts, and a b will pale still further when C gives place to D, and we have (3) a b c d e. But, returning to (2), we should find d e to be increasing in intensity and definiteness, as compared with their state in (1), now that C, instead of A, is the present impression. For, when A occupied this position, not only was e raised less prominently above the threshold of consciousness by reason of its greater distance from A in the memory-continuum, but, owing to the reduplications of this continuum, more lines of possible revival were opened up, to be successively negatived as B succeeded to A and C to B; even dogs know that “there is many a slip ‘twixt the cup and the lip.” But, where A B C D E is a series of percepts such as we have here supposed—and a series of simpler states would hardly afford much ground for the distinctions of past, present and future—there would be a varying amount of active adjustment of sense-organ and other movements supplemery to full perception. In (2), the point at which we have a b c d e, for instance, such adjustments and movements as were appropriate to b would cease as B lapsed and be replaced by those appropriate to C. Again, as C succeeded to B, and d in consequence increased in intensity and definiteness, the movements adapted to the reception of D would become nascent, and so on. Thus, psychologically regarded, the distinction of past and future and what we might call the oneness of direction of time depend, as just described, (1) upon the continuous sinking of the primary memory-images on the one side, and the continuous rising of the ordinary images on the other side, of that member of a series of percepts then repeating which is actual at the moment; and (2) on the prevenient adjustments of attention, to which such words as “expect,” “await,” “anticipate,” all testify by their etymology. These conditions in turn will be found to depend upon all that is implied in the formation of the memory-train and upon that recurrence of like series of impressions which we

1 Any full discussion of paramnesia, as these very interesting states of mind are called, belongs to mental pathology.

2 As, e.g. James Mill (Analysis of the Human Mind, ch. x.), who treats this difficult subject with great acuteness and thoroughness.
attribute to the “uniformity of nature.” If we never had the same series of impressions twice, knowledge of time would be impossible, as indeed would knowledge of any sort.

28. Time is often figuratively represented as a line, and we may perhaps utilize this figure to make clear the relation of our perception of time to what we call time itself. The present, though conceived as a point or instant of time, is still such that we actually can and do in that moment attend to a plurality of presentations to which we might otherwise have attended to severally in successive moments. Granting this implication of simultaneity and succession, we may, if we represent succession as a line, represent simultaneity as a second line at right angles to the first; pure time—or time-length without time-breadth, we may say—is a mere abstraction. Now it is with the former line that we have to do in treating of time as it is (or as we conceive it), and with the latter in treating of our perception of time, where, just as in a perspective representation of distance, we are confined to lines in a plane at right angles to the actual line of depth. In a succession of events $A \, B \, C \, D \, E \ldots$ the presence of $B$ means the absence of $A$ and of $C$, but the presentation of this succession involves the simultaneous presence, in some mode or other, of two or more of the presentations $A \, B \, C \, D$. In our temporal perception, then, all that corresponds to the differences of past, present and future is presented simultaneously. To this fact the name of “specious present” or “psychical present” has been given. What we have is not a moving point or moment of objective time, but rather a moving line, the contents of which, continuously changing, simultaneously represent a portion of the line of objective succession, viz. the immediate past as still present in primary memory-images, and the immediate future as anticipated in prepercepts and nascent acts. This truism—or paradox—that all we know of succession is but an interpretation of what is really simultaneous or coexistent, we may then concisely express by saying that we are aware of time only through time-perspective, and experience shows that it is a long step from a succession of presentations to such presentation of succession. The first condition of such presentation is that we should have represented together presentations that were in the first instance attended to successively, and this we have both in the persistence of primary memory-images and in the simultaneous reproduction of longer or shorter portions of the memory-train. In a series thus secured there may be time-marks, though no time, and by these marks the series will be distinguished from other simultaneous series. To ask which is first among a number of simultaneous presentations is meaningless; one might be logically prior to another, but in time they are together and priority is either momentary or indeterminate. Nevertheless, after each distinct presentation $a$, $b$, $c$, $d$ there probably follows, as we have supposed, some trace of that movement of attention of which we are aware in passing from one presentation to another. In our present reminiscences we have, it must be allowed, little direct proof of this interposition, though there is strong indirect evidence of it in the tendency of the flow to follow the order in which the presentations were first attended to. With the movements themselves we are familiar enough, though the residua of such movements are not ordinarily conspicuous. These residua, then, are our temporal signs, and, together with the representations connected by them, constitute the memory-continuum. But temporal signs alone will not furnish all the pictorial exactness of the time-perceptive. They give us only a fixed series; but the working of oblivience, by insuring a progressive variation in our awareness of the contents and number of the series to the other, yields the effect which we call time-distance. By themselves such variations would leave us liable to confound more vivid representations in the distance with fainter ones nearer the present, but from this mistake the temporal signs save us; and, as a matter of fact, where the memory-train is imperfect such mistakes continually occur. On the other hand, where these variations are slight and imperceptible, though the memory-

---

of the other. What tells in retrospect is the series a b c d e, &c.; what tells in the wearisome present is the intervening f, g, h, &c.; or rather the original accommodation by which these temporal signs are the residue, as it were, of a former impression. The intensity of a presentation does not persist, so that in memory the residue of the most intense feeling of tedium may only be so many f's in a memory-continuum whose surviving members are few and uninteresting. But in the actual experience, say, of a wearisome sermon, when the expectation of release is continually balked and attention forced back upon a monotonous drivel of platitudes, the one impressive fact is the hearer's impatience. On the other hand, so long as we are entertained, attention is never involuntary, and there is no continually deferred expectation. Just as we are said to walk with least effort when our pace accords with the rate of swing of our legs regarded as pendulums, so in pastimes impressions succeed each other at the rate at which attention can be most easily accommodated, and are such that we attend willingly.1 We are absorbed in the present without being unwillingly confined to it; not only is there no motive for retrospect or expectation, but there is no feeling that the present endures. Each impression lasts as long as it is interesting, and must not continue to monopolize the focus of consciousness till attention is finally taken off. To be wearisome is to be monotonous. In such facts, then, we seem to have proof that our perception of duration rests ultimately upon quasi-motor acts of varying intensity, the duration of which we do not directly experience as duration at all. They do endure and their intensity is a function of their duration; but the intensity is all that we directly perceive. In other words, it is here contended that what Locke called an instant or moment — "the time of one idea in our minds without the succession of another, of one wherein therefore we perceive no succession at all" — is psychologically not "a part in duration" in that sense in which, as he says, "we cannot conceive any duration without succession" (Essay, ii. 16, 12).

But, if our experience of time depends primarily upon acts of attention to a succession of distinct objects, it would seem that time, subjectively regarded, must be discrete and not continuous. This, which is the view steadily maintained by the psychologists of Herbart's school, was implied if not stated by Locke, Berkeley and Hume. Locke hopelessly confuses time as perceived and time as conceived. In his doctrine of "impressions" and "ideas of duration" he retorts, "It is very common to object to the intelligibility of the human mind spoiled by too much subtlety in nice divisions." But Berkeley and Hume, with the mathematical discoveries of Newton and Leibnitz before them, could only protest that there was nothing answering to material "time" in our experience. At any rate, Berkeley had tried to combine with his personal psychological account the inconsistent position that "none of the distinct ideas we have of either space or time is without all manner of composition," Berkeley declares, of his own part, whenever he attempts to frame a simple idea of time, abstracted from the succession of ideas in my mind, which flows uniformly and is participated by all beings, I am lost and embraeged in inextricable difficulties. I have no notion of it at all, only I hear others say it is infinitely divisible, and speak of it in such a manner as leads me to harbour odd thoughts of my existence... Time therefore being nothing, abstracted from the succession of ideas in our minds, it follows that the duration of any limit, material, mental, or temporal, is a complex of many separate separations we may run this idea up to inferior ones, which will be perfectly divisible and indivisible... that the imagination reaches a minimum, and may raise itself to an idea of its which cannot conceive any subdivision; and which cannot be diminished without a total annihilation" (Principles of Knowledge, i. § 98).

Hume, again, is at still greater pains to show that "the idea which we form of any finite quantity is not infinitely divisible. Proper time, for instance, is not something which we can, by any process of separation, divide into coextensive parts... it is impossible to divide time in such a manner as that it be not... a mere succession of series" (Human Nature, pt. i, ch. 13, § 128). At first blush we are perhaps disposed to accept this account of our time-perception, as Wundt, e.g. does, and to regard the attribute of continuity as wholly the result of after-refection.2 It may be doubted if this is really an exact analysis of the case.

1 To this rate the "indifference point" mentioned above is obviously related. It has also been called "adequate time" or "optimal time." In fact, however, a tempo that varies with the subject-matter attended to; when effective attention is more difficult the tempo is slower than it is when attention is easy.

2 Cf. Wundt, Logik, i. 432.

Granted that the impressions to which we chiefly attend are distinct and discontinuous in their occupation of the focus of consciousness, and that, so far, the most vivid element in our time-experience is discrete; granted further that in recollection and expectation such objects are still distinct— granted, in other words, to imply that time is a mere plurality—yet there is more behind. The whole field of consciousness is not occupied by distinct objects, neither are the changes in this field discontinuous. The experimental facts above-mentioned illustrate the transition from a succession the members of which are distinctly perceived, to one in which they are indistinctly extended, and to i.e., are not discontinuous enough to be separately distinguished. Attention does not move by hops from one definite spot to another, but, as Wundt himself allows, by alternate diffusion and concentration. We have a presentation, as it were, of a series of steps, or of an ascent: We raise our attention to a certain point, and attention is gathered up; and, when attention spreads out, we have confused presentations not admitting of recognition. But, though not actually, so much, such confused presentations are represented, and so serve to bridge over the comparatively empty interval during which attention is unfocused. Thus our perception of a period of time is not comparable to so many terms in a series of finite units any more than it is of a series of discrete units. The minds of all are, accordingly, in a constant state of apprehension, and neither in the perception of a single impression, nor in the perception of a succession, they do not absolutely form one" (Psychology, i. § 180).

On the whole, then, we may conclude that our concrete time-experiences are due to the simultaneous representation of a series of definite presentations both accompanied and separated by more or fewer indefinite presentations more or less confused; that, further, the definite presentations have certain marks or temporal signs due to the movements of attention; that the rate of these movements or accommodations is approximately constant; and that each movement itself is primarily experienced as an intensity.

**Experimental Investigations concerning Memory and Association.**

30. Of the vast mass of experimental work undertaken in recent years, that relating to memory and association is probably the most important. A brief account of some of it is therefore offered at this point, by way of illustrating the character of the "new psychology."

The learning and retaining of a stanza of poetry, say, is obviously a function of many variables, such as the mode of presentation (whether the words are heard only, or heard and seen, or both heard, seen and spoken aloud), the length, familiarity with the words and ideas used, the number of repetitions, the attention given, &c. Familiarity of course implies previous learning and retaining; the first essential, therefore, in any attempt to study these processes from the beginning, is the exclusion of this factor. Accordingly Ebbinghaus, the pioneer in experiments of this kind,3 devised the new material, which is now regularly employed, namely, closed monosyllables, not themselves words, and strung together promiscuously into lines of fixed length, as never to form words: *bam*, *r1t*, *por*, *s1g*, *nef*, *gud*, &c., is arranged in 10 series in such a manner that very slight attention most persons would be able to reproduce three or four such syllables on a single reading or hearing; and by greater concentration six or seven might be so reproduced. This maximum, called sometimes the "span of prehension," has been repeatedly made the subject of special inquiry. In idiots it is found, as might be expected, remarkably low; in school children it increases rapidly between the ages of eight and fourteen, and then remains almost stationary, individual differences being small compared with the striking differences that appear when longer lines make repetitions necessary.4 This comparatively constant span of prehension is doubtless

---

1 H. Ebbinghaus, "Über das Gedächtniss: Untersuchungen zur experimentellen Psychologie" (1885).
closely connected with certain other psychical constants, such as the duration of the psychical present and of the primary memory-image, the tempo of movements of attention (§§ 28, 29), &c. There are isolated investigations of these several conditions, but the subject as a whole still awaits systematic treatment. That it is not wanting in interest is evident when we consider that if our span of prehension were enlarged, a corresponding increase in the variety and range of metre and rhyme in poetry, of "phrase" in music, and of evolution in the dance would be possible. The limits at present imposed on these and like complexities find their ultimate explanation in the constants just mentioned.

With lines of greater length than seven syllables some repetition is requisite before they can be said correctly: the number of such repetitions was found by Ebbinghaus to increase rapidly with the length of the lines to be learned. In his own case, for lines of 12, 16, 24, 36 syllables the repetitions necessary were on the average 16-6, 30, 44, 55 respectively. Thus for a line exceeding in length that of the span of prehension only about five times, he required fifty-five times as many repetitions, if we may call the single presentation of the syllables a "repetition." Substituting poetry for gibberish of equal amount, Ebbinghaus found that one-tenth the number of repetitions sufficed; the enormous saving thus effected showing how numerous and intimate are the ready-made associations that "rhyme and reason" involve. But at one and the same time to memorize five verses even of sense requires more than five times as many repetitions as the memorizing of one. Two or three lines of innumerable combinations of 12 syllables, the number of successive repetitions when several are taken together; (2) as to retention after an interval, as (a) a function of the number of repetitions previously made, and as (b) a function of the time; (3) as to the respective effects of more or less cumulating, or more or less distributing, the repetitions, on the number of these required.

1. It is at once obvious that beyond a certain point exhaustion of attention renders further repetition for a time futile; thus Ebbinghaus found 64 repetitions at one sitting of six 16-syllable nonsense verses, a task lasting some three-quarters of an hour, "was apt to bring on athenia, a sort of epileptic aura, and the like!" But keeping well within this heroic limit, a certain "law of diminishing return," to use an economic analogy, disclosed. Using as a line of 12 syllables the number of correct repetitions per hour, he found that the curve of retention of the repetitions made five times the day before is.
PSYCHOLOGY

MEMORY AND ASSOCIATION

"rhyme and reason" imply. In learning a verse backwards Ebbinghaus found a saving of 12-4 % at the time, originally taken to lead into it forwards, but, having almost as little (10-4 %) was achieved by relearning a like verse forwards, but skipping one syllable: the order of syllables, that is to say, being 1, 3, 5, . . . 15, 2, 4, . . . 16. Even when learning backwards and skipping one syllable, Ebbinghaus found a saving of 5 %. But the number of his experiments (four) was too few to give this result much value, as he fully admits. These experiments as a whole, then, might incline us to suppose that association does work in both directions, though the connexions backwards are considerably weaker. But if so the associations both ways should be alike at least in form—continuous, that is to say, backwards, c b a, as well as forwards, a b c d. The facts at present available are, however, against this. In two or three hundred experiments by Müller and Pilzke, verses of twelve syllables were repeated a set number of times in anapaestic measure—accented, that is to say, on the 3rd, 6th, 9th and 12th. After a fixed interval the subject, confronted with one of the accented syllables, mentioned any of the other syllables which he called to mind. Now the cases in which the syllable immediately following the accented syllable was repeated a few times, of which the highest was in the case in which the syllable next but one preceding was revived; the time of telling (Trefferzeit) for the latter was also shorter. This result is incompatible with the theory of continuous backward association, but it is readily explained by the fact that the group of three syllables had become one complex whole, and it shows that the tendency to restate the initial member of the group is stronger than that to restate the middle. The saving effect in Ebbinghaus's experiment is also thus explained.\(^2\) A somewhat paradoxical situation is brought to light when the method of saving and the method of telling are used together. In the experiments by Jost, mentioned above, the series of verses were repeated thirty times; after an interval of twenty-four hours one series was tested by the first method and the other by the second. Two new series were then taken: the first repeated four times, and after an interval of a minute tested by the first method; the other was then repeated in like manner, and tested after the same interval by the second method. The old series was found (by the method of saving) to require on an average 5-85 s to be repeated a first time, but the time to be alleged, in the case of telling, the new series yielded 2-7 "hits," with an average time of about 3.5 seconds for each, while the old yielded only 9 "hits," with an average time of 4.5 seconds for each. Thus one may be able to reproduce relatively little of a given subject-matter, and yet require only a few repetitions in order to learn it off anew; on the other hand, one may know relatively much, and still find many more repetitions requisite for such complete learning. The "age" of the associations is then important. Other things being equal, we may conclude that each fresh repetition effects more for old associations than for recent ones. It might be supposed that the strength of the old associations was more uniform and on the average greater than the strength of the new; so that while none of the old were far below the threshold, few, if any, were above it; whereas more of the new might be above the threshold though the majority had lapsed entirely. And the latter would certainly be the case if the subject of experiment tried to make sure of a few "hits," and paid no attention to the rest of the series. Due care was, however, taken that the ends of the experiment and trial not in this way be defeated. Also, there is ample evidence to show that the supposed greater uniformity in strength of old associations is not, in fact, the rule. We seem left, then, to conjecture that the difference is the effect of the process of assimilation working subconsciously—that psychical aspect of nervous growth which Professor James has aptly characterized by saying that "we learn to skate in summer and to swim in winter." It continually happens that we can recognize connexions that we are quite unable to reproduce. To the diminished "strength" of an association, as tested by the

---

2 There are still other forms of what seems at first sight to be a regressive association, but none that do not admit of explanation without this assumption.
method of telling, there may then quite well be an equivalent set-off in a more developed assimilation. As a seed germinates it has less latent energy, but this is replaced by greater root- and stem: similar relations may obtain when an old association is said merely to lose “strength.” On the other hand—within the range of the primary memory-image—we can often reproduce what after a longer interval we should fail to recognize. We seem warranted, then, in concluding that this conception of “association-strength,” so freely used by G. E. Müller and his co-workers, requires more analysis than it has yet received. The two factors which their methods disclose in it appear to confirm the distinction we have already made between impressions and free ideas. They help us also to understand, further, the superiority of distributed over cumulated repetition, of “inwardly digesting” over “cram.”

**Feeling.**

31. Such summary survey as these limits allow of the other elementary facts of cognition is here at an end; so far the most conspicuous factors at work have been those of what might be termed the ideational mechanism. In the higher processes of thought we have to take more account of mental activity and of the part played by language. But it seems preferable, before entering upon this, to explore also the emotional and active constituents of mind in their more elementary phases.

In our preliminary survey we have seen that psychical life consists in the main of a continuous alternation of predominantly receptive and predominantly active components. In the rest of the form experience is simply an interplay of alternations of sensation and movement. At a later stage we find that in the receptive phase ideation is added to sensation; and that in the active phase thought and fancy, or the voluntary manipulation and control of the ideational trains, are added to the voluntary manipulation and control of the movements. At this higher level also it is possible that either form of receptive consciousness may lead to either form of active: sensations may be thought into action and into the receptive sense, and ideas apart from sensations may prompt to muscular exertion. There is a further complication still: not only may either sensations or ideas lead to either muscular or mental movements, but there are occasions when a thought idea, or a muscular presentation determines other movements of either kind. In this respect, however, movements and thoughts either in themselves or through their sensational and ideational accompaniments may be regarded as pertaining to the receptive side of consciousness. With these provisos, then, the broad generalization may hold that receptive states lead through feeling to active states, and that presentations that give neither pleasure nor pain meet with no responsive action. This leads to the notion of presentations that are in themselves purely indifferent lead continually to very energetic action, often the promptest and most definite action. To this there are two answers. First, on the higher levels of psychical life presentations are of frequent occurrence in a form that is interesting as signs of, or as means to, other presentations that are more directly interesting. It is enough for the present, therefore, if it be admitted that all such indifferent presentations are without effect as often as they are not instrumental in furthering the realization of some desirable end. Secondly, a large class of movements, such as those called sensori-motor and ideo-motor, are initiated by presentations that are frequently, it must be allowed, neither pleasant nor painful. In all such cases, however, probably only an apparent exception to the principle of subjective selection. They may all be regarded as instances of another important psychological principle which we shall have to deal with more fully by and by, viz. that voluntary actions, and especially those that either only avert pain or are merely subsidiary to pleasurable giving actions, tend at length, as the effect of habit in the individual and of heredity in the race, to become “secondarily automatic,” as a result of which, mechanical, non-instructive deliberation make possible a more efficient use of present energies securing pleasurable and interesting experiences, and, like the rings of former growths in a tree, afford a basis for further advance, as old ideas take root in new presentations. Here, again, it serves for our present purpose to point it out that there is a reason in favour of supposing all such movements to have been originally initiated by feeling, as certainly very many of them were.

Of the feeling itself that intervenes between these sensory and motor presentations there is little to be said. The chief points have been already insist upon, viz. that it is not itself a presentation, but a purely subjective state, at once the effect of a change in receptive consciousness and the cause of a change in motor consciousness; hence its continual confusion with the movements, whether ideational or muscular, that are its expression, or with the sensations or ideas that are its cause. For feeling as such is, so to put it, matter of being rather than of direct knowledge; and all that we know about it we know from its antecedents or consequences in presentation.

Pure feeling, then, ranging solely between the opposite extremes of pleasure and pain, we are naturally led to inquire whether there is any corresponding contrast in the causes of feeling on the one hand, and on the other in its manifestations and effects. To begin with the first question, which we may thus formulate: What, if any, are the invariable differences characteristic of the presentations or states of mind we respectively like and dislike; or, taking account of the divergent sources of feeling—sensuous, aesthetic, intellectual, active—is there anything that we can predicate alike of all that are pleasurable and deny of all that are painful, and vice versa? It is at once evident that at least in presentations objectively regarded no such common characters will be found; if we find them anywhere it must be in some relation to the conscious subject i.e. in the fact of presentation itself. There is one important truth concerning pleasures and pains that may occur at once as an answer to our inquiry, and that is one often regarded as a fundamental law of nature; it tends to further and perfect life, and whatever is painful to disturb or destroy it. The many seeming exceptions to this law of self-conservation, as it has been called, probably all admit of explanation in conformity with it, so as to leave its substantial truth unimpeached. But this law, however stated, is too teleological to serve as a purely psychological principle, and, as generally formulated and illustrated, it takes account of matters quite outside the psychologist’s ken. We are not now concerned to know why a bitter taste e.g. is painful or the gratification of an appetite pleasant, but what marks distinctive of all painful presentations the one has and the other lacks. From a biological standpoint it may be true enough that the final cause of sexual and parental feelings is the perpetuation of the species; but this does not help us to ascertain what common character they have as actual sources of feeling for the individual. From the biological standpoint again, even the senile decadence and death of the individual may be shown to be advantageous to the race; but it would certainly be odd to describe this as advantageous to the individual; so different are the two points of view. What we are in search of, although a generalization, has reference to something much more concrete than concepts like race or life, and does not require us to go beyond the consciousness of the moment to such ulterior facts as they imply.

Were it possible it would be quite unnecessary to examine in detail every variety of pleasurable and painful consciousness in connexion with a general inquiry of this sort. It will be best to enumerate at the outset the only cases that specially call for investigation. Feeling may arise mainly from (a) single sensations or movements, including in these what recent psychologists call their tone; or it may be chiefly determined by (b) some combination or arrangement of these primary presentations—hence what might be styled the lower aesthetic feelings. We have thus among primary presentations a more material and a more formal cause or ground of feeling. The mere representation of these sources of feeling involves the idea of which is how moment; the idea of a colour of a bitter taste has not definiteness or intensity enough to produce feeling; and the ideal presentation of a harmonious arrangement of sounds or colours does not in itself differ essentially as regards the feeling it occasions from the actual presentation. When we advance to the level at which there occur ideas more complex and more highly representative, or re-representative, as Mr Spencer would say—than any we have yet considered we can again distinguish between material and formal grounds of feeling. To the first we might refer, e.g. (c) the egoistic, sympathetic, and religious feelings; this class will probably require but brief notice. The second, consisting of (d) the intellectual and (e) the higher aesthetic feelings, is psychologically more important. There is a special class of

---

1See Spencer, _Data of Ethics_, chs. i.–iv.; G. H. Schneider, _Freud und Leid des Menschenlebens_, ch. i.
feelings, which might be distinguished from all the preceding as reflex, since they arise from the memory or expectation of feelings but in fact these are largely involved in all the higher feelings, and this brief reference to them will suffice: of such hope, fear, regret are examples.

a. The quality and intensity as well as the duration and frequency of a sensation or movement all have to do with determining to what feeling it gives rise. It will be best to leave the last two out of account for a time. Apart from these, the pleasantness or painfulness of a movement appears to depend solely upon its intensity, that is to say, upon the amount of effort necessary to effect it, in such wise that a certain amount of exertion is agreeable and any excess disagreeable. Some sensations also, such as those of light and sound, are agreeable if not too intense; their pleasantness increasing with their intensity up to a certain point, on passing which the feeling rapidly changes and becomes disagreeable or even painful. Other sensations, as bitter tastes, e.g., are naturally unpleasant, however faint—those that are pleasurable enlarge the field of consciousness and introduce or agreeably increase in intensity certain organic sensations, while those that are painful contract the field of consciousness and introduce or disagreeably increase in intensity certain organic sensations. There are certain other hedonic effects due to quality, the examination of which we must for the present defer. Meanwhile as to the first point it may be suggested, as at any rate a working hypothesis, that in itself any and every simple sensation or movement is pleasurable if there is attention forthcoming adequate to its intensity. In the earliest and simplest phases of life, in which the presentation-continuum is but little differentiated, it is reasonable to suppose that variation in the intensity of presentation preponderates over changes in the quality of presentation, and that to the same extent feeling is determined by the former and not by the latter. And, whereas this dependence on intensity is invariable, there is no ground for supposing the quality of any primary present—

In the lowly organisms that absorb food directly through the skin such bitter juices as exist naturally might at once produce very violent effects—comparable, say, to scalding; and the reflexes thus produced can be described as those that save from poisoning the higher organisms, whose absorbent surfaces are internal and only guarded in this way by the organ of taste. Some light is thrown on questions of this kind by the very interesting experiments of Dr Romanes; for a general account of these see his Jelly-fish, Star-fish, and Sea-urchins, ch. ix.

This is one among many cases in which the study of a vocabulary is full of instruction to the psychologist. The reader who will be at all interested in this, and shall not be contented with the compilation of "Passive Affections," in Roget’s Thesaurus of English Words and Phrases, will find ample proof both of this general statement and of what is said above in the text. The physiological concomitants show that the physical signs of pain in the higher animals consist in such changes as a lowered and weaker pulse, reduction of the surface temperature, quickened respiration, dilatation of the iris, and the like. And so far as can be seen, these changes are the same, although the reflex of pain in the lower animals is by far the least, and in large measure its actual accompaniments, the physical side of what we have called its tone. The following is a good description of these general characteristics of feeling:

En même temps, il se fait une série de mouvements généraux de flexion, comme si l’animal cherchait à se débarrasser de la douleur. Il est intéressant de remarquer que, pour l’homme comme pour tous les animaux, on retrouve ces mêmes mouvements généraux de flexion et d’extension répondant aux sentiments différents de plaisir et de douleur. Le plaisir répond à un mouvement d’apaisement, de dilatation, d’extension. Au contraire, dans la douleur, on se rapetisse, on se ferme sur soi: c’est un mouvement général de flexion." (C. Richet, L’Homme et l’Intelligence: la douleur, p. 9).
far as continued presentation entails diminished intensity, as its continued presentation entails satisfaction the train of agreeable accompaniments ceases in which the pleasurable tone consisted. But in another way long duration and frequent repetition produce indirectly certain characteristic effects on feeling in consequence of habituation and accommodation. We may get used to a painful presentation in such wise that we cease to be conscious of it as positively disagreeable, though its cessation is at once a source of pleasure; in like manner we come to require things simply because it is painful to be without them, although their possession has long ceased to be a ground of positive enjoyment. This loss (or gain) consequent on accommodation 1 has a most important effect in changing the sources of feeling: it helps to transfer attention from mere sensations to what we may distinguish as interests.

b. Certain sensations or movements not separately unpleasant become so when presented together or in immediate succession; and contrariwise, some combinations of sensations or of movements may be such as to afford pleasure distinct from, and often greater than, any that they separately yield. Here again we find that in some cases the effect seems mainly to depend on intensity, in others mainly on quality. (i.) As instances of the former may be mentioned the pleasure afforded by any rhythmic succession of sounds or movements, of symmetrical forms and curved outlines, of gentle crescendos and diminuendos in sound, and of gradual variations of shade in colour, and the pleasantness of flickering lights, “beats” in musical notes, false time, false steps, false quantities, and the like. In all these, whenever the result is pleasurable, attention can be readily accommodated—i.e., so as to be met with in any degree; and, whenever the result is painful, attention is surprised, balked, wasted. Thus we can make more movements and with less expenditure of energy when they are rhythmic than when they are not, as the performances of a ball-room or of troops marching to music amply testify.

Of this economy we have also a striking proof in the ease with which rhythmic language is retained. (ii.) As instances of the latter may be cited those arrangements of musical tones and of colours that are called harmonious or the opposite. Harmony, however, must be taken to have a different meaning in the two cases. When two or three tones harmonize there results, as is well known, a distinct pleasure over and above any pleasure due to the tones themselves. On the other hand, tones that do not accord are unpleasant in spite of any rhythmic succession; they may have singly. Besides the negative condition of absence of beats, a musical interval to be pleasant must fulfill certain positive conditions, sufficiently expressed for our purpose by saying that two tones are pleasant when they give rise to few combination-tones, and when among these there are several that coincide, and that they are unpleasant when they give rise to many combination-tones, and when among these there are few or none that coincide. Too many tones together prevent any from being distinct. But where tones coincide the number of tones actually present is less than the number of possible tones, and there is a proportionate simplification, so to put it: more is commanded and with less effort.

An ingenious writer2 on harmony, in fact, compares the confusion of a discord to that of “trying to reckon up a sum in one’s head and failing because the numbers are too high.” A different explanation must be given of the so-called harmonies of colour. The pleasurable effect of gradations of colour or shade—to which, as Ruskin tells us, the rose owes its victorious beauty when compared with other flowers—has been already mentioned: it is rather a quantitative than a qualitative effect. What we are

---

1 It has been definitely formulated, but in physiological language, by Bain in the Law of Novelty: “No second occurrence of any great and intense stimulus, whether pleasure, pain, or mere excitement, is ever fully equal to the first, notwithstanding that full time has been given for the nerves to recover from their exhaustion” (Mind and Body, p. 51). Cf. also his Emotions and Will, 3rd ed., p. 81.

2 Preyer, Akustische Untersuchungen, p. 59.
d. Closely related to these formal intellectual feelings are certain of the higher aesthetic feelings. A reference to some of the commonplaces of aesthetic writers may be sufficient briefly to exhibit the leading characteristics of these feelings. There is a wide agreement among men in general as to what is beautiful and what is not, and it is the business of a treatise on empirical aesthetics from an analysis of these matters of fact to generalize the principles of taste—to do, in fact, for one source of pleasure and pain what we are here attempting in a meagre fashion for all. And these principles are the more important in their bearing upon the larger psychological question, because among aesthetic effects are reckoned only such as are pleasing or otherwise in themselves, apart from all recognition of utility, of possession, or of ulterior gratification of any kind whatever. Thus, if it should be objected that the intellectual satisfaction of consistency is really due to its utility, to the fact that what is incompatible and incomprehensible is of no avail for practical guidance, at least this objection will not hold against the aesthetic principle of unity in variety. In accordance with this primary maxim of art criticism, the one extreme art productions of contemporary are condemned to monotony as incapable of sustaining interest because "empty," "bald," and "poor"; at the other extreme they are condemned as too incoherent and disconnected to furnish a centre of interest. And those are held as so far praiseworthy in which a variety of elements, be they movements, forms, colours or incidents, instead of conflicting, all unite to enhance each other and to form not merely a mass but a whole. Another principle that serves to throw light on our inquiry is that which has been called the principle of economy, viz. that an effect is pleasing in proportion as it is attained by little effort and simple means. The brothers Weber in their classic work on human locomotion discovered that those movements that are aesthetically beautiful are also physiologically correct; grace and ease, in fact, are well-nigh synonymous, as Herbert Spencer points out, and illustrates by apt instances of graceful attitudes, motions and forms. The same writer, again, in seeking for a more general law underlying the current maxims of writers on composition and rhetoric is led to a special formulation of this principle as applied to style, viz. that "economy of the recipient's attention is the secret of effect."

Perhaps of all aesthetic principles the most wide-reaching, as well as practically the most important, is that which explains aesthetic effects by association. Thus, to take one example where so many are possible, the croaking of frogs and the monotonous ditty of the cuckoo owe their pleasantness, not directly to what they are in themselves, but entirely to their intimate association with spring-time and its gladness. At first it might seem, therefore, that in this principle there is nothing fresh that is relevant to our present inquiry, since a pleasure that is only due to association at once carries back the question to its sources; so that in asking why the spring, for example, is pleasant we should be returning to old ground. But this is not altogether true; aesthetic effects call up not merely ideas but ideals. A great work of art improves upon the real in two respects: it intensifies and it transfigures. It is for art to gather into one focus, cleared from dress and commonplace, the genial memories of a life-time, the instinctive memories of a race; and, where theory can only classify and arrange what it receives, art—in a measure free from the literal unities of time and place—creates and glorifies. Still art eschews the abstract and speculative; however plastic in its hands, the material wrought is always that of sense. We have already noticed more than once the power which primary presentations have to sustain vivid re-presentations, and the bearing of this on the aesthetic effects of works of art must be straightforward obvious. The notes and colours, rimes and rhythms, forms and movements, which produce the lower aesthetic feelings also serve as the means of bringing into view, and maintaining at a higher level of vividness, a wider range and flow of pleasing ideas than we can ordinarily command.

When we reach the level at which there is distinct self-consciousness (cf. § 44), we have an important class of feelings determined by the relation of the presentation of self to the other contents of consciousness. And as the knowledge of other selves advances pari passu with that of one's own self, so along with the egoistic feelings appear certain social or altruistic feelings. The two have much in common; in pride and shame, for example, account is taken of the estimate other persons form of us and of our regard for them; while, on the other hand, when we admire or despise, congratulate or pity another, we have always present to our mind a more or less definite conception of self in like circumstances. It will therefore amply serve all the ends of our present inquiry if we briefly survey the leading characteristics of some contrasted egoistic feelings, such as self-complicity and disappointment. When a man is pleased with himself, his achievements, possessions or circumstances, such pleasure is the result of a comparison of his present position in this respect with some former position or with the position of someone else. Without descending to details, we may say that two prospects are before him, and the larger and fairer is recognized as his own. Under disappointment or reverse the same two pictures may be present to his mind, but accompanied by the certainty that the better is not his or is his no more. So far, then, it might be said the contents of his consciousness are in each case the same, the whole difference lying in the different relationship to self. But this makes all the difference even to the contents of his consciousness, as we shall at once see if we consider its active side. Even the idlest and most thoughtless mind teems with intentions and expectations, and in its prosperity, like the fool in the parable, thinks to pull down its barn and build greater, to take its ease, eat, drink and be merry. The support of all this pleasing show and these far-reaching aims is, not the bare knowledge of what abundance will do, but the reflection—These many goods are mine. In mind alone final causes have a place, and the end can produce the beginning; the prospect of a summer makes the present into spring. But action is paralysed or impossible when the means evade us. In so far as a man's life consists in the abundance of the things he possesses, we see then why it wavers with these. The like holds where self-complicity or discrepancy rests on a sense of personal worth or on the honour or affection of others.

§ 32. We are now at the end of our survey of certain typical pleasurable and painful states. The answer to our inquiry which it seems to suggest is that there is pleasure in proportion as a maximum of attention is effectively exercised, and pain in proportion as such effective attention is frustrated by distractions, shocks, or incomplete and faulty adaptations, or fails of exercise, owing to the narrow-ness of the field of consciousness and the slowness and smallness of its changes. Something must be said in explanation of this formula, and certain objections that might be made to it must be considered. First of all it implies that feeling is determined partly by quantitative, or, as we might say, material conditions, and partly by conditions that are formal or qualitative. As regards the former, both the intensity or concentration of attention and its diffusion or the extent of the field of consciousness have to be taken into account. Attention, whatever else it is, is a limited quantity—

Pluribus intentus minor est ad singulam sensum—

to quote Hamilton's pet adage. Moreover, as we have seen, attention requires time. If, then, attention be distributed over too wide a field, there is a corresponding loss of intensity, and so of distinctness: we tend towards a succession of indistinguishables—indistinguishable, therefore, from no succession. We must not have more presentations in the field of consciousness than will allow of some concentration of attention: a maximum diffusion will not do. A maximum concentration, in like manner—even if there were no other objection to it—

1 Cf. Fechner, Vorschule der Aesthetik, ii. 263. Fechner's full style for it is "Prinzip der okonomischen Verwendung der Mittel oder des kleinsten Kraftmasses."
2 Essays, Scientific, Political and Speculative, vol. ii., Ess. I. and VIII.
would seem to conflict with the general conditions of consciousness, inasmuch as a single simple presentation, however intense, would admit of no differentiation, and any complex presentation is in some sort a plurality. The most effective attention, then, as regards its quantitative conditions, must lie somewhere between the two zeros of complete indifferency and complete absorption. If there be an excess of diffusion, effective attention will increase up to a certain point as concentration increases, but beyond that point will decrease if this intensification continues to increase; and vice versa, if there be an excess of concentration. But, inasmuch as these quantitative conditions involve a plurality of distinguishable presentations or changes in consciousness, the way is open for formal conditions as well. Since different presentations consort differently when above the threshold of consciousness together, one field may be wider and yet as intense as another, or intenser and yet as wide, owing to this plurality of factors.

The doctrine here developed, viz., that feeling depends on efficiency, is in the main as old as Aristotle; all that has been done is to give it a more accurately psychological expression, and to free it from the implications of the faculty theory, in which form it was expounded by Hamilton. Of possible objections there are at least two that we must anticipate, and the consideration of which will help to make the general view clearer. First, it may be urged that, according to this view, it ought to be one continuous pain to fall asleep, since in this state consciousness is rapidly restricted both as to intensity and range. This statement is entirely true as regards the intensity and substantially true as regards the range, at least of the higher consciousness: certain massive and agreeable organic sensations pertain to falling asleep, but the variety of presentations at all events grows less, and then the capacity to attend is also rapidly declining; even a slight intruding sensation entails an acute sense of strain in one sense, in place of the massive pleasure of repose throughout; and any voluntary concentration either in order to move or to think involves a like organic conflict, futile effort, and arrest of balmy ease. There is as regards the more definite constituents of the field of consciousness a close resemblance between natural sleepiness and the state of monotonous humdrum we call tedium or ennui; and yet the very same excitement that would relieve the one by dissipating the weariness of inaction would disturb the other by renewing the weariness of action: the one is comensurate with the resources of the moment, the other is not. Thus the maximum of effective attention in question is, as Aristotle would say, a maximum relative to us, but this maximum varies from a wider to a narrower field of consciousness may be a pleasurable change, if attention is more effectively engaged. Strictly speaking, however, the so-called negative pleasures of rest do not consist in a mere narrowing of the field of consciousness so much as in a change in the amount of concentration. Massive organic sensations connected with restoration take the place of the comparatively acute sensations of jaded powers forced to work. We have, then, in all cases to bear in mind this subjective relativity of all pleasurable or painful states of consciousness.

As it is impossible to say that any distinguishable presentation is absolutely simple, the hypothesis of subconsciousness would leave us free to assume that anypleasantness or unpleasantsness that cannot be explained on the score of intensity is due to some obscure harmony or discord, compatibility or incompatibility, of elements not separately discernible. But this, though tempting, is not really a very scientific procedure. If a particular presentation is pleasurable or painful in such wise as to lead to a redistribution of attention, it is reasonable to look for an explanation primarily in its connexion with the rest of the field of consciousness. Moreover, it is obvious—since what takes place in subconsciousness can only be explained in analogy with what takes place in consciousness—that, if we have an explanation for the one, we may derive a corresponding explanation for the other. If the feeling produced by what comports itself as a simple presentation cannot be explained by what is in consciousness, we should be forced to admit that some presentations are more separable simply because they are in consciousness—an inexplicable which the hypothesis of subconsciousness might push farther back but would not remove.

33. But there is still another and more serious difficulty to face. It has long been a burning question with theoretical moralists whether pleasures differ only quantitatively or differ qualitatively as well, whether psychological analysis will justify the common distinction of higher and lower pleasures or force us to recognize nothing but differences of degree, of duration, and so forth—as expounded, e.g. by Bentham, whose cynical mot, "pushpin is as good as poetry provided it be as pleasant," was long a stumbling block in the way of utilitarianism. The entire issue here is confused by an ambiguity in terms that has been already noticed: pleasure and pleasures have not the same connotation. By a pleasure or pleasures we mean some assignable presentation or presentations experienced as pleasant—it as affording pleasure; by pleasure simply is meant this subjective state of feeling itself. The former, like other objects of knowledge, admit of classification and comparison: we may distinguish them as coarse or as noble, or, if we will, as cheap and wholesome. But while the causes of feeling are manifold, the feeling itself is a subjective state, varying only in intensity and duration. The best evidence of this lies in the general character of the actions that ensue through feeling—the matter which has next to engage us. Whatever be the variety in the sources of pleasure, whatever be the moral or conventional estimate of their worthiness, if a given state of consciousness is pleasant we seek so far to retain it, if painful to be rid of it: we prefer greater pleasure before less, less pain before greater. This is, in fact, the whole meaning of preference as a psychological term. Wisdom and folly each prefer the course which the other rejects. Both courses cannot, indeed, be objectively preferable; that, however, is not a matter for psychology. But as soon as reflection begins, exceptions to this primary principle of action seem to arise continually, even though we regard the individual as a law to himself. Such exceptions, however, we may presently find to be apparent only. At any rate the principle is obviously true before reflection begins—true so long as we are dealing with actually present sources of feeling, and not with their re-presentations. But to admit this is psychologically to admit everything, at least if experience is to be genetically explained. Assuming then that we start with only quantitative variations of feeling, we have to attempt to explain the development of formal and qualitative differences in the character given to the grounds of feeling. But, if aversions and pursuits result from incommensurable states of pain and pleasure, there seems no other way of saving the unity and continuity of the subject except by speculation as to the ultimate ground of the mind's primary sensation, in its extremest form. The one position involves the other, and the more scientific course is to avoid both as far as we can.

The question, then, is: How, if action depends in the last resort on a merely quantitative difference, could it ever come about that what we call the higher sources of feeling should supersede the lower? If it is only quantity that turns the scales, where does quality come in, for we cannot say, e.g. that the astronomer experiences a greater thrill of delight when a new planet rewards his search than the hungry savage in finding a clump of pig-nuts? Tempora mutantur nos et mutamur in illis contains the answer in brief. We shall understand this answer better if we look at a parallel case, or what is really our own from another point of view. We distinguish between higher and lower forms of life: we might say there is more life in a large nation than in a small one, other things being equal, but should regard a crab as possessing not necessarily more life—ass measured by waste of tissue—but certainly as manifesting life in a higher form. How, in the evolution of the animal kingdom, do we suppose this advance to have been made? The tendency at any one moment is simply towards more life, simply towards growth; but this process of self-conservation imperceptibly but steadily modifies the self that is conserved.

The creature is bent only on filling its skin; but in doing this as easily as may be it gets a better skin to fill, and accordingly seeks to fill it differently. Though cabbage and honey are what
they were before, they have changed relatively to the grub now it has become a butterfly. So, while we are all along preferring a more pleasurable state of consciousness before a less, the content of our consciousness is continually changing; the greater pleasure still outweighs the less, but the pleasures to be weighed are either wholly different, or at least are the same for us no more. What we require then, is not that the higher pleasures shall always afford greater pleasure than the lower did, but that to advance to the level of life on which pleasure is derived from higher objects shall on the whole be more pleasurable and less painful than to remain behind. And this condition seems provided in the fact of accomodation above referred to and in the important fact that attention can be more effectively expended by what we may therefore call improvements in the form of the field of consciousness. But when all is said and done, a certain repugnance is apt to arise against any association of the differences between the higher and lower feelings with differences of quantity. Yet such repugnance is but another outcome of the common mistake of supposing that the real is obtained by pulling to pieces rather than by building up. No logical analysis—may, further, logical systems are inadequate to the fullness of things. For the rest, such aversion is wholly emotional, and has no more an intellectual element in it than has the disgust we feel on first witnessing anatomical dissections.1

Emotion and Emotional Expression.

34. We now pass from the causes of feeling to its effects. We have assumed (§ 7) that the simplest and earliest of these effects are to be found in the various bodily movements commonly described as the expression or manifestation of emotion. But in a notorious article, entitled "What is an Emotion?" Professor James attempted to turn this, the common-sense notion, upside down. Before proceeding we must, therefore, examine his alternative theory: "Common sense says: we lose our fortune, are sorry and weep; we meet a bear, are frightened and run; we are insulted by a rival, are angry and strike." But, Professor James continues, "the hypothesis here to be defended says that this order of sequence is incorrect: that the one mental state is not immediately induced by the other, but the bodily manifestations must first be interposed between, and that the more rational statement is that we feel sorry because we cry, angry because we strike, afraid because we tremble, and not that we cry, strike or tremble because we are sorry, angry or fearful, as the case may be." In a word, whereas it is commonly supposed that the emotion precedes and produces the expression, it seems here to be maintained that the expression precedes and produces the emotion. But the sequence denied in the first case is a psychological sequence, the sequence maintained in the second is a physiological sequence. The subject's experiences of the bodily expressions is here the emotion, and these are physically, not psychically, determined. "They are sensational processes," says Professor James; "processes due to inward currents set up by physical happenings." The new theory is, then, in part psychological, in part physico-physical. As to the first part, which the author calls "the vital point of the whole theory," it consists mainly in exposing the ambiguity of the phrase "bodily expression of an emotion"—a phrase which is liable to mislead us into fancying that emotion, like thought, may be antecedent to, or independent of, any expression or utterance. My fear or anger may chance to be expressive to another, but they are of necessity impressive to me. "A disembodied human emotion is a sheer nonentity." In so far as I have a certain emotion, in so far I have "the feelings of its bodily symptoms." This is true, not to say trite; but how do these symptoms arise? With this question we pass to the psychophysical side of the theory, and here it becomes perplexing, and is itself perplexed; for to this question it is driven to return two distinct and divergent answers. First, we are told that it is not the emotion that gives rise to the bodily expression, but that, on the contrary, "the bodily changes follow directly the perception of the existing fact," it being beyond doubt "that objects do excite bodily changes by a preorganised mechanism." Again: "Each emotion is," for Professor James, "a resultant of a sum of elements, and each element is caused by a physiological process of a sort already well known. The elements are all organic changes, and each of them is the reflex effect of the existing object." The old attempts at classification and description being contemptuously dismissed as belonging only to "the lowest stage of science," we are informed that now we step from a superficial to a deep order of inquiry. "The questions now are causal: 'Just what changes does this object and what changes does that object excite?' and 'How come they to excite these particular changes, and not others?'" But we have not had to wait for the James-Lange theory to raise these questions, and surely there are none that bring out its defects more glaringly. "Objects" that determine bodily changes by means of preorganised mechanism and without psychical interposition might fairly be taken to be physical objects; and indeed the whole process is expressly described as reflex. But only very slovenly physiologists talk of "objects" exciting reflexes: it is inexact even to say that sensations do so. All that reflex action requires is a stimulus. The essence of a reflex action, says Foster, "consists in the transmutation, by means of the irritable protoplasm of a nerve-cell, of afferent into efferent impulses." Let Professor James be confronted first by a chained bear and next by a bear at large: to the one object he presents a bun, and to the other a clean pair of heels; or let him first be thrilled by a Beethoven symphony and then by a Raphael Madonna. Will he now undertake to account, in terms of stimuli and their reflex effects, for the very different results of the similar "causes" in the one case, or for the similar results of the very different "causes" in the other? Such a challenge would certainly be declined, and Professor James would remind us that in his nomenclature "it is the total situation on which the reaction of the subject is made." 3 But there is just a world of difference between "object" = stimulus transformed by preorganised mechanism into an efferent discharge, and "object" = total situation to which the subject reacts. The attempt to explain emotion causally on the lines of the former meaning lands us in the conscious automaton theory, with which we have as yet no direct concern. The latter meaning, on the other hand, involves the recognition of the subject's attitude as essential to the reaction, and of this as determined by pleasure, pain or by some "interest" resting ultimately on these. Such, with scarcely an exception, has always been, and still remains, the analysis of emotion in vogue among psychologists. It brings to the fore a new category, that of worth or value, one wholly extraneous to the physiologist's domain, and repugnant to the mechanical analogies which are there in place. No doubt such a concept is attained only by reflexion, but the experiences from which it is drawn, the affective states and the conative tendencies of the subject experiencing, must have preceded. From this central standpoint alone the objective situation has a worth which explains the subject's attitude, and here alone can we find the clue which

1 "To look at anything in its elements makes it appear inferior to what it seems as a whole. Resolve the statue or the building into the stone and the laws of proportion, and no worthy causes of the former beautiful result seem now left behind. So, also, resolve a virtuous act into the passions and some quantitative law, and it seems to be rather destroyed than analysed, though after all what was there else could it be resolved into? Sir A. Grant, Aristotle's Ethics, Essay IV, "The Doctrine of the Mean," p. 210 (2nd ed.).

2 Mind (1884), iv. 188 sqq.; and, again, Principles of Psychology, ch. xiv. Very similar views were advanced independently and almost at the same time by the Danish physiologist C. Lange; hence the name James-Lange theory, by which their views are commonly known. Of Lange's work a German translation was published in 1887.

3 "Physical Basis of Emotion," Psychological Review (1894), p. 518. In this reply to critics James supposed Professor James is supposed to have modified his views: it would be nearer the truth to say that he has made admissions incompatible with them.
EMOTIONAL ACTION

will enable us to answer the questions of cause that Professor James propounded.

The experimental investigations of Mosso, Féré, Lehmann, and others have shown that the vaso-motor and such like bodily changes as are prominent in emotional excitement are present also to some extent in all forms of conscious activity. The more unwarded or indistinct the excitement, the more diffuse and the more predominant over movements that are purposive; the further assimilation, both on the cognitive and the reactive side, has advanced, the more diffusion is replaced by restriction and adaptation. The more limited the movements are that separating these faculties of voluntary activity into distinct processes, as the physiologist, for example, separates the functions of striped and unstriped muscle. Unless we are prepared to treat all activity as reflex—as the physiologist may quite well do, if he keep strictly to his own point of view to which it is most reasonable to assign the possibility of a close as so much organic sensation with which purposive movement has nothing to do. No doubt this connexion of vegetal and animal functions of the same psycho-biological terms is also obvious, though its teleological fitness is obvious.

Nevertheless, Professor James's main position is that an emotion is but a sum of organic sensations; and in order to establish this he is led to the second and very different statement which we have now to examine. Here, so far from suggesting inquiries as to the "objects" that excite emotion, his point is to maintain that in so far as the bodily cause is set up, be the means what they may, in the individual case, at least the total intention is explicit: Emotions are a certain collection of organic sensations, and such complexes are emotions: the two are not merely coexistent, they are identical. The exciting object is thus, although almost inexpressive itself, yet somehow to bring up the sensations. It cannot be psychological, "the total situation for the reacting subject," for in this sense the emotion, it is maintained, may be "objectless." In support of his position Professor James quotes a case in which a physician, who was not warranted in separating these faculties of voluntary action into distinct processes, as the physiologist, for example, separates the functions of striped and unstriped muscle.

Next follows up these with accounts of other cases in which emotional apathy seemed to keep pace with sensory anaesthesia, arguing that, according to his theory, a subject absolutely anaesthetic should also be incapable of emotion, although "emotions may be objects"-that is to say, the bodily expression may be held psychological. Whether any testimony from lunatics, hypnotics and other minds diseased could suffice to establish this novel doctrine is questionable: the experience that the body of the subject is under control, Professor James, himself seems to allow. There are some four or five of the apathetic cases altogether; three of them are regarded by the mental pathologists who describe them as adverse to Professor James's theory. Of the fourth, foreseen by a psychologist on Professor James's side, the latter himself candidly observes, "We must remember that the patient's inanition may have been a co-ordinate result with the anaesthesia of his neural lesions, and not the anaesthesia's mere effect." This missing link in the argument is supplied by the experiments of Professor Sherrington, and these show conclusively that normal emotional states are possible along with complete visceral anaesthesia. As to emotional excitement induced by intoxication: Professor James and Professor James's friend Féré-who professed to objectless emotion—have both said that the object may be vague, ill-defined and shifting, but not that it is absent altogether. States of physical exaltation, depression or irritability readily aroused by association appropriate to the occasion, are of course possible; but it would seem that the least we can say is that there is no object, and then we must add that there is also no emotion.

Emotional Reaction and Conative Action.

As in dealing with the causes of feeling, so we may now in like manner proceed to inquire whether in its manifestations or effects there is any contrast corresponding to the opposing extremes of pleasure and pain. We have already seen reasons for dismissing reflex movements or movements not determined by feeling as psychologically secondary, the effects of habit and heredity, and for regarding these purely human movements the more nearly they approximate to the primitive emotion of feeling as primordial—such movements as are strictly purposive being gradually selected or elaborated from them. But some distinction is called for among the various movements expressive of emotion; for there is more in these than the direct effect of feeling regarded as merely pleasure or pain. It has been usual with psychologists to confound emotions with feelings, because intense feeling is essential to emotion. But, strictly speaking, a state of emotion is a complete state of mind, a psychosis, and not a psychical element, if we may so say. Thus in anger we have over and above pain a more or less definite object as its cause, and a certain characteristic reactive display—frowns, compressed lips, erect head, clenched fists, in a word, the combative attitude—as its effect, and similarly of other emotions; so that generally in the particular movements indicative of particular emotions the primary and primitive effects of feeling are overlaid by what Darwin has called serviceable associated habits. The purposive actions of an earlier stage of development become, though somewhat atrophied as it were, the emotive outlet of a later stage: in the circumstances in which our ancestors worried their enemies we only show our teeth. We must, therefore, leave aside the more complex emotional manifestations and look only to the simplest effects in order to discover any fundamental contrast between them.4

Joy finds expression in dancing, clapping the hands and meaningless laughter, and these actions are not only pleasurable in themselves but such as increase the existing pleasure. Attention is not drafted off or diverted; but rather the available resources seem reinforced, so that the old expenditure is supported as well as the new. To the pleasure on the receptive side is added pleasure on the active side. The violent contortions due to pain, on the other hand, are painful in themselves, though less intense than the pains from which they withdraw attention; they are but counter-irritants that arrest or inhibit still more painful thoughts or sensations. Thus, according to Darwin, sailors who are to be fogged sometimes take a piece of meat into the mouth in order to bite it with their utmost force, and thus to bear the pain. When in this way we take account of the immediate effects as well as of the causes of feeling, we find it still more strikingly true that only in pleasurable states is there an adequate expenditure of attention. It is needless now to dwell upon this point, although any earlier mention of it would hardly have been in place. But we should fail to realize the contrast between the motor effects of pleasure and of pain if we merely regarded them as cases of diffusion. The intenser the feeling, the more the parts of the body are affected; this is, whether it be smiles or tears, jumping for joy, or writhing in agony; but in the movements consequent on pleasure the diffusion is the result of mere exuberance, an overflow of good spirits, as we sometimes say, and these movements, as already remarked, are always comical. To this, to be sure, the more exaggerated the expression of pain, on the contrary, seem but so much effort to escape from the cause of it; in them there is at least the blind purpose to flee from a definite ill, but in pleasure only the enjoyment of present fortune.

From Plato downwards psychologists and moralists have been fond of discussing the relation of pleasure and pain. It has been maintained that pain is the first and most fundamental fact, and pleasure nothing but relief from pain; and, again, on the other side, that pleasure is prior and positive, and pain only the negation of pleasure. So far as the mere change goes, it is obviously true that the diminution of pain is pro tanto pleasant, and the diminution of pleasure pro tanto unpleasant; and if relativity had the fullness of the universality of the term, it is true that the two could not be said. But we must sooner or later recognize the existence of a comparatively fixed neutral state, deviations from which, of comparatively short duration and of sufficient intensity, constitute distinct states of pleasure or pain. Such states, if of liminal intensity, may then be further diminished without reversing

2 G. H. J. Berkely, "Two Cases of General Cutaneous and Sensory Anaesthesia without marked Psychical Implications," Brain (1891), xxiv. 561-564.
4 Of the three principles Darwin advances in explanation of emotional expression, the first is that of the "objects," by which he means actions which we recognize as expressive of certain states of mind are the direct result of the constitution of the nervous system, and have been from the first independent of the will, and to a large extent of habit (Expression and the Emotions, p. 66). It is in illustration of this principle too that Darwin describes the motions expressive of joy and grief, emotions which in some form or other are surely the most primitive of any.
their pleasurable or painful character. The turning-point here implied may, of course, gradually change too—as a result, in fact, of the law of accommodation. Thus a long run of pleasure would raise the hedonistic zero, while—to the small extent to which accommodation pain is possible—a continuance of pain would lower it. But such admission makes no material difference where the actual feeling of the moment is alone concerned and retrospective out of the question. On the whole it seems, therefore, most reasonable to regard pleasure and pain as emerging out of a neutral state, which is prior to and distinct from both—not a state of absolute indifference, but of simple contentment, marked by no special active display. But it is by reference to such state of equilibrium or readjustment that we see most clearly the superior volitional efficacy of pain upon which pessimists love to descant. "Not without reason," says Von Hartmann, "who had to choose between no taste at all for ten minutes or five minutes of a pleasant taste and then five minutes of an unpleasant taste, would prefer the last." Most men and all the lower animals are content to let well alone.

To ascertain the origin and progress of purposive action it seems, then, that we must look to the effects of pain rather than to those of pleasure. It is true that psychologists do not infrequently describe the earliest purposive movements as appetitive; or at least they treat appetitive and aversive movements as co-ordinate and equally primitive, pleasures being supposed to lead to actions for the purpose of as much as pains to actions for their removal. No doubt, the demand that there be a connection between a pleasureable sensation and the appropriate action is completely established, as in the case of imbibing food, the whole process is then self-sustaining till satiety begins. But the point is that such facility was first acquired under the teaching of pain—the pain of unsatisfied hunger. The term "appetite" is apt both by its etymology and its later associations to be misleading. What are properly called the "instinctive" appetites are—when regarded from their active side—movements determined by some existing uneasy sensation. So far as their earliest manifestation in a particular individual is concerned, this urgency seems almost entirely of the nature of a vis a tergo; and the movements are only more definite than those simply expressive of pain because of inherited pre-adaptation, on which account, of course, they are called "instinctive." But what one inherits another must have acquired, and we have agreed here to leave heredity on one side and consider only the original evolution.

But if none but psychological causes were at work this evolution would be very long and in its early stages very uncertain. At the same time, however, movements ensue, we may fairly suppose both that the chances of the occurrence of a pain would be small and that the number of chances, the force for repentance, would also be small. Under such circumstances natural selection would have to do almost everything and subjective selection almost nothing. So far as natural selection worked, we should have, not the individual subject making a series of tries and perfecting itself by practice, as in learning to dance or swim, but we should have those individuals whose structure happened to vary for the better surviving, increasing and displacing the rest. How much natural selection, apparently unaided, can accomplish in the way of complicated adjustment we see in the adaptation of the form and colour of plants and animals to their environment. Both factors, in reality, operate at once, and it would be hard to fix a limit to either, though to our minds natural selection seems to lose in comparative importance as we advance towards the higher stages of life.

But psychologically we have primarily to consider subjective selection, i.e. first of all, the association of particular movements with particular sensations through the mediation of feeling. The sensations here connected are mainly painful excitations from the environment, the recognised pains of locomotion, weariness, &c., and pleasurable sensations due to the satisfaction of these organic wants—pleasures which, although not a mere "filling-up," as Plato at one time contended, are still preceded by pain, but imply over and above the removal of this a certain surplus of positive good. There seem only a few points to notice. (a) When the movements that ensue through pleasure are themselves pleasurable there is ordinarily no ground for singing out any one; such movements simply enhance the general enjoyment, which is complete in itself and so far contains no hint of anything beyond. (b) Should one of these spontaneous movements of pleasure chance to cause pain, no doubt such movement is specifically arrested. Probably the most immediate connexion possible between feeling and purposive action is that in which a painful movement leads through pain to its own suppression. But such connexion is not very fruitful of consequences, inasmuch as it only secures what we may call internal training and does little to extend the relation of the individual to its environment. (c) Out of the irregular, often conflicting movements which indirectly relieve pain some one may chance to remove the cause of it altogether. Upon this movement, the last of a tentative series, attention, released from the pain, is concentrated; and in this way the evil and the remedy become so far associated that on a recurrence of the former the many diffused movements become less, and the one purposive movement more, pronounced; the one effectual way is at length established and the others, which were but palliatives, disappear. (d) When things have advanced so far that some one definite movement is definitely represented along with the painful sensation it remedies, it is not long before a still further advance is possible and we have preventive movements. Thanks to the orderliness of things, dangers have their premonitions. After a time, therefore, we may conclude that some signal sensation revives the image of the harm that has previously flouted in its wake, and a movement—either like the first, or another that has to be selected from the random tries of fear—occurs in time to avert the impending ill. (e) In like manner, provided the cravings of appetite are felt, any signs of the presence of pleasurable objects prompt to movements for their enjoyment or appropriation. In these last cases we have action determined by percepts. The cases in which the subject is invited to action by ideas as distinct from percept require a more detailed consideration; such are the facts mainly covered by the term desire.

By the time that ideas are sufficiently self-sustaining to form trains that are not wholly shaped by the circumstances of the present, entirely new possibilities of action are opened up. We can desire to live again through experiences of which there is nothing actually present to remind us, and we can desire a new experience which as yet we only imagine. We often, no doubt, apply the term to the movements met with under (e) in the last paragraph: the fox in the fable is said to have formed a desire to eat grapes he viliﬁed because of his height. Again, at the other extreme and some it is usual to speak of a desire for honour, or for wealth, and the like; but such are not so much single states of mind as inclinations or habitual desires. Moreover, abstractions of this kind belong to a more advanced stage of development than that at which desire begins, and of necessity imply more complicated grounds of action than we can at present examine. The essential characteristics of desire will be more apparent if we suppose a case somewhere between these extremes. A busy man reads a novel at the close of the day, and finds himself led off by a reference to angling or tropical scenery to picture himself with his rods packed en route for Scotland, or hooked by the next steamer for the fairyland of the West Indies. Presently, while the ideas of Jamaica or ﬁshing are at least as vividly imagined as before, the fancied preparations receive a rude shock as the thought of his work recurs. Some such case we may take as typical and attempt to analyse it. First of all it is obviously true, at least of such more concrete desires, that a man at one time fails to do so at another, and that we are often so absorbed or content with the present as not to be amenable to (new) desires at all. A given x or y cannot, then, be desired as desirable per se, it is only desirable by relation to the contents of consciousness at the moment. Of what nature is this relation? (1) At the level of psychical life that we have now reached very close and complete connections have been formed between ideas and the movements necessary for their realization, so that when the idea is vividly
PSYCHOLOGY

36. Desire naturally prompts to the search for the means to its satisfaction and frequently to a mental rehearsal of various possible courses of action, their advantages and disadvantages. Thus, by the time the ideational continuum has become—mainly by the comparatively passive work of association—sufficiently developed to furnish free ideas as thinking material, motives are forthcoming for thinking to begin. It is obviously impossible to assign any precise time for this advance; like all others, it is gradual. Fitfully, in strange circumstances and under strong excitement, the lower animals give unmistakable signs that they can understand and reason. But thought as a permanent activity may be fairly said to originate in and even to depend upon the acquisition of speech. This indispensable instrument, which more than anything else enables our psychological individual to advance to the distinctly human or rational stage, consists of gestures and vocal utterances, which were originally—and, indeed, are still to a large extent—emotional expressions.

Quidquid petuit petuitur sub specie boni is their main formula. The plausibility of this doctrine rests partly upon a seemingly imperfect analysis of what strictly pertains to desire and partly on the fact that it is substantially true both of what we may call "presentation-prompted" action, which belongs to an earlier stage than desire, and of the more or less rational action that comes later. In the very moment of enjoyment it may be fairly supposed that action is sustained solely by the pleasure received and is proportional to the intensity of that pleasure. But there is here no re-presentation and no seeking; the conditions essential to desire, therefore, do not apply. Again, in rational action, where both are present, it may be true—to quote the words of an able advocate of the view here controverted—that "our character as rational beings is to desire everything exactly according to its pleasure value." But consider what such conceptions as the good, pleasure and rational action involve. Here we have foresight and calculation, regard for self as an object of permanent interest—Butler's cool self-love; but desire as such is blind, without either the present certainty of sense or the assured prevision of reason. Pleasure in the past, no doubt, has usually brought about the association between the representation of the desired object and the movement for its realization; but neither the recollection of this pleasure nor its anticipation is necessary to desire, and even when present they do not determine what urgency it will have. The best proof of this lies in certain habitual desires. Pleasures are diminished by repetition, whilst habits are strengthened by it; if the intensity of desire, therefore, were proportioned to the "pleasure value" of its gratification, the desire for renewed gratification should diminish as this pleasure grows less; but, if the present pain of restraint from action determines the intensity of desire, this should increase as the action becomes habitual. And observation seems to show that, unless prudence suggests the forcible suppression of such belated desires or the active energies themselves fail, they do in fact become more intense, although less productive of positive pleasure, as time goes on.

Intellecnon.

36. Desire naturally prompts to the search for the means to its satisfaction and frequently to a mental rehearsal of various possible courses of action, their advantages and disadvantages. Thus, by the time the ideational continuum has become—mainly by the comparatively passive work of association—sufficiently developed to furnish free ideas as thinking material, motives are forthcoming for thinking to begin. It is obviously impossible to assign any precise time for this advance; like all others, it is gradual. Fitfully, in strange circumstances and under strong excitement, the lower animals give unmistakable signs that they can understand and reason. But thought as a permanent activity may be fairly said to originate in and even to depend upon the acquisition of speech. This indispensable instrument, which more than anything else enables our psychological individual to advance to the distinctly human or rational stage, consists of gestures and vocal utterances, which were originally—and, indeed, are still to a large extent—emotional expressions. Our space will only allow us to note in what

\[\text{Feeling.}\]

Relation of Desire to Feeling. The feeling directly consequent on desire as a state of want and restraint is one of pain, and the reaction which this pain sets up may either suppress the desire or prompt to efforts to avoid or overcome the obstacles in its way. To inquire into these alternatives would lead us into the higher phases of voluntary action; but we must first consider the relation of desire to feeling more closely.

Instances are by no means wanting of very imperious desires accompanied by the clear knowledge that their gratification will be positively distasteful.\(^1\) On the other hand it is possible to recollect or picture circumstances known or believed to be intensely pleasurable without any desire for them being awakened at all: we can regret or admire without desiring. Yet there are many psychologists who maintain that desire is excited only by the prospect of the pleasure that may arise through its gratification, and that the strength of the desire is proportional to the intensity of the pleasure thus anticipated.

\(^1\) As such an instance may be cited Plato's story of Leontius, the son of Aglaeon, in Rep. iv. 439 fin.
way language when it already exists, is instrumental in the development as distinct from the communication of thought. But the function of that in general is thinking, of which language is the instrument.  

In entering upon this inquiry we are really passing one of the hardest and finest lines of the old psychology—that between sense and understanding. So long as it was the fashion to assume a multiplicity of faculties the need was less felt for a continuing connection between sensations and intellect, much as he had eyes and ears; the heterogeneity in the one case was no more puzzling than in the other. But for psychologists who do not cut the knot in the same fashion we have to consider the matter in a different relation of the two. The contrast of receptivity and activity hardly avails, for all presentation involves activity and essentially the same activity, that of attention. Nor can we well maintain that the presentation attended to different in kind, albeit such a view has been held from Plato to Hume. Most notably good nor evil prius in sensu: the blind and deaf are necessarily without some concepts that we possess. If pure being is pure nothing, pure thought is equally empty. Thoughts consists of a certain elaboration of sense and motor images. And this is true; but imagination is also, and the processes which yield the ideational train are the only processes at work in intellectual synthesis. Moreover, it would be arbitrary to say at what point the motoric image begins—so continuous are the two. No wonder, therefore, that English psychology has been prone to regard thought as only a special kind of perception—perceiving the agreement or disagreement of ideas—and the ideas themselves as mainly the products of association. Yet the ideational train of perception is the act of a man in betaking himself to a drifting tree with that of Noah in building himself an ark. In reverie, and even in understanding the communications of others, we are comparatively passive spectators of ideational appearances, non-voluntarily determined. But in thinking or "intuition," as it has been conveniently termed, there is always a search for something more or less vaguely conceived, for a clue which will be known to his sense as a quality of the thing. This is true of all associations. Thinking may be broadly described as solving a problem—finding an AX that is B. In so doing we start from a comparatively fixed central idea or intuition and work along the several diverging lines of ideas to find the AX that is B. And this is the highest description of thought is that it is discursive. Emotional excitement—and at the outset the natural man does not think much in cold-blood—quickens the flow of ideas: what seems relevant is at once confused, but the indistinct is separated from the manifest, and little interest and receives little attention. At first the control acquired is but very imperfect; the actual course of thought of even a disciplined mind falls short of the clearness, distinctness, and contrast of the logician's ideal. Familiar associations are set to hurry attention away from the proper topic, so that thought becomes not only discursive but wandering; in place of concepts of fixed and crystalline completeness, such as logic describes, we may find a congeries of ideas but imperfectly compacted into one genuine idea, subject to continual transformation and implicating much that is irrelevant and confusing.

Thus, while it is possible for thought to begin without language, just as arts may begin without tools, yet language enables us to carry the same process enormously farther. In the first place it gives us an increased command of even such comparatively concrete generic images as can be formed without it. The name of a thing or action becomes, for one who knows the name, as much an objective mark or attribute as any quality whatever can be. The form and colour of what we call an "orange" is perhaps even more intimately combined with the sound and utterance of this word than with the taste and fragrance which we regard as strictly essential to the thing. But, whereas its essential attributes often evade us, we can always command its nominal attribute, in so far as this depends upon movements of articulation. By uttering the name (or hearing it uttered) we have secured to us, in a greater or less degree, that superior vivdness and definiteness that pertain to images reinstated by impressions: our idea approximates to the fixity and independence of a concept (cf. § 21 above). With young children and uncultured minds, who, by the way, not uncommonly think aloud "to themselves," again, the name is true as well as the connotative, and those not confined to their mother-tongue or those used to an analytical handling of language at all realize. When things are thus made ours by receiving names from us and we can freely manipulate them in idea, it becomes easier mentally to bring together facts that logically belong together, and so to classify and generalize. For names set we free from the cumbersome tangibility and particularity of perception, which is confined to just what is presented here and now. But as ideas increase in generality they diminish in definiteness and unity; they not only become less pictorial and more schematic, but they become vague and unsteady as well, because formed from a number of concrete images only related as regards one or two constituents, and not assimilated as the several images of the same thing may be. The mental picture answering to the word "horse" has, so to say, body enough to remain a steady object when under attention from time to time; but that answering to the word "animal" is perhaps scarcely twice alike. The relations of things with each other are never readily recalled or steadily controlled if the names of the relations are not included. Yet the pure concrete did not give us a definite hold upon them—make them comprehensible. Once these "airy nothing" have a name, we reap again the advantages a concrete constituent affords: by its means which is relevant becomes more closely associated, and that which is irrelevant—abstracted from—falls off. When what answers to the logical connotation or meaning of a concept is in this way linked with the name, it is no longer necessary that such "matter or content" should be distinctly present in consciousness. It takes time for an image to raise its associates above the threshold; and, when all are there, there is more demand upon attention in proportion. There is thus a manifest economy in what Leibnitz happily styled "symbolic," in contrast to "intuitive" thinking. Our power of efficient attention is limited, and with words for counters we can, as Leibnitz remarks, readily perform operations involving very complex presentations, and wait till these operations are completed before realizing and spreading out the net result in step by step.

But this simile must not mislead us. In actual thinking there never is any complete separation between the symbol and the ideas symbolized: the movements of the one are never entirely suspended till those of the other are complete. "Thus," says Hume, "if, instead of saying, that in war the weaker have always recourse..."  

Footnotes:  
1 Locke, so often misrepresented, expressed this truth according to his lights in the following: "The earth will not appear painted with flowers and clouds. It is the way we have a mind to it.... Just thus it is with our understanding: all that is voluntary in our knowledge is the employing or withholding any of our faculties from this or that sort of objects or a more or less accurate survey of them." (Essays, iv. 15. 2.)  
2 Ruskin, in his Fors clavigera, relates that the sight of the word "crocodile" used to frighten him when a child so much that he could not feel at ease again till he had turned over the page it occurred.
to negotiation, we should say, that they have always recourse to conquest, the custom which we have acquired of attributing certain relations to ideas still follows the words and makes us immediately perceive the absurdity of that proposition. How intimately the two are connected is shown by the surprises that give what point there is to puns, and by the small confusion that results from the existence of homonymous terms. The question thus arises—What are the properly ideational elements concerned in thought? Over this question psychologists long waged fight as either nominalists or conceptualists. The former maintain that what is imaged in connexion with a general concept, such as triangle, is some individual triangle "taken in a certain light," while the latter maintain that an "abstract idea" is formed embodying such constituents of the several particulars as the concept connotes, but dissociated from the specific or accidental variations that distinguish one particular from another. As often happens in such controversies, each side saw the weak point in the other. The nominalists easily showed that there was no distinct abstract idea representable apart from particulars; and the conceptualists could as easily show that a particular presentation "considered in a certain light" is no longer merely a particular presentation nor yet a mere crowd of presentations. The very thing to ascertain is what this consideration in a certain light implies. Perhaps a speculard end might have been put to this controversy if either party had been driven to define more exactly what was to be understood by image or idea. Such ideas as are possible to us apart from abstraction are, as we have seen, revived percepts, not revived sensations, are complex total re-presentations made up of partial re-presentations, which may figure in other totals (cf. § 21). Reproductive imagination is so far but a faint rehearsal of actual percepts, and constructive imagination but a faint anticipation of possible percepts. In either case we are busy with elementary presentations complicated or synthesized to what are tantamount to intuitions, in so far as the forms of intuition remain in the idea, though the fact, as tested by movement, &c., is absent. The several partial re-presentations, however, which make up an idea might also be called ideas, not merely in the wide sense in which every mental object may be so called, but also in the narrower sense as secondary presentations, i.e. as distinguished from primary presentations or impressions. But such isolated images of an impression, even if possible, would no more be intuitions than the mere impression itself would be: taken alone the one would be as free of space and time as is the other. Till it is settled, therefore, whether the ideational elements concerned in conception are intuitive complexes or something answering to the ultimate elements of these, nothing further can be done.

In the case of what are specially called "concrete" as distinct from "abstract" concepts—if this rough-and-ready, but unscientific, distinction may be allowed—the idea answering to the concept differs little from an intuition, and we have already remarked that the generic image (Gemeinbild of German psychologists) constitutes the connecting link between imagination and conception. But even concerning these it is useless to ask what does one imagine in thinking, e.g. of triangle or man or colour. We never—for the sake of this very inquiry—attempt to fix our minds in this manner upon some isolated concept; in actual thinking ideas are not in consciousness alone and disjointedly, but as part of a context. When the idea "man" is present, it is present in some proposition or question, as: Man is the paragon of animals; in man there is nothing great but greatness. If it is equally present in the act of remembering or mentally verifying such statements very different constituents out of the whole complex "man" are prominent in each. Further, what is present to consciousness when a general term is understood will differ, not only with a different context, but also the longer we dwell upon it: we may either analyse its connotation or must its denotation, as the context or the cast of our minds may determine. Thus what is relevant is alone prominent, and the more summary the attention we bestow the less the full extent and intent of the concept are displayed. To the nominalist's objection, that it is impossible to imagine a man without imagining him as either tall or short, young or old, dark or light, and so forth, the conceptualist might reply that at all events percepts may be clear without being distinct, that we can recognize a tree without recognizing what kind of tree it is, and that, moreover, the objection proves too much: for, if our image is to answer exactly to fact, we must represent not only a tall or a short man, but a man of definite stature—one not merely either light or dark, but of a certain precise complexion. But the true answer is that in conceiving as such we do not necessarily imagine a man or a tree at all, any more than—if such an illustration may serve—in writing the equation to the parabola we necessarily draw a parabola as well.

The individuality of a concept is thus not to be confounded with the sensible concreteness of an intuition either distinct or indistinct, and "the pains and skill" which Locke felt were required in order to frame what he called an abstract idea are not comparable to the pains and skill that may be necessary to discriminate or decipher what is faint or fleeting. The material "framed" consists no doubt of ideas, if by this is meant that in thinking we work ultimately with the ideational continuum, but what results is never a mere intuitive complex nor yet a mere group of such. The concept or "abstract idea" only emerges when a certain intelligible relation is established among the members of such a group; and the very same intuition may furnish the material for different concepts as often as a different gesättigtes Band is drawn between them. The stuff of this bond, as we have seen, is the word, and this brings into the foreground of consciousness when necessary those elements—whether they form an intuition or not—which are relevant to the concept. Conception, then, is not identical with imagination, although the two terms are still often, and were once generally, regarded as synonymous. The same ultimate materials occur in each; but in the one they start with and retain a sensible form, in the other they are elaborated into the form which is called "intelligible."

37. The distinctive character of this intellectual synthesis lies, we have seen, in the fact that it is determined entirely by what is synthesized, whether that be the elements of a sensory presentation, the binary constituents of intuitions or general relations of whatever kind among these. It differs, therefore, in being selective from the synthesis of association, which rests upon contiguity and unites together whatever occurs together. It differs also from any synthesis, though equally voluntary in its initiation, which is determined by a purely subjective preference, since intellelution depends upon objective relations alone. Owing to the influence of logic, which has long been in a much more forward state than psychology, it has been usual to resolve intellelution into comparison, abstraction, and classification, after this fashion: ABCM and ABCN are compared, their differences M and N left out of sight, and the class notion ABC formed including both; the same process repeated with ABC and AB with higher class notion AB; and so on. But our ideational continuum is not a mere string of ideas of concrete things, least of all such concrete things as this view implies. Not till our daily lives resembles that of a museum porter receiving specimens will our higher mental activity be comparable to that of the same sort who sorts such things by the device of his own convenience and comprehension. What we perceive is a world of things in continual motion, waxing, waning, the centres of manifold changes, affecting us and apparently affected by each other, amenable to our action and, as it seems, continually interacting among themselves. Even the individual thing, as our analysis of perception has attempted to show, is not a mere sum of properties which can be taken to pieces and distributed like type, but a whole combined of parts very variously related. To understand intellelution we must look at its actual development under the impetus of practical needs.

1 Treatise of Human Nature (Green and Grose's ed.), pt. i. § vii. p. 331.
rather than to logical ideals of what it ought to be. Like other forms of purposive activity, thinking is primarily undertaken as a means to an end, and especially the end of economy. It is often easier and always quicker to manipulate ideas than to manipulate real things; to the common mind the thoughtful man is one who "uses his head to save his heels." In all the arts of life, in the growth of language and institutions, in scientific explanation, and even in the speculations of philosophy, we may remark a steady simplification in the steps to a given end or conclusion, or—what is for our present inquiry the same thing—the attainment of better results with the same means. The earliest machines are the most clumsy and clumsy, the earliest speculations the most fanciful and anthropomorphic. Gradually imitation yields to invention, the natural fallacy of post hoc, ergo propter hoc to methodical induction, till what is essential and effective is realized and appreciated and what is accidental and inert is discarded and falls out of sight. In this way man advances in the construction of a complete mental clue or master key to the intricacies of the real world, but this key is still the counterpart of the world it enables us to control and explain.

To describe the process by which such insight is attained as a mere matter of abstraction deserves the stigma of "soulless blunder" which Hegel applied to it. Of course if attention is concentrated on X it must pro tanto be abstracted from Y, and such command of attention may require "some pains and skill." But to see in this invariable accompaniment of thinking its essential feature is much like the schoolboy's saying that engraving consists in cutting fine shavings out of a hard block. The great thing is to find out what are the light-bearing and fruit-bearing combinations. Moreover, thinking does not begin with a conscious abstraction of attention from recognized differences in the way logicians describe. The actual process of generalization, for the most part at all events, is much simpler. The same name is applied to different things or events because only their more salient features are perceived at all. Their differences, so far from being consciously and with effort left out of account, often cannot be observed when attention is directed to them; to the inexperienced all is gold that glitters. Thus, and as an instance of the principle of progressive differentiation already noted (§ 6), we find genera recognized before species, and the species obtained by adding on differences, not the genus by abstracting from them. Of course such vague and indefinite concepts are not at first logically general; they only become so when certain common elements are consciously noted as pertaining to presentations in other respects qualitatively different, as well as numerically distinct. But actually thinking starts from such more potential generality as is secured by the association of a generic image with a name. So far the material of thought is always general—is freed, that is, from the local and temporal and other defining marks of percepts.

38. The process of thinking itself is psychologically much better described as (1) an analysis and (2) a re-synthesis of this material already furnished by the ideational training. But to see this, hierarchies of concepts arranged like Porphyry's tree, into judgments uniting such concepts by means of a logical copula, &c., is the outcome of later reflection—mainly for technical purposes—upon thought as a completed product, and entirely presupposes all that psychology has to explain. The logical theory of the formation of concepts by generalization (or abstraction) and by determination (or concretion)—i.e. by the removal or addition of defining marks—assumes the previous existence of the very things to be formed, for these marks or attributes—X's and Y's, A's and B's—are themselves already concepts. Moreover, the act of generalizing or determining is really an act of judgment, so that the logician's account of conception presupposes judgment, while at the same time his account of judgment presupposes conception. But this is no evil; for logic does not essay to exhibit the actual genesis of thought but only an ideal for future thinking. Psychologically, however—that is to say, chronologically—the judgment is first. The growing mind, we may suppose, passes beyond simple perception when some striking peculiarity in what is at the moment perceived is a bar to its recognition. The stalking hunter is not instantly recognized as the destroying biped, because he crawls on all fours; or the scarecrow looks like him, and yet not like him, for, though it stands on two legs, it never moves. There is thus no immediate assimilation; recognition under such circumstances is in itself a judgment, involving an analysis more or less explicit. But of more account is the further judgment to which it leads, that which connects the new fact with the generic idea. Though actually complex, generic images are not explicitly known as complexes when they first enter into judgments; as the subjects of such judgments they are but starting-points for predication—It crawls; It does not move; and the like. Such impersonal judgments, according to most philosophers, are in fact the earliest; and we may reasonably suppose that by means of them our generic images have been partially analysed, and have attained to something of the distinctness and constancy of logical concepts. But the analysis is rarely complete: a certain confused and fluctuating residuum remains behind. The psychological concept merges at sundry points into those cognate with it—in other words, the continuity of the underlying memory-train still operates; only the ideal concept of logic is in all respects totus, teres, atque rotundus. Evidence of this, if it seem to any to require proof, is obtainable on all sides, and, if we could recover the first vestiges of thinking, would doubtless be more abundant still.

But, if we agree that it is through acts of judgment which successively resolve composite presentations into elements that concepts first arise, it is still very necessary to inquire more carefully what these elements are. On the one side we have the logicians to whom logic is the science of concepts and the other psychologists enumerating the various sensible properties of gold or wax—"their colour, weight, texture, &c.—as instances of such elements. In this way formal logic and sensationism, language, and psychology, are in a sense more or less black or blind out of one another. Language, which has enabled thought to advance to the level at which reflection about thought can begin, is now an obstacle in the way of a thorough analysis of it. A child or savage would speak only of "red" and "hot," but we of "redness" and "heat." They would probably say, "Swallows come when the days are lengthening and snipe when they are shortening"; we say, "Swallows are spring and snipe are winter migrants." Instead of "The sun shines and plants grow, we should say, "Sunlight is the cause of this and the other." In this way the logical concepts are reduced into substantive concepts; and the reason of this is not far to seek. Whether the subject or starting-point of our discursive thinking is actually what we perceive as a thing, or whether it be a quality, an action, or a relation, or a series of those, or in a spatial or temporal relation, or finally, a resemblance or difference in these or in other respects, it becomes by the very fact of being the central object of thought pro flanto a unity, and all that can be affirmed concerning it, to say no more as to its property or attributes, it is, as we have seen, the characteristic of every completed concept to be a fixed and independent whole, as it were, crystallized out of the still-fluid matrix of ideas. Moreover, the earliest objects of thought and the earliest concepts must naturally be those of the things that live and move about us; hence, then—to seek no deeper reason for the present—this natural tendency, which language by providing distinct names powerfully secures, to reify or personify the objects of our thought; which in the universal structure of thought, is debarred from recognizing any difference between concepts that does not affect their relations as terms in a proposition. As a consequence it drifts inevitably into that compart-mentalism of logic, that accordance among the various categories or predicables, but only of the one relation of whole and part qualitatively considered. It is thus thatucation this stage that logic begins. But ordinary, so-called formal, logic, which intends to concern itself with how things, thought only as the most general structure of thought, is debarred from recognizing any difference between concepts that does not affect their relations as terms in a proposition. As a consequence it drifts inevitably into that compart-mentalism of logic, that accordance among the various categories or predicables, but only of the one relation of whole and part qualitatively considered. It is thus that admission this stage that logic begins. But ordinary, so-called formal, logic, which intends to concern itself with how things, thought only as the most general structure of thought, is debarred from recognizing any difference between concepts that does not affect their relations as terms in a proposition. As a consequence it drifts inevitably into that compart-mentalism of logic, that accordance among the various categories or predicables, but only of the one relation of whole and part qualitatively considered.

38 See Wundt, Logik, i. 107 seq., where this process is happily styled "die kategorische Verschiebung der Begriffe."
disagreement. It certainly is possible to represent every judgment as a comparison, although the term is strictly adequate only to judgments of one kind and affords but a very artificial description of others. But for a logic mainly concerned with inferences, i.e., with all statements concerning classes—there is nothing more to be done than to ascertain agreements or disagreements; and the existence of these, if not necessarily, at least most evidently represented by spatial relational operations only implies a single or a comparison only and therefore leaves no room for differences of category. The resolution of all concepts into class concepts and of all judgments into comparisons thus go together. On this view the concept of a proposition only is so conceived as the reflection of the psychological interest in this thoroughgoing reduction of thought to a form which makes its consistency and logical concatenation conspicuously evident. But of the so-called matter of thought it tells us nothing. And, as said, there are many forms in the matter of at least equal moment, both for psychology and for epistemology; these formal logic has tended to keep out of sight.

It has generally been under the bias of such a formal or computational logic that psychologists, and especially English psychologists, have entered upon the study of mind. They have brought with them an analytic scheme which affords a ready place for sensations or "simple ideas" as the elements of thought, but none for any difference in the combinations of the elements. Sensations being in their very nature concrete, more, and less of names, if, and as Sigwart has acutely remarked, sensationalism and nominalism always go together. History would have borne him out if he had added that a purely formal logic tends in like manner to be more nominalistic.

If we are still to speak of the elements of thought, we must extend this term so as to include not only the sensory elements we are said to receive but three distinct ways in which this pure matter is combined: (1) the forms of intuition—Time and Space; (2) the real categories—Substance, Attribute, State, Act, Effect, End or Purpose, &c.—the exact determination of which is not here in place; and (3) certain formal (logical and mathematical) categories—as Unity, Difference, Identity, Likeness. These cannot be obtained by such a process of abstraction and generalization as logicians and psychologists alike have been wont to describe. They are not primarily concepts more general than all others in the sense in which animal is more general than man, but rather distinct methods of relating or synthesizing presentations. Kant, though he accepted almost unquestioned the logic and psychology current in his day, has yet not been found in his spirit and thought to be a nominalist, be it whether he was a transcendental idealist, and chiefly by the distinction he was led to make between formal and transcendental logic. In his exposition of the latter he brings to light the difference between the "functions of understanding" in synthesizing—or, as we might say, organizing—percepts into concepts and the merely analytic subsumption of abc and abd under ab—a, b, c and d being what they may. Unlike other concepts, categories as such do not in the first instance signify objects of thought, however general, but these functions of the understanding in constituting objects. In fine, they all imply some special process, and the general characteristic of the resulting products is what we have first of all to note.

Objects of Higher Order: their Analysis and Genesis.

39. By transposing a tune from one key to another we may obtain two entirely diverse aggregates of notes, and yet the melody may remain unchanged. On the other hand, by varying the order of the notes two distinct tunes may result from the same collection of tones. Sense furnishes merely the parts: whence, then, this identity of the whole in spite of their diversity, this diversity of the whole in spite of their identity? From the former the "intervals"; from the latter the difference of the several "intervals," it is replied. But the answer is insufficient; for the tune is a unity, not a mere series, and, further, with every interval the same problem recurs.

1 Cf. Hamilton: "To judge (spem, judicare) is to recognize the relation of congruence or of confliction in which two concepts, two individual things, or a concept and an individual, compared together, stand to each other" (Lectures on Logic, i. 225).

As to these it must suffice to refer to what has been already said: cf. §§ 11 and § 28.

For the interval, too, is a whole, though a simpler one; it does not necessarily change with a change of its constituents, nor remain the same as long as their distance is unaltered. Feelings and "associations," again, cannot account for the result, inasmuch as such accompaniments are not invariably present: moreover, they obviously presuppose the melody instead of producing it. Of such complex wholes or combinations—as distinct from mere aggregates or collections—there are many forms; as, for example, geometrical figures and patterns, motions and other changes, numbers, logical connexions, &c. In view of this variety it seems to strike the unprejudiced as wild to expect that "the progress of psychophysics" may disclose an explanation of such combinations conforming to the old scholastic maxim, nihil est in intellectu quod non fuerit praevis in sensu. Yet hopes of such a general aquaequiso are entertained! Meanwhile the "old psychology," at any rate, is content to regard such complex wholes as new presentations, the products, that is to say, not of a quasi-mechanical interaction of their constituents, but of intellectual synthesis.

What is here said of the combinations whereby the items of an aggregate are construed as parts of a whole holds equally of the comparisons whereby such items are related, as like or unlike, compatible or incompatible. Before either combination or comparison is possible, such items or particulars must be "given." But it is conceivable that they should be given and no intellectual synthesis ensue; such a consciousness has been happily named amentic. Whether or not it actually exists is another matter: it is a conceivable limit, and has the theoretical usefulness of limiting conceptions generally. But relative amentia suffices here. Suppose, then, we have: (a) item, a sound; (b) item, ditto; (c) item, ditto; or (d) item, blue; (e) item, green. The sensationalist, from Hume onwards, has complained that he does not find in the one case a further item: total three; nor in the other a further item: unlikeliness. After vainly seeking the living whole among the particulars he has to make it by their joint action. But whence this notion of "action"; and how, if such disjuncta membra suffice, do we so often fail of their effect, so that we cannot "see the wood for the trees"? Combinations and comparisons then, we conclude, are not given, but "grounded" on what is given, and is thus their fundamentum. Hence Meinong, who has studied the psychology of intuition with special care, has called the new presentations, due to this process of "grounding" (Fundiren), "objects of a higher order," or ideal objects. They have validity in respect of the particulars on which they are grounded, but not reality as data existing for perception alongside of such particulars.

The reader will here be reminded of Hume's distinction between knowledge and probability. His four philosophical relations, "which, depending solely upon ideas, can be the objects of knowledge and certainty—resemblance, continuity, degrees in quality and proportions in quantity or number"—are objects of higher order and ideal. The other three, which depend not upon the idea, may be absent or present even while that remains the same—namely, identity, the situations in time and place, and causation—are thus obviously not the result of grounding or noesis merely, are not ideal but empirical, and, have, that is to say, existential import. In fact, the second of these, the situations, though they may be grounded in the first, the contingent, can be put to us as to make intellectual synthesis at all: are neither ideal combinations nor ideal relations. And since such temporal and spatial situations enter into both the other two—numerical identity and causation—the mixed, a posteriori character of these is obvious. Whatever be the defects of Hume's psychology, his classification of relations is so far sound, and its epistemological importance can hardly be overrated. It is accordingly to be regretted that the term "relation" does not afford us to make these distinctions more precise. The German language, with the two terms Verhältniss and Beziehung, can do more.

G. F. Stout, Analytic Psychology, i. 50 sqq.

9 Meinong, "Ueber Gegenstand höherer Ordnung u.s.w.," Zeitshrift f. Psychologie (1890), xxi. 182 sqq. Special mention must be made of an earlier paper by C. v. Ehrenehof ("Uber Gestaltqualitaten," Veroffentlichungen f. wissen. Philosophie, 1890, pp. 249 sqq.), from which the whole subsequent discussion of this topic centres.

PSYCHOLOGY

Categories.

When we say that two "contents" are similar, and when too, that of analysis, we can, if need be, enumerate certain elements as the ground of their partial identity, and certain others as the ground of their partial diversity. We may further say that, abstracting from these last, we can regard the points of resemblance as constituting a general class to which the two contents belong as specific instances. But is how either comparison or abstraction possible? The term "content" implies a relation between functions, and we are no more justified in so far unsanctioned? Instances, of course, are familiar to every one, and we call red and orange colours, and say they resemble each other more than do red and blue. In presence of this question logical positivists and ardent logicians maintain that abstraction and resemblance (as distinct from qualitative identity) imply complexity; and surely he cannot be gainsaid. Yet there are the facts: red and blues of sorts, as such of others and as such. But if we say that no constituent parts, no assignable marks of identity or diversity, are forthcoming, such as we find when we class sugar and salt together as solid or soluble, and pronounce them like in colour and unlike in taste. Here the logical positivist, a-hedonist, have their counterparts—here for the percipient's consciousness at all events—they have not. We cannot "consider and attend to either the sameness or the differences in " red and blue, as we can to the like or the unlike properties in salt and sugar. None of our sensations is of the idea of a property that makes sensations simple. We are often struck by the likeness of complex wholes—two faces, say—long before we can discern the exact points of resemblance. Still, so long as there is no perceptible change in the manner in which the visual sensations are portrayed by the percipient, and, therefore, neither abstraction nor comparison based upon it. Can we find elsewhere the complexity that generalization and comparison invariably imply? Though colour may be regarded as a quality of special sensory faculty, sensation as such, as animal is a general term applicable alike to bird, beast and fish, it is a mistake to infer that the processes are the same because of this similarity in their products. We seem bound to distinguish between consciously logical or abstract processes and processes that are consciously logical or "hyponoetic," as we may perhaps call them. In the former the subjective aspect is left aside; in the latter it cannot be. The only common mark we can psychologically assign to colours is that they are all seen, and to tastes, as the elements are made up of tastes and smells; and so in the other case. So, when we talk of tasting tastes, smelling smells, feeling touches, language leads us to bear witness to this fact. When the sunset red changes to the twilight grey, I still see; but when the thunder follows the lightning, and the former is a double change, to this and not an absolute colour is transferred. And when red is pronounced liker or nearer to yellow than it is to green, this is because a smaller change is experienced in the transition from red to yellow than in that from red to green, and because in the latter yellow is reached and passed before green appears. Proximity and resemblance are, then, so far one and the same; also both are equally relative, admit of the same indefinite gradation, and have the same limit in zero, regarded either as coincidence or identity. The conception of a "proximity" is between answers, then, to what we have called a "hyponoetic relation," and this is plainly distinct from the analysis of discrete complexes, with which, as said, noetic comparison is alone concerned: the one implies and the other excludes the notion of continuity and change—a fact which helps still further to distinguish the two.

Categories.

40. We come now to deal with the categories in more detail. To begin with what are per excellence formal categories, and among these with that which is the most fundamental: the conception of unity. "Amongst all the ideas we have," says Locke, "as there is none suggested to the mind by more ways, so there is none of such a quality as that of unity, or one. It has no shadow of variety or composition in it; every object our senses are employed about, every idea in our understandings, every thought of our minds, brings this idea along with it." But to assign a sensible origin to unity is certainly a mistake—one of a class of mistakes already more than one referred to, which consist in transferring to the data of sense all that is involved in the language necessarily used in speaking of them. The term "a sensation" no doubt carries with it the idea of unity, but the bare sensation as received brings along with it nothing but itself. And, if we consider sensory consciousness merely, we do not receive a sensation, and then another sensation, and so on "seriatim;" but we have always a continuous diversity of sensations even when these are qualitatively sharply differentiated. Moreover, if unity were an impression of sense and passively received, it would, in common with other impressions, be unanalyzable. We cannot see red as blue, but we can resolve many (parts) into one (whole), and vice versa. Unity, then, is the result of an act the occasions for which, no doubt, are at first non-voluntarily determined; but the act is still as distinct from them as is attention from the objects attended to. It is to that movement of attention already described in dealing with ideation (§ 24) that we must look as the source of this category. This same movement, in like manner, yields us temporal signs; and the complex unity formed by a combination of these is what we call number. When there is little or no difference between the field and the focus of attention, unifying an impossibility, whatever the impressions received may be. On the other hand, in some cases, and perhaps in all, we have in mind a patterned and distinct the variegated continuum of sense is shaped into intuitions of definite things and events. Also, as soon as words facilitate the control of ideas, it becomes possible to single out special aspects and relations of things as the subjects or starting-points of our discursive thinking. Thus the forms of unity are manifold: every act of intuition or thought, whatever else it is, is an act of unifying.

It is obvious that the whole field of consciousness at any moment can never be actually embraced as one. What is unified becomes thereby the focus of consciousness and so leaves an outlying field; so far unity may be held to imply plurality. But it cannot with propriety be said that in a simple act of attention the field of consciousness is analysed into two distinct parts, i.e. two unities—this (now attended to) and the other or the rest (abstracted from). For the not-this is but the rest of a continuum and not itself a whole; it is left out but not determined, as the bounding space is left out when a figure is drawn. To know two unities we must connect both together; and herein comes to light the difference between the unity which is the form of the concept or subject of discourse and the unity of a judgment. The latter is of necessity complex; the former may or may not be complex; the latter is of necessity of a different nature.

If the subject of thought is not only clear but distinct—i.e. not merely defined as a whole but having its constituents likewise more or less defined—such distinctness is due to previous judgments. At any future time these may of course be repeated; such are the analytical or explicative judgments of logic. As the mere subject of discourse it is, however, a single unity simultaneously apprehended; the relation ascertained between it and its predicate constitutes the unity of judgment, a unity which is comprehended only when its parts are successively apprehended. But, though a judgment is always a complex unity, the extent of this complexity seems at first sight to vary as the form of synthesis varies. Formal logic, as we have seen, Law of Dichotomy or Duality. by throwing the form of synthesis into the predicate has no difficulty in reducing every judgment to an S is P. But, if we at all regard the matter thought, it is certain, for example, that "It is an explosion" is less complex than "The enemy destroys the mine." The first answers one question; the second answers three. But as regards the mere complex judgment both the process of ascertaining the fact and the language in which it is expressed show that the three elements concerned in it are not synthesized at one time. We may regard one of the words here printed as one, in that by a definite act we unite a plurality of letters in our image and separate it from its neighbours: we may also regard the one word as many when we attend to the transition from one letter to another and mark each step. (§ 27, Logic, ii. § 66).
CATEGORIES

PSYCHOLOGY  595

Suppose we start from the explosion—and changes or movements are not only apt to attract attention first, but, when recognized as events and not as abstractions personified, they call for some supplementing beyond themselves—then in this case we may search for the agent at work or for the object affected, but not for both at once. Moreover, if we find either, a complete judgment at once ensues: "The enemy explodes," or "The mine is exploding." The original judgment is really due to a synthesis of these two. But, when the results of former judgments are in this manner taken up into a new judgment, a certain "condensation of thought" ensues. Of this condensation the grammatical structure of language is evidence, though logical manipulation—with great pains—obliterates it. Thus our more complex judgment would take the form—"The enemy is now mine-exploding" or "The mine is enemy-exploded," according as one or other of the simpler judgments was made first. An examination of other cases would in like manner tend to show that intellectual synthesis is always—in itself and apart from implications—a binary synthesis. Wundt, to whom belongs the merit of first explicitly stating this "law of dichotomy or duality" as the cardinal principle of discursive thinking, contrasts it with an "unfounded" or "false" synthesis. This running on continuously, he represents thus—\( A - B - C - D - \ldots \); the synthesis of thought, on the other hand, he symbolizes by forms such as the following:

\[ AB; BC; CD; AB \delta C; \delta B; &c. \]

Thus, Socrates is a philosopher; the philosopher Socrates discovered a method; the philosopher Socrates discovered the dialectical method; &c. The point is that the one thing attended to in an intellectual act is the synthesis of two ideas, and of two ideas only, because, as only one movement of attention is possible at a time, only two ideas at a time can be synthesized. In that merely associative synthesis by which the memory-continuum is produced attention moves from \( A \) to \( B \) and thence to \( C \) without any relation between \( A \) and \( B \) being attended to at all, although they must have relations, that of sequence e.g. at least.

"Difference," says Hume, "I consider rather as a negation of relation than anything real or positive. Difference is of two kinds, as opposed either to identity or resemblance. The first is called a difference of number, the other of kind." The truth seems rather to be that difference in Hume's sense of numerical difference is so far an element in all relations as all imply distinct correlatives. To this extent even identity—or at least the recognition of it—relies on difference. And every form of difference, viz., which is essential to plurality. But absolute difference (i.e. diversity) of kind may be considered tantamount not, indeed, to the negation, but at least to the absence of all formal relation. That this absolute difference—or disparateness, as we may call it—affords no ground for relations becomes evident when we consider (1) that, if we had only a plurality of absolutely different presentations, we should have no consciousness at all (cf. § 11); and (2) that we never compare—although we distinguish—presentations which seem absolutely or totally disparate, as e.g. a thunderclap and the taste of sugar, or the notion of free trade and that of the Greek accusative. All actual comparison of what is qualitatively different rests upon at least partial likeness. This being understood, it is noteworthy that the recognition of likeness is, if anything, more "real or positive" than that of likeness, and is certainly the simpler of the two. In the comparison of sensible impressions—as of two colours, two sounds, the lengths or the directions of two lines, &c.—we find it easier in some cases to have the two impressions that are compared presented together, in others to have first one presented and then the other. But either way, the essential matter is to secure the most effective presentation of their difference, which in every case is something

2 Hume's numerical difference, that to say, is really distinctness, not quantitative difference.

positive and, like any other impression, may vary in amount from bare perceptibility to the extremest distance that the continuum to which it belongs will admit. Where no difference or distance at all is perceptible there we say there is likeness or equality. Is the only outcome, then, that when we pass from \( ab \) to \( ac \) there is a change in consciousness, and that \( ab \) persists there is none? To say this is to take no account of the operations (we may symbolize them as \( ac \rightarrow ab; c \rightarrow ab \rightarrow ab \delta c \) or \( ab \rightarrow ab \delta c \)). The change of presentation (c) and absence of change (o) are not here what they are as merely passive occurrences, so to put it. This is evident from the fact that in the former there is positive presentation and in the latter no presentation at all. The relation of unlikeness, then, is distinguished from the mere "position" or fact of change by (1) the voluntary concentration of attention upon \( ab \) and \( ac \) with a view to the detection of this change as their difference, and by (2) the act, relating them through it, in that they are judged unlike to that extent. The type of comparison is such superposition of geometrical lines or figures (as, e.g. in Euclid I. iv.) : if they coincide we have concrete equality; if they do not their difference is a line or figure. All sensible comparisons conform to this type. In comparing two things it is only on the contrary to place them side by side, and passing from one to the other seek to determine not the absolute shade of the second but its shade relative to the first—in other words, we look out for contrast. We do not say of one "It is dark," for in the scale or shades it may be light, but "It is darker"; or vice versa. Where there is no distance or contrast we simply have not two impressions, and, as said—if we consider the difference by itself—no impression at all. Two coincident triangles must be perceived as one. The distinction between the two triangle thus formed by two coinciding and the single triangle rests upon something extraneous to this bare presentation of a triangle that is one and the same in both cases. The marks of this numerical distinctness may be various: they may be different temporal signs, as in reduplications of the memory-continuum; or they may be constituents peculiar to each, from which attention is for the moment abstracted, any one of which suffices to give the common or identical constituent a new setting. In general, it may be said (1) that the numerical distinctness of the related scholastic realism is secured in the absence essential to quantitative difference solely by the intellectual act which has so unified each as to retain what may serve as an individual mark; and (2) that they become related as "like" either in virtue of the active adjustment to a change of impression which their partial assimilation defeats, or in virtue of an anticipated continuance of the impression which this assimilation confirms.

It is in keeping with this analysis that we say in common speech that two things in any respect similar are so far the same. This ambiguity in the word "same," whereby it means either individual identity or indistinguishable resemblance has been often noticed, and from a logical or objective point of view justly complained of as "engendering fallacies in otherwise enlightened understandings." But apparently no one has inquired into its psychological basis, although more than one writer has admitted that the ambiguity is one "in itself not always to be avoided." It is not enough to trace the confusion to the existence of common names and to cite the many controversies on the point which are not only of this nature but are not now concerned with the conformity of thought to things or with logical analysis, but with the analysis of a psychological process. The tendency to treat presentations as if they were copies of things—the objective bias, as we may call it—is the one grand obstacle to psychological observation. Some only realize with an effort that the idea of extension is not extended; no wonder, then, if it should seem "unnatural" to maintain that the idea of two like things does not consist of two like ideas. But, assuming that both meanings of identity have a psychological justification, it will be well to distinguish

them and to examine their connexion. Perhaps we might term the one 'material identity' and the other 'individual identity'—following the analogy of expressions such as "different things but all made of the same stuff," or 'the same person entirely changed.' Thus there is unity and plurality concerned in both, and herein identity or sameness differs from singularity or mere oneness, which so far entails no relation. But the unity and the plurality are different in each, and each is in some sort the converse of the other. In the one, two different individuals partially coincide; in the other, one individual is partially different; the unity in the one case is an individual presentation, in the other is the presentation of an individual.

In material identity the unity is that of a single presentation, whether simple or complex, which enters as a common constituent into two or more others. It may be possible, of course, to individualize it, but as it emerges in a comparison it is a single presentation and nothing more. On account of this absence of individual marks this single presentation is what logicians call 'abstract'; but this is not psychologically essential. It may be a generic image which has resulted from the neutralization of individual marks, but it may equally well be a simple presentation, like red, to which such marks never belonged. We come here from a new side upon a truth which has already been expounded at length, viz. that presentations are not given to us as individuals but as changes in a continuum. Time and space—the instruments, as it were, of individualization, which are presupposed in the objective sciences—are psychologically later than this mere differentiation.

The many vexed questions that arise concerning individual identity are metaphysical rather than psychological. But it will serve to bring out the difference between the two forms of identity to note that an identification cannot be established alone by qualitative comparison; an abhii or a breach of temporal continuity will turn the flank of the strongest argument from resemblance. Moreover, resemblance itself may be fatal to identification when the law of being is change.

41. As regards the real categories, it may be said generally that they have their origin in large measure to the anthropomorphic or mythical tendency of human thought—

Real Categories. Θέματα του ὑμειον ὑμειον γνώσεως. Into the formation of these conceptions two very distinct factors enter—(1) the facts of what in the stricter sense we call "self-consciousness," and (2) certain spatial and temporal relations among our presentations themselves. On the one hand, it has to be noted that these spatial and temporal relations are but the occasion or motive—and ultimately perhaps, we may say, the warrant—for the analogical attribution to things of selfness, efficiency and design, but are not directly the source of the forms of thought that thus arise. On the other hand, it is to be noted also that such forms, although they have an independent source, would never apart from suitable material come into actual existence. If the followers of Hume err in their exclusive reliance upon "associations naturally and even necessarily generated by the order of our sensations" (J. S. Mill), the disciple of Kant errs also who relies exclusively on "the synthetic unity of apperception." The truth is that we are on the verge of error in thus sharply distinguishing the two at all; if we do so momentarily for the purpose of exposition, it becomes us here again to remember that mind grows and is not made. The use of terms like "innate," "a priori," "necessary," "formal," etc., without further qualification leads only too easily to the mistaken notion that all the mental facts so named are alike undervived and original, independent not only of experience but of each other; whereas but for the forms of intuition the forms of thought would be impossible—that is to say, we should never have a self-consciousness at all if we had not previously learnt to distinguish occupied and unoccupied space, past and present in time, and the like. But, again, it is equally true that, if we could not feel and move as well as receive impressions, and if experience did not repeat itself, we should never attain even to this level of spatial and temporal intuition. Kant shows a very lame and halting recognition of this dependence of the higher forms of thought on the lower both in his schematism of the categories, and again in correcting in his Analytic the opposition of sense and understanding as respectively receptive and active with which he set out in his Aesthetic. Still, although what are called the subjective and objective factors of real knowledge advance together, the former is in a sense always a step ahead. We find again without us the permanence, individuality, efficiency, and adaptation we have found first of all within (cf. § 20, b and d). But such primitive imputation of personality, though it facilitates a first understanding, soon proves itself faulty and begets the contradictions which have been one chief motive to philosophy. We smile at the savage who thinks a magnet must need food or the child who is puzzled that the horses in a picture remain for ever still; but few consider that underlying all common-sense thinking there lurks the same natural precipitancy. We attribute to extended things a subject which we know only as the unity of an extended things subject; we attribute to changes among these extended things what we know only when we act and suffer ourselves; and we attribute further to them in their changes a subject which is dependent on them because we are asking what they are, how they act, and why they are thus and thus, we assimilate them to ourselves, in spite of the differences which lead us by-and-by to see a gulf between mind and matter. Such instinctive analogies have, like other analogies, to be confirmed, refuted, or modified by further knowledge, i.e. by the very insight into things which these analogies have themselves made possible. That in their first form they were mythical, and that they could never have been at all unless originated in this way, are considerations that make no difference to their validity—assuming, that is, that they admit, now or hereafter, of a logical transformation which renders them objectively valid. This legitimation is, of course, the business of philosophy; we are concerned only with the psychological analysis and origin of the conceptions themselves.

42. As it must here suffice to examine one of these categories; let us take that which is the most important and central of the three, viz. causality or the relation of cause and effect, as that will necessarily throw some light upon the one we have called personal causation, or the personal character of the relations of the subject to the objects of his actions. To begin, we must distinguish three things, which, though very different, are very liable to be confused. (1) Perceiving in a definite case, e.g. that on the sun shining a stone becomes warm; we have a perception. This is a mere concrete instance of predicating the causal relation. In this there is, explicitly at all events, no statement of a general law or axiom, such as we have when we say (2) "Every event must have a cause." (3) The third is merely the statement of the original causality as presented to the mind. This again is distinct from what is on all hands allowed to be an empirical generalization, viz. (3) that such and such particular causes have invariably such and such particular effects. With the last psychology is not directly concerned at all; it has only to analyse and trace to its origin the bare conception of causation as expressed in (1) and involved in both these generalizations. Whether only some events have causes, as the notion of chance implies, whether all causes are uniform in their action or some are more variable than others, as the unavowed supposition—all this is beside the question for us.

One point in the analysis of the causal relation Hume may be said to have settled once for all: it does not rest upon or contain the intuitions of cause and effect. The two relations that Hume allowed to be perceived (or "presumed to exist"), viz. contiguity in space of the objects causally related and priority in time of the cause before the effect, are the only relations directly discernible by the senses. But even here Hume's position is not so clear as we say "The sun rises and sets," as if both were matters of direct observation then and there. But that this is not so is evident from the fact that only in some cases when one change follows upon another do we feel that the latter is caused by the former. The empirical evidence is at least as common as causal connexion. Whence the difference, then, if not from perception? Hume's answer, repeated in the main by English psychologists since, is, as all the world knows, that the difference is the result of habit: when a change a occurs in an object A, it has been frequently observed to precede a change β in another object B, this repetition determines the mind to a transition from the one to the other. It is this

1 "Treatise of Human Nature," pt. iii. § XIV, "of the idea of necessary connexion."
determination, which could not be present at first, that constitutes the third relation between these objects. This "internal impression" generated by association is then projected; for 'tis a common observation that the mind has a great propensity to spread itself over and upon its own self in a way that is not always effective. In disconnecting the original agent and a patient, than a new action appears. Action is thus a simpler notion than causation and inexplicable by means of it. It is certainly no easy problem for even philosophers to determine whether the resolution of the complex is to cease, at what point we must stop, because in the presence of an individual thing and a simple activity. At any rate, we reach such a point psychologically in the conscious subject, and there we are, the one to whom the term is to be applied immediately to discover it. 

But to convince us how fallacious this reasoning is, we need only consider that the will, being here considered as a cause, has no more a discoverable connexion with its effects than any material cause has with its proper effect. The effect is there [too] distinguishable and separable from the cause, and could not be foreseen without the experience of their constant connection (op. cit. p. 455). This is a logical analysis, not psychological; the point is that the will is not considered as a cause and distinguished from its effects, nor in fact considered at all. It is not a case of sequence between two separable impressions; for we cannot really make the indefinite regress that such logical associations as that between the connexion and its acts implies. Moreover, our activity in such is not directly presented to us: we are, being active; and further this psychological analysis will not go. There are, as we have seen, two ways in which this activity is manifested, the receptive or passive and the motor or active. There is a stricter sense (cf. § 8) and our experience of these is to project in predicating the causal relation. But halves do not make a whole; so we have no complete experience of effectuation, for the simple reason that we cannot be two things at once.

The idea of the non-logical possibility of action is added the strength of expectation—as Hume supposed—when the same effect has been found invariably to follow the same cause. Finally, when upon the basis of such associated uniformities of events we have formed our ideas, the logical necessity of reason and consequent finds a place, and so far as deduction is applicable cause and reason become interchangeable ideas.

Belief.

43. The mention of logical necessity brings us to a new topic, viz. the "objectivity" of thought and cognition generally. The psychological treatment of this topic is tantamount to an inquiry into the characteristics of the states of mind we call certainty, doubt, belief—all of which centre round the one fact of evidence. Between the certainty that a proposition is true and the belief that it is true lie all grades of uncertainty. We may know that A is sometimes B, or sometimes not; or that some at least of the conditions of B are present or absent; or the presentation of A may be too confused for distinct analysis. This is the region of probability, possibility, more or less obscurity. Leaving this aside, it will be enough to notice those cases in which certainty may be complete. With that certainty which is absolutely objective, i.e. with knowledge, psychology has no direct concern; it is for logic to furnish the criteria by which knowledge is ascertained.

Emotion and desire are frequent indirect causes of subjective certainty, in so far as they determine the constituents and the
grouping of the field of consciousness at the moment—"pack the jury" or "suborn the witnesses," as it were. But the ground of certainty is in all cases some quality or some relation of these presentations inter se. In a sense, therefore, the ground of all certainty is objective—in the sense, that of being something at least directly and immediately determined for the subject and not by it. Where certainty is mediate, one judgment is often spoken of as the ground of another; but a syllogism is still psychologically a single, though not a simple, judgment, and the certainty of it as a whole is immediate. Between the judgment A is B and the question Is A B? the difference is not one of content nor scarcely one of form: it is a difference which depends upon the effect of the proposition on the subject judging. (i.) We have this effect before us most clearly if we consider what is by common consent regarded as the type of certainty and evidence, the certainty of present sense-impressions whence it is said, "Seeing is believing." The evident is here the actual, and the "feeling conscious" of the broad daylight makes us sure that the sense of being taken fast hold of and forced to apprehend what is there. (ii.) The like is true of memory and expectation: in these also there is a sense of being tied down to what is given, whereas in mere imagination, however lively, this non-voluntary determination is absent (cf. § 26). Hume saw this at times clearly enough, as, e.g. when he says, "An idea assented to feels different from a fictitious idea that the fancy alone presents to us." But unfortunately he not only made this difference a mere difference of intensity, but spoke of belief itself as "an operation of the mind" or "manner of conception that bestowed on our ideas this additional force or vivacity." In short, Hume confounded one of the indirect causes of belief with the ground of it, and again, in describing this ground committed the бессознательное making of the mind determine the ideas instead of the ideas determine the mind. (iii.) In speaking of imagination he is clearer. The answer is easy, according to propositions that are prov'd by intuition or demonstration. In that case the person who assents not only conceives the ideas according to the proposition, but is necessarily determin'd to conceive them in that particular manner "(op. cit. p. 395). It has been often urged—as by J. S. Mill, for example—that belief is something "ultimate and primordial." No doubt it is; but so is the distinction between activity and passivity, and it is not here maintained that certainty can be analysed into something simpler, but only that it is identical with what is of the nature of passivity—objective determination. As Bain put it, "The leading fact in belief...is our primitive credulity. We begin by believing everything; whatever is is true" (Emotions and Will, 3d ed., p. 511). But the point is that in this primitive state there is no act answering to "believe" distinct from the non-voluntary attention answering to "perceive," and no reflection such as a modal term like "true" important. With eyes open in the broad daylight man may say "I am certain there is light;" he simply sees. He may by-and-by come absolutely to disbelieve much that he sees—e.g. that things are nearer when viewed through a telescope—just as he will come to disbelieve his dreams, though while they last he is certain in these too. The consistency we find it possible to establish among certain of our ideas becomes an ideal, to which we expect to find all our experience conform. Still the intuitive evidence of logical and mathematical axioms is psychologically but a new form of the actual; we are only certain that two and two make four and we are not less certain that we see things nearer through a telescope.

Presentation of Self, Self-Consciousness and Conduct. 44. The concept of self we have just seen underlying and to a great extent shaping the rest of our intellectual furniture; on this account it is at once desirable and difficult to analyse it and ascertain the conditions of its development. In attempting this we must carefully distinguish between the bare presentation of self and that reference of other presentations to it which is often called specially self-consciousness, "inner sense," or internal perception. Concerning all presentations whatever—that of self no less than the rest—it is possible to reflect, "This presentation is mine; it is my object; I am the subject attending to it." The presentation of self, then, is one presentation among others, the result, like them, of the differentiation of the original continuum. But it is obvious that this presentation must be in existence first before other presentations can be related to it. On the other hand, it is only in and by means of such relations that the concept of self is completed. We begin, therefore, with self simply as an object, and end with the concept of that object as the subject or "myself" that knows itself. The self has, of first of (a) a unique interest and (b) a certain inwardness, (c) it is an individual that (d) persists, (e) is active, and finally (f) knows itself. These several characteristics of self are intimately involved; so far as they appear at all they advance in definiteness from the lowest level of mere sentiment to those moments of highest self-consciousness in which conscience approves or condemns volition.

The earliest and to the last the most important element in self—what distinguished its place from all other sensations as that variously styled the organic sensations—vital sense, coësthesia, or somatic consciousness. This largely determines the tone of the special sensations and enters into the self-hypochondria, and characteristically that, as sometimes happens in serious nervous affections, the whole body or any part of it should lose common sensibility, the whole body or that part is at once regarded as strange and even as hostile. In some cases tendencies to such a disturbance of the rational, and absence of self leave the intellect and memory unaffected, the individual doubts his own existence or denies it altogether. Ribot cites the case of such a patient, who, declaring that he had been dead two years, thus expressed his perplexity to those he met, "En dehors de la vie réelle, matérielle, il n'est pas vrai de dire que j'ai donné la mort. Tout est mécanique chez moi et se fait inconsciemment." It is not because they accompany physiological functions essential to the efficiency of the organism as an organism, but time, and space, and the particular circumstances of their occurrence. Other objects have at the outset but a mediate interest to the subject; but they do not never become so instinctively and inseparably identified with self, nor have the same inwardness. This brings us to a new point. As soon as definite perception begins, the body as an extended thing is distinguished from its parts and ultimately divided into the variously styled the organic sensations—vital sense, coësthesia, or somatic consciousness. This largely determines the tone of the special sensations and enters into the self-hypochondria, and characteristically that, as sometimes happens in serious nervous affections, the whole body or any part of it should lose common sensibility, the whole body or that part is at once regarded as strange and even as hostile. In some cases tendencies to such a disturbance of the rational, and absence of self leave the intellect and memory unaffected, the individual doubts his own existence or denies it altogether. Ribot cites the case of such a patient, who, declaring that he had been dead two years, thus expressed his perplexity to those he met, "En dehors de la vie réelle, matérielle, il n'est pas vrai de dire que j'ai donné la mort. Tout est mécanique chez moi et se fait inconsciemment." It is not because they accompany physiological functions essential to the efficiency of the organism as an organism, but time, and space, and the particular circumstances of their occurrence. Other objects have at the outset but a mediate interest to the subject; but they do not never become so instinctively and inseparably identified with self, nor have the same inwardness. This brings us to a new point. As soon as definite perception begins, the body as an extended thing is distinguished from its parts and ultimately divided into the various.
complex and loosely compacted idea of self that they originally wrought into it, suppressing to an equal extent all the rest. Normally there is a certain equilibrium to which they return, and which, we may suppose, determines the so-called temperament, nature, character, or the various perameteric aspects, that have been continually accumulating, and which makes us tolerate and comply with the presentation of self. But even within the limits of sanity great and sudden changes of mood are possible, as, e.g., in hysterical persons or those of a "mercurial temperament," or in those who are deeply involved in passionate love, and who can stem the tide of the instincts. Beyond those limits—as the concomitant apparently of serious visceral derangements or the altered nutrition of parts of the nervous system itself—complete "alienation" may ensue. A new illusion of the inner world distinguishes itself, and we save the most elementary knowledge and skill that the old possessed, but diametrically opposed to it in tastes and disposition—obscurity, it may be, taking the place of modesty and frugality and cowardice succeeding to generosity or courage. The most convincing illustrations of the psychological growth and structure of the presentation of self on the lower levels of sensation and ideation are furnished by these melancholy spectacles of minds diseased; but it is impossible to refer to them in detail here.

Paying to the higher level of intellect, we come at length upon the concept which every intelligent being more or less distinctly forms of himself as a person, M. or N., having such and such a character, tastes and convictions, such and such a disposition, and such and such a mode of life.

The main instrument in the formation of this concept, as of others, is language, and especially the social intercourse that language makes possible. Up to this point the presentation of self has shaped the ideas it is to say that all things have been apprehended by the projection of its characteristics. But now the order is in a sense reversed: the individual advances to a fuller self-knowledge by comparing the self within with what is first discussed, the "I", or rather, the "me", which is, as indicated, it is through the "us" that we learn of the "me" (cf. § 36, note 1). Collective action for common ends is of the essence of society, and in taking counsel together for the good of his tribe each one learns also to know himself for his own good. In forming with the idea of the common weal arises the idea of happiness as distinct from momentary gratification. The extra-regarding impulses are now confronted by a reasonable self-love, and in the discussion of this wish acts according to its good—but what of thought and volition. In the first we have a distinctly active manipulation of ideas as compared with the more passive spectacle of memory and imagination. Thereby emerges a contrast between the thinker and these objects of his thought, including among them the mere generic image of self, from which he now forms this concept of self as a person. A similar, even sharper contrast also accompanies the exercise of what is very misleadingly termed "self-control." i.e., control by this personal self of the various natural affections such as lust, hate, and such and such of them in life, as external objects hindered them. It is doubtful whether the reason regulating, self is commonly regarded as definitely localized. The effort of thinking and concentrating attention upon itself is in this case too salutary a thing to be regarded as impossible with the localization of other efforts in the limbs; when we think we commonly feel also, and the emotional basis of all the most subjective and inalienable. If we speak of this latent phase of the intellect as "we excess may be, such language therein, more figurative, inasmuch as the contrasts just described are contrasts into which spatial relations do not enter.

45. The term "reflection," or internal perception is applied to that state of mind in which some particular presentation or group of presentations (x or y) is not simply in the field of consciousness, but there as consciously related to self, which is also presented at the same time. Self here may be symbolized by M, to emphasize the fact that it is in like manner an object in the field of consciousness. The relation of the two is commonly expressed by saying, "This (x or y) is my (M)'s perception, idea or volition; I (M) it is that perceive, think, will it." Self-consciousness, in the narrowest sense, as when we say "I know myself, I am conscious that I am," &c., is but a special, though the most important, instance of this internal perception; here self (M) is presented in relation to self with a difference, M'; the subject itself—at least, so we say—is an object of observation.

It has been often maintained that the difference between consciousness and reflection is not a real difference, that to know and to know that you know are the same thing considered in different aspects. But different aspects of the same thing are not the same thing, for psychology at least. Not only is it the same thing to feel and to know that you feel; but it might even be held to be a different thing still to know that you feel and to know that you know that you feel—such being the difference perhaps between ordinary reflection and psychological introspection. The difficulty of apprehending these facts and keeping them distinct seems obviously due to the necessary presence of the earlier along with the later; that is to say, we can never know that we feel without feeling. But the converse need not be true. How distinct the two states are is shown in one way by their notorious incompatibility, the direct consequence of the limitation of attention: whatever we have to do that is not altogether mechanical is ill done unless we lose ourselves in the doing of it. This mutual exclusiveness receives a further explanation from the fact so often used to discredit psychology, viz., that the so-called introspection, and indeed all reflection, are really retrospections. It is not while we are engaging in a recall that we take note of such states, but afterwards, or by momentary side glances intercepting the main interest, if this be not too absorbing.

But we require an exacter analysis of the essential fact in this retrospect—the relation of the presentation x or y to that of self or M. What we have to deal with, it will be observed, is, implicitly at least, a judgment. First of all, then, it is noteworthy that we do not consider it as the healthy functioning of the self or of acts of routine, but only by matters of interest, and, as said, generally when these are over or have ceased to be all-engrossing. Now in such cases it will be found that some effect of the preceding state which is, after a certain "mental rest," has been carried on of which, otherwise unannounced till the fight is over—such e.g. as the weariness of muscular exertion or of long concentration of attention; some pleasurable or painful after-sensation passively experienced, or an idea that has been carried over from the previous state; either intended or unexpected, or the relief from the efforts of arduous striving, making prominent the contrast of contentment and want in that particular; or, finally, the quiet retrospect and mental distance which accompanies the whole of the activity, with either regret or approve what we were and did. All such presentations of the class out of which, as we have seen, the presentation of self is built up, and so form in each case the concrete bond connecting the general image of self with its object. In this way and in this respect each is a concrete instance of what we call a state, act, affection, &c., and the judgments in which such relations to the standing presentation of self are recognized are the original and the type of all real predications. The opportunities for reflection are at first few, the materials being as it were thrust upon attention, and the resulting "percepts" are but vague. By the time, however, that a clear concept of self has been attained the self-consciousness is a certain degree of self-inspection, and as the abstract of a series of instances of such definite self-consciousness we reach the purely formal notion of a subject or pure ego. For empirical psychology this notion is ultimate; its speculative treatment falls altogether—usually under the heading "rational psychology"—to metaphysics.

46. The growth of intelect and self-consciousness reacts powerfully upon the emotional and active side of mind. To describe the various aspects of feeling and of desire that thus arise—esthetic, social and religious sentiments, e.g., pride, ambition, selfishness, sympathy, &c.—is beyond the scope of systematic psychology, and certainly quite beyond the limits of an article like the present. But at least a general résumé of the characteristics of activity on this highest or rational level is indispensable. If we are to gain any oversight in a matter of such complexity it is of the first importance to keep steadily in view, as a fundamental principle, that as the causes of feeling become more complex, internal, and representative the consequent actions change in like manner. We have noted this

1 This subject has a very wide literature. The following are specially interesting: Robie, Les Maladies de la personnalite (3rd ed., 1892); Boris Sidis and S. P. Goodrich, Multiple Personality (1905); Morton Prince, The Dissociation of a Personality (1906).
convention already in the case of the emergence of desires, and seen that desire in prompting to the search for means to its end is the critical moment of intellect (cf. § 35). But intellect does much more than devise and contrive in unquenching subservience to the impulse of the moment, like some demon of Eastern fable; even the brutes, whose cunning is on the whole of this sort, are not without traces of self-control. As motives conflict and the evils of hasty action recur to mind, deliberation succeeds to mere invention and design. In moments of leisure, the more imperious cravings being stilled, besides the rehearsal of failures or successes in the past, come longer and longer flights of imagination into the future. Both furnish material for intellectual rumination, and so we have at length (1) concepts of general and distant ends, as wealth, power, knowledge, and—self-consciousness having arisen—that concept also of the happiness or perfection of self, and (2) maxims or practical generalizations as to the best means to these ends. Instead of actions determined by the vis a tergo of blind passion we have conduct shall be determined by what is literally prudence or foresight, the pursuit of ends that are not esteemed desirable till they are judged to be good. The good, it is truly urged, is not to be identified with the pleasant, for the one implies a standard and a judgment, and the other nothing but a bare fact of feeling; thus the good is often not pleasant and the pleasant not good; in talking of the good, in short, we are passing out of the region of nature into that of character. It is so, and yet this progress is itself so far natural as to admit of psychological explanation. As already urged (§ 34), the causes of feeling change as the constituents of consciousness change; also they depend more upon the form of that consciousness as this increases in complexity. When we can deliberately range to and fro in time and circumstances, the good that is not directly pleasant may indeed be preferred to what is only pleasant while attention is confined to the pleasant and sensible; but to our psychology, this change is itself pleasant—pleasanter than its rejection would have been.

The mention of deliberation brings us to the perennial problem of "the freedom of the will." But to talk of will is to lapse into the confusions of the old faculty—psychology. As Locke long ago urged: "The question is not proper, whether the will be free, but whether a man be free," 1 in the absence of external constraint, when a man does what he likes, we say he is "externally free"; but he may still be the slave of every momentary impulse, and then it is said that he is not "internally free." It is the existence of rational human freedom that is the problem. But if such freedom is held to imply a certain sovereignty or autonomy of self over against momentary propensities and blind desires, there can obviously be no question of its existence till the passions and emotions are held in subjection and mastered by the law of action. The young child, the brute and the imbecile, even when they do as they like, have not this freedom, though they may be said to act spontaneously. A resolutely virtuous man may have more of this freedom than the man of moral disposition who often succumbs to temptation; but it is equally true that the hardened sinner has more of it than one still deterred in his evil ways by scruples of conscience. A man is internally free then, whenever the ends he pursues have his heart's approval, whether he say with Milton's Satan, "Evil be thou my good," or with Jesus, "Thy will be done." But this freedom is always within our experience a relative freedom; hence at a later time it is possible that a new and possibly more effective self may be occupied by some other phase of that empirical self which is continuously, but at no one moment completely, presented. It must then be admitted that psychological analysis in this case is not only actually imperfect, but must always remain so—long, at any rate, as all that we discern by reflection is less than all we are. But this admission does not commit us to allowing the possible existence of a liberum arbitrium indifferente, sometimes called "the life of the mind," or as Locke called it, "the real freedom of the soul," which is free from respect from absolute chance or caprice. On the other hand, the rigidly determinist position can only be psychologically justified by ignoring the activity of the experiencing subject altogether. At bottom it treats analysis of the mental for the whole as if it were determined for the whole merely and always. But motives are never merely so many quantitative forces playing upon something inert, or interacting entirely by themselves. At the level of self-consciousness especially motives are reasons and reason is itself a motive. In the blind struggle of so-called "self-regarding" impulses might be the only right; but in the light of principles or practical maxims right is the only right. 2 This superiority in position of principles is only explained by reference to the inhibiting power of attention, which alone makes deliberation possible and is essentially voluntary; that is, subjectively determined. But no, it may be objected, deliberation in such cases is just the result of painful experiences and an only possible principle of action is strong enough to restrain the impulse that would otherwise prevail. Even if this be granted, it does not prove that the subject's action is determined for and not by him; it merely states the obvious expenditure and trend of nature and is not a principle of action, such as self-love and conscience, are no more psychologically on a par with appetites and desires than thought and reason are on a par with the associations of ideas.

Relations of Body and Mind.

47. The question of subjective initiative leads us naturally to that concerning the connection of mind and organism, to which we now proceed. In development and efficiency, in the intensity and complexity of their processes, mind and brain keep invariably and exactly in line together. Striking and impressive instances of this correspondence are to be found in comparative psychology, and especially in mental pathology; but it is needless here to enlarge on a point which in the main is beyond dispute. In this correspondence lay the plasticity of the brain, the fact that the brain does not merely discharge an equally impressive disparity: we reject materialism, accordingly, while still maintaining this *psychoneural parallelism* to be a well-established fact. From this we must distinguish a second sense of parallelism founded on the disparity just mentioned as pertaining to the psychological and neural correlates. We may call this *physiological-pyschological*, or, more briefly, *methodological-parallelism*. It disclaims as illogical the attempt to penetrate to psychical facts from the standpoint of physiology, so persistently and confidently pursued by the old materialists. It also forbids the psychologist to piece out his own shortcomings with tags borrowed from the physiologist. The concepts of the two sciences are to be kept distinct, as the facts themselves to which they relate are distinct. Confusion is inevitable if the psychologist, for example, talks of his volition as the cause of his arm moving, when by arm movement he means the process described by the physiologist in terms of electron excitations, muscular flexions, and so forth; or if the physiologist speaks of a sensation of red as produced by retinal stimulation due to light-waves of a certain length, when by sensation he means what he immediately experiences on looking at a field poppy. This methodological convention, as we may call it, implies a more stringent interpretation of causation than that expounded by J. S. Mill and his contemporaries. It does not, however, forbid psychological inferences on the basis of physiological facts, nor vice versa. But in spite of this distinctness of the facts, and of the standpoints from which they are respectively studied, their causal relation cannot be simply ignored: it is, however, a problem that pertains strictly to the higher standpoint of philosophy. There have been in all four different theories of this relation within modern times: (1) that of mutual interaction—the antithesis of Locke's and Spinoza's concepts of parallel participation of the One Substance. The last of these—oversevered, however, from Spinoza's metaphysics—is still perhaps the prevailing theory, and to it the term *psychophysical parallelism* most properly applies. For whereas the parallelism first mentioned states a real correspondence between psychical processes and neural processes, but leaves open the question of a possible interaction between matter and mind, modern psychophysical parallelism is a pure hypothesis concerning the relation of psychical facts to physical theories, on the ground of which—as we shall presently see—any interaction between matter and mind is expressly denied.

The right is only relative, of course, when the maxims are "hypothetical"—to use Kant's phrase—but it is absolute when the maxim is "categorical."
But in the exposition of this hypothesis these two meanings of parallelism are frequently confused or interchanged. The same term "body" is applied both to an aggregate of matter and to the living organism. Now life must be regarded as either inherent in matter or springing from it. The former interpretation, which implies the dualism of ear, is untenable (cf. § 10), and the latter, as physically inexplicable. But, for the present at all events, it cannot be explained physically; nor are we even within measurable distance of such an explanation: so much is beyond cavil. Yet the hypothesis of psychoneural parallelism reduces us to one or other of the former alternatives: at the same time its unwarrantable identification with psychoneural parallelism—where we find a real correspondence between mind and organism—tends to conceal the gravity of this difficulty. If the physical and the psychological explanations of physical phenomena, must be described not as identical with that of physics, but as intermediate between it and the standpoint of psychology. For the fact of life could be reduced to physical terms, physiology then, no doubt, would have to be converted into life physiology, but, for example, may have had to do. On the other hand, till a physical explanation of life is forthcoming, physiology belongs, with psychology, to the biological group of sciences and cannot divert itself completely from the teleological concepts essential to them, not a vestige of which belongs to bare physics. It is just because of this community in their concepts that there actually is a certain "point to point" correspondence or parallelism between the psychical and the neural: as an organ a neuron is a unit; physically regarded, it ceases to be one. Yet this illicit identifications of organism and material body is thought to be legitimate, inasmuch as physiological processes are found to rest invariably on a physical basis: and inasmuch as, though methodologically and theoretically it is possible to identify life processes with nerve processes, no limits can be imposed on his efforts to ascertain the mechanism of the nervous it self. But if this be granted, it is not psychophysical parallelism justified, in principle at all events. By no means, indeed, that the replacement of the psychical mechanism of a locomotive would justify us in ascribing its origin, its maintenance or its guidance to the machine itself. When life and mind are explained by their mechanism the physicist may summon the biologist, as Mephistopheles did Faust, "Hier zu mir!": then, but not before.

A favourite mode of stating psychophysical parallelism is that known as the Double Aspect Theory. In this, besides the unjustified identification of the first and third meanings, we find also an equally unjustified interpretation of parallelism in the second sense. All that methodology is that psychologists and neurologists—and, we may add, that physicists too—shall severally, as "mental" and "material" or "physical" sciences, respectively, each "going along by itself." In other words, the series themselves are said to exemplify what methodology enjoins on the sciences that investigate them—they mind their own business and never intrude into each other's domains. Nevertheless their interaction is not prima facie contradictory or absurd, and ordinary thought, as we have seen, assumes that it exists. What evidence, then, is there for denying it absolutely? Empirical evidence for such a universal negative there can hardly be; it must be established therefore—if established at all—on a priori grounds. Meanwhile two facts, already noticed, make seriously against it. In its most psychical relations it is abstractions to an intrusion of some sort, and are not psychically explicable (cf. § 11). Moreover, for the present at all events—must be said of the fact of life on the physical side. Apart from all this, it seems plain that methodological parallelism, so far from justifying the denial of interaction, simply precludes its discussion on the dualistic level to which that parallelism is confined. The gulf implied is indeed not absolute—of so much, parallelism in the first sense assures us—but those who are forced to keep to their own side of it obviously are not the people to settle how it is crossed. We are aware that the dualism is not absolute, it is replied: it is only phenomenal, and the two series of phenomena are conditioned by an underlying unity of substance. Such is the second, and positive, proposition of the theory. Again asking for evidence, we are told that this underlying unity is unknown—in fact, unknowable. This unknowable substance is assumed, then, simply because the impossibility of causal connexion being taken as established—no other alternative remains. The negative proposition is thus the foundation of the theory, and without it this agnostic monism becomes entirely arbitrary. We have, therefore, to continue our search for the grounds on which the possibility of interaction is denied. But it will be worth while first to examine certain ambiguities besetting the positive statement.

Difference of aspect may result solely from difference of standpoint, or it may be due to difference in the reality itself. The circle, seen as concave from within and as convex from without, is an ancient instance of the first still in great favour; the pillar that was cloud and darkness to the Egyptians, but light to the children of Israel, may serve to exemplify the second. The former we may call the phenomenal, and the latter the ontal, meaning of "aspect." With these two very different meanings our theory plays fast and loose, as suits its own convenience. To do this is easy—in so far as the reality is unknown and unknowable; and necessary—since in the end, the reality, however unknowable, must somehow include both the phenomenal aspects and all that pertains to them, and so far therefore be known. In dealing with "aspect" in the first sense, the one question to be raised concerns the nature and relation of the respective standpoints. One belongs what we know as individual experience, and this is essentially concrete, immediate, and qualitatively diverse; to the other belongs an abstract, conceptual scheme, wholly quantitative, familiarly known as the mechanical theory. Between these there is plainly no such co-ordination as the inept comparison with the inside and the outside of a circle implies. Neither is there, on the other hand, the same complete opposition; for the entire mechanical theory is based upon individual experience as enlarged and developed by inter-subjective intercourse. Both the sense-knowledge of the one and the thought-knowledge of the other relate to the one objective factor involved in both. So far, then, there is fundamentally only one standpoint—that of the subjective factor to the objective factor, which is immediately perceived in the one and mediately conceived in the other. The question raised is thus primarily epistemological, but it is a question, as we have seen, in which psychology is intimately concerned. "Aspect" in the second sense is independent of standpoints. We have here to deal with attributes of the one reality, more or less in Spinoza's sense: this reality itself, as possessed of disparate attributes, is so far dual, and the question of causal connexion between these attributes is not escaped. For to know that a thing has invariably two distinct attributes does not enable us to determine straightforwardly how the changes or "modes" of the one are connected with those of the other.

1 The same attribute might be always the initiating or independent variant, and then would come the question of finding out which of the two it was; or (2) it might be that now one, now the other, took the lead, the grounds of this alternation being then the topic for inquiry; or, finally, (3) it might be, as our theory assumes, that there was but a single series of double changes. The questions here raised are philosophical questions, but again they are questions in which psychology is intimately concerned. They yield two results: first, there is fundamentally only one single standpoint—this experience, now at the perceptual, now at the conceptual, level; and secondly, the distinction of aspects is not merely phenomenal, but pertains "somehow" to reality. The question is how; and this leads us to resume our inquiry into the grounds on which interaction is denied.

These grounds neither pertain to psychology nor to physiology. In spite of the outstanding difficulties connected with sensation and life, which these sciences, severally raise, such denial is upheld.

1 In fact, if there were, since it is only as we contemplate finite portions of the circle that the distinction of concave and convex propounds, the mind is not thereby prevented from grasping this difference of aspect would disappear. If on the physical side we called these elements atoms, there would be an answering element of "mind-stuff" on the psychical; and there would be no more unity and no other diversity in a given man's mind than in his brain regarded as a complex of primordial atoms. Wild as all this seems, yet views of the kind have been seriously put forward more than once as the logical outcome of psychophysical parallelism.
mainly on the strength of an interpretation of the principle
known as the conservation of energy—an interpretation of it,
however, which many of the ablest physicists disallow. The
energy of the physical world, it is maintained, is a strictly
invariable amount; matter, therefore, cannot act on mind, for
such action would entail a decrease, nor can mind act on matter,
since that would entail an increase, of this energy. In other
words, the material world is held to be a "closed system";
and as all the changes within it are mass-motions, there can be
none which are not the effect and equivalent of antecedent mass-
motions. But now this statement must be established on
physical grounds: to assume it otherwise would be openly to beg
the very question at issue. For if mind does act on matter, the
physical mechanism is subject to changes from without, and so
often its motions are not due to antecedent motions; and this
—the common-sense view—cannot, of course, be summarily
dismissed as impossible or absurd. Now, energy is essentially
a metrical notion, and its conservation in finite and isolated
material systems has been ascertained by careful quantitative
experiments. To say that the energy of the material universe
is constant is only a way of expressing the generalization
of this result—is tantamount, in other words, to saying that it
holds of all finite isolated systems. The whole universe may
perhaps be called isolated, but we do not know that it is
finite. We cannot, therefore, apply metrical concepts to it; and
consequently we cannot interpret the conservation of energy as
meaning that the physical part of it is a closed system. But
if not a closed system, then the energy of a given group of bodies
may be increased or decreased without interaction between that
group and other bodies—may be increased or decreased by
psychophysical interaction, that is to say. And, moreover,
such psychophysical interaction would not invalidate the con-
servation of energy, rightly understood; for that merely means
that the energy of a group of bodies can be altered only from
without, and this might happen whenever such interaction
occurred. We seem, therefore, justified for the present in re-
jecting psychophysical parallelism as one of the three possible
modes of relating mind and matter regarded as antitheses of the
real. Not only are there psychological as well as biological
objections which it has not yet overcome, but there are so far
no physical grounds in its favour.

At this point we may again for a moment turn aside to consider
a modified form of the doctrine—the so-called Conscious Auto-
"Conscious Action Theory" or "animal Automaton Theory." According to Huxley, the best known modern
eponent of this theory, "our mental conditions are simply the symbols in consciousness of the changes that
take place automatically in the organism." This consciousness
is supposed to be related to the mechanism of the body simply as a collateral product of its working, and to
be as completely without any power of modifying that working as the steam whistle... is without influence upon
the physical energy; thus "the feeling" is a call vovation is not the cause of a volition but the symptom
of that state of the brain which is the immediate cause of
that act." In other words, physical changes are held to be
independent of psychical, whereas psychical changes are
declared to be their "collateral products." They are called
"collateral products," or "epiphenomena," to obviate the charge
of materialism, and to conform to the interpretation of the con-
servation of energy that we have just discussed. Such a theory
is, strictly speaking, one of parallelism no longer: rather it
adopts, instead, the first of the two possibilities we have noted
above as opposed to parallelism. According to it, matter is the
initiating or independent variant, on whose changes mind simply
follows suit. It is open to two fatal objections. First, it is
methodologically unsound: its psychology is physiological in the
bad sense. It regards all states of consciousness as passive,
"i.e. as ultimately either "feelings" or "reflexes." Volitional
activity is declared illusory, and if this be true, intellectual
activity must be illusory too. But to detect illusion requires
experience of reality—we only know the sham by knowing the
genuine first; and even passive states could not be experienced as such save by contrast with states that
are active. To the physical side, then, we naturally turn for this
knowledge which we are told is not to be found on the psychical;
and we do so the more readily as, according to the present theory,
the physical holds the primary place. But we turn in vain;
for matter is inert, and its energy only "works" by taking the
line of least resistance, like water running down hill. Moreover,
such activity as we are in search of could only be found here in
case the physical mechanism showed signs of being intelligently
directed, and that would also be evidence that psychical activity
is not illusory. Is, then, the physical side after all primary?
No, we reply: the assumption is epistemologically unsound.
This is our second objection. The order implied in the distinc-
tion of physical phenomena and psychical epiphenomena is contrary to all experience and indefensible. A physical pheno-
menon cannot have an activity or purpose of its own other-
wise it is devoid of empirical reality altogether. But objects
of perception are so far psychical; that is, they belong to im-
mediate or individual experience. Therefore we cannot regard
them as independent of this experience, nor this as their collateral
product, i.e. as epiphenomenal. Again, the phenomenality sup-
posed to be common to both involves, as we have already
seen, a fundamental identity in the standpoint of each: they
belong to the same continuous experience at different levels.
And lastly, their abstract, merely quantitative, character shows
that it is the concepts of physics, and not the facts of
immediate experience, that are symbolic, and so to say epistemic.
The attempt—either empirically or speculatively—to outflank
mind by way of matter is an absurdity on a par with getting into
a basket in the hope of being able to carry oneself.

These epistemological considerations may help us to deal with
the prime and ultimate argument for strict parallelism. When
all is said and done, it is urged, still the interaction of mind and
matter remains inconceivable. But this is hardly a sufficient
reason for denying what is prima facie a fact. Occasionals,
from Geulincx to Lotze, have acknowledged the same obscurity
in all cases of transane action. Yet they did not venture to
deny that sensations were interruptions in the psychical series,
the "occasions" for which were only to be found in the physical;
nor that purposive movements were interruptions in the physical
series, the "occasions" for which were only to be found in the
psychical. And surely such a position is more in harmony with
experience than that of the parallelists, who maintain that each
series "goes along of itself"—a statement which, as we have
repeatedly urged, contradicts psychology and assumes the physi-
cal "explanation" of life. Whereas occasionalis leaves the ques-
tion of ultimate means to be dealt with by a metaphysics
which will respect the facts, parallelism forecloses it on the basis
of a ready-made metaphysics—modern naturalism, that is to say—which psychology is indeed essentially
and entirely opposed. Staying with a dualism is as absolute as that of Descartes—but replacing his two substances by one, enjoying the oldium cum dignitate of the Unknowable—starting, too, from the physical side, no wonder such a philosophy finds that what is for us the
most familiar and of the supreme interest, the concrete world
of sense and striving, is for it the altogether inconceivable, the
supreme "world riddle." And yet if the naturalist could deign
to listen to the plainest teachings of psychology and of epistemo-
logy, the riddle would seem no longer insoluble, for his phenomenal
dualism and his agnostic monism would alike disappear.
The material mechanism which he calls Nature would rank not as the
profoundest reality there is to know: it would rather become—
what indeed "machine" primarily connotes—an instrument-
ality subservient to the "occasions" of the living world of ends;
and so regarded, it would cease to be merely calculable, and

---

1 The possibility is enough: we cannot tell what actually happens, and do not, therefore, know how far the direction of matter by mind
calls for a modification or limitation of physical hypotheses. Cf.
3 Cf. Lotze, Metaphysik, § 61 fn.
would be found intelligible as well. Psychophysical parallelism, then, we conclude, is not a philosophically tenable position; and—pursuing the metaphysical discussion as to the ultimate nature of interaction generally—we have to rest content with the second of the three possible modes of connexion above defined, as occasionalism formulates it. According to this, the two series, the psychological and the physical, are not independent and "closed" against each other; but in certain circumstances—e.g. in perception—physical changes are the occasion of psychological, and in certain circumstances—e.g. in purposive movements—psychical changes are the occasion of physical: the one change not being explicable from its psychical antecedents, nor the other from its physical.

Into the metaphysical discussion we cannot, of course, enter here. It must suffice to say that it will not be conducted on the lines of our present inquiry: it will not start from a dualism of matter and mind, either regarded as substances or as phenomena. Its problem will rather be the interaction of subject and object—a duality in the unity of experience, which by no means coincides with the dualism of matter and mind, neurosis and psychosis, and the like.

**Comparative Psychology**

48. Psychoneural parallelism is no doubt a well established generalization; nevertheless, concerning its exact range and its precise meaning there are differences of opinion. It is applicable, every one will allow, so soon as there is evidence of experiences individually acquired (cf. § 3); and from such point onwards, in ascending any biological phyllum, we find that the psychological and neural aspects differentiate and develop together. But how when we descend? Interpreting the neural correlate physiologically, and not morphologically, as referring primarily to function and not to structure, we find that even in unicellular organisms it is still present as irritability and conductivity (leading to contraction, secretion, &c.). But as at higher levels psychism is correlativo to neurosis, the principle of continuity would seem to justify us in assuming a like correspondence here. Moreover, "learning by experience," the comparative psychologist's criterion, obviously presupposes some antecedent and underlying process, of which it is the differentiation and development. And our general analysis of mind, if correct, enables us to describe this process—"the irreducible psychical minimum," of which we are here in search. We have such complete psychism—and it is the simplest we know—in the emotional or diffused movements that follow immediately upon sensation; and these are so far purposive (though not intentional) that the sensory input generally tends to heighten or retain what is pleasurable, and to alleviate or remove what is painful. Given that plasticity, which is the psychological presupposition of all acquisition, then learning by experience is a possible development from such a primitive stage.

But though every psychism has its concomitant neurosis, it is uncertain how far the converse holds good. The action of the heart, for example, depends upon nervous processes of which we have no direct consciousness. Facts of this kind have led to three hypotheses concerning the lowest forms of life, differing more or less from that just proposed. (i) Perfectibility and instinct are found, it is said, to be in inverse ratio. Hence in the lowest forms of life there is no "learning by experience," because a stationary state of complete adjustment to environment has been already attained, and all reactions have therefore become "secondarily automatic": consciousness, having served its purpose, has disappeared. To such a monistic psychophysiology it may be objected: (1) that even organic reflexes tell upon the so-called vital sense or conoesthesia, and so far—the irreducible minimum being still intact—do not preclude all possibility of learning, should occasion arise; and (2) that the psychical life, even of a Protozoan, does not, according to the best evidence, show any such mechanical finality as is here supposed. (ii) According to the second view, which is advocated by Herbert Spencer, the behaviour of the lower organisms is wholly made up of such reflexes, supposed to be devoid of all psychical concomitants; but consciousness—so far from having disappeared—first comes upon the scene at the opportune moment when the increasing complexity of the mechanism calls for its guidance. Psychologically this hypothesis is less defensible than the last, and it has already been dealt with at some length (cf. § 7). It not only assumes, as that does, far more uniformity in the interaction of organism and environment than the facts warrant, but in regarding life as prior to mind, and as the means of its evolution, it burdens science with two insoluble problems instead of one. For even if it were possible chemically to build up protoplasm, we should still be as far from organisms as a heap of bricks are from putting themselves together as a house. (iii) The last view we have to notice is essentially an extension of the preceding, and is chiefly interesting as a reductio ad absurdo of that. The physics of colloidal substances—at present wanting, but confidently expected in the near future—by certain biologists—is the key which is to unlock the mysteries of protoplasm. Certain organisms, regarded as varieties of such a substance, react positively to a given physical property of the environment, and others negatively: thus a moth flies towards the light, and a centipede runs from it—the one is positively, the other negatively, "heliotropic"; the radicle of a seed, growing downwards, is, positively, the plumule, growing upwards, is, negatively, "geotropic." Instincts are but complexes of such tropisms, and owe their character entirely to the symmetrical form and definite structure of the colloidal substance. Now if it facilitate the work of the biologist to say that when we ordinarily regard as a hungry caterpillar climbs to the tip of a branch it is forced so to do by positive heliotropism; that then positive chemiotropism sets up mastication of the young buds; and that, lastly, "we can imagine this process leading to the destruction of the substances in the skin of the animal that are sensitive to light, and upon which the heliotropism depended," so leaving it free to crawl downwards and come in contact with the new buds which have in the meantime unfolded if such language serve any useful purpose, all well and good; only it must be applied to the hungry man too: in short, all behaviour must be described in the same terms. For the champion of colloids to betake himself to consciousness as he approaches the higher forms of life is as much a breach of methodological parallelism as it is for the psychologist to fall back upon protoplasm as he approaches the lower. But to suppose that psychical processes first appear in the complicated form of association of ideas—which learning by experience is taken to imply—and at the same time to assume that such experience, even when it appears, is "ultimately due to the motions of colloidal substances," these are incongruous absurdities which only the grossest ignorance would be bold enough to maintain.

Concluding, as we have done, that mind and matter—as we provisionally call them—do really interact, we naturally infer that organic structures are not the result solely of material processes, but involve the co-operation of mental direction and selection; in other words, we are led to regard structure as partly shaped and perfected by function, rather than as functions so determined by structure, itself mechanically evolved. And such a view is justified by the fact that mechanical evolution is primarily a process of "degradation" rather than development, a case of facili descensus contrasting with the upward struggle of life per aspera ad astra. Still, the notion of life or mind as formative and directive has its difficulties. In the first place, we have no experience of mind organizing matter—no experience of the actual process, that is to say—however sure we may feel of the fact. Hence the occasionalism to which here, at any rate, science is confined. But even so, the difficulty is not wholly removed. In the handicrafts whence we derive the conception

---

3 But, of course, a thoroughgoing spiritualism ought to explain the very existence of matter as really the appearance or manifestation of mind.
PSYCHOPHYSICS—PTERIA

of organs the artificer handles, but does not literally order, his tools—as if they too were intelligent. The conscious direction of such movements is doubtless facilitated by the fact that many of the complex co-ordinations actually involved in them are carried out automatically, thanks to structural modifications, either inherited or acquired. And, regarding life phylogenetically, we can imagine this process carried back indefinitely. Indeed, if it be illogical to talk of mechanisms evolving themselves and giving rise to the beings whose ends they serve, we have no choice but to accept this dualism of mind-shaping and matter inert. No choice, that is, unless we can establish the primacy of the psychological standpoint. Here we have duality but not dualism, and the object is not inert, i.e. is not matter. But still there remain two difficulties—possibly resolvable into one—the plasticity already referred to as involved in all biological development and hereditary transmission; as to these, psychology, almost wholly in the dark.

1 Authorities.—Historical: There are few good works on the history of psychology; the only one in English, R. Blaky, History of the Philosophy of Mind from the Earliest Period to the Present Time (London, 1828), is poor. F. A. Carus's Geschichte der Psychologie (Leipzig, 1808) is at least useful for reference. A work bearing the same title by H. Siebeck (the first part consisting of two divisions— (1.) Die Psychologie von Aristoteles, (ii.) Die Psychologie von Karsten bis Wundt) is thorough and carefully done. Siebeck has also contributed a series of articles, "Zur Psychologie der Scholastiker," to the Archiv f. d. Gesch. d. Philos. (vols. i-iii). Die Philosophie in ihrer Geschichte (i. Psychologie; ii. Psychologie der neueren deutschen Psychologie) is the section dealing with the 17th-century writers prior to Kant went into a second edition in 1867; it contains a useful collection of material. From Les Origines de la psychologie contemporaine (second ed., 1901) we learn of the development of psychology in the 17th century, but a more detailed account of the 18th century would be useful, though its purpose is not primarily historical.

Positive: The recent output of systematic works on psychology has been voluminous. Among the most important of these may be mentioned B. T. Reid's The Human Mind (2 vols., 1907), W. A. Watt's Principles of Psychology (2 vols., 1890); G. F. Stout, Analytic Psychology (2 vols., 1896); A Manual of Psychology (2nd. ed., 1901); H. H. Höffding, Outlines of Psychology (1891; translated from the Danish); G. T. A. Ladd, Psychology, Descriptive and Explanatory (1894); W. Wundt, Grundriss der Psychologie (4th ed., 1901, translated); F. J. Jodl, Lehrbuch der Psychologie (2 vols., 2nd ed., 1902). Dealing mainly with experimental psychology, we have: Köpke, Grundriss der Psychologie (3rd ed., 1892), Ebbinghaus, Grundzüge der Psychologie (3rd ed., 1900), and E. B. Titchener, Experimental Psychology: a Manual of Laboratory Practice (1st ed., 1901); C. S. Myers, Experimental Psychology (1908).

On the whole, Wundt's Lehrbuch der Psychologie (2 vols., 3rd ed., 1885; edited by Cornelius) is written in the main from a Herbartian standpoint. To the honoured name of Lotze belongs a distinguished place in any enumeration of modern producing in the field of experimental psychologie (Göttingen, 1882) is still valuable. A large part of his Mikrokosmos (3 vols., 3rd ed., 1876-1880; trans. into English, 2 vols., 1889) and one book of his Metaphysik (2nd ed., 1884; also trans. into English) are, however, devoted to philosophical matters. The modern process of evolution has been as fruitful in this study as in other sciences that deal with life. In this respect Herbert Spencer's Principles of Psychology (2 vols., 3rd ed., 1881) and a collection of articles on Ethics (1879) occupy a foremost position as Spinoza's standard work. S. H. bulbs, Senses and the Intellet (4th ed., 1894) and The Emotions and the Will (3rd ed., 1872), contain a good deal of "psychological physiology," but it is a branch of the modern theory of development. Wundt's Physiologische Psychologie (3 vols., 3rd ed., 1906, 3rd ed., 1908 seq.) is indispensable to the student of this subject.

Specially interesting as treating psychological problems on new lines and by modern methods is J. H. von Uexkull's (2 vols., 1893)—perhaps the best French contribution to recent psychology. The cardinal point is the fundamental dynamical character of the psychological. R. Vierne, Kräfte der reinen Erfahrung (2 vols., 1889), supposes the individual to be a being in the Schleiermacher's treatment of psychology, to describe experience, there being no relation of the central nervous system to the environment as starting-point. His strange and far-fled terminology prevented the timely recognition of his merits; but since the author's death in 1896—a work and disappointments—quite a literature has grown up.

1 On the subject of comparative psychology generally, see Animal Behaviour (1900), by Professor C. Lloyd Morgan; L. T. Hobbese, Mind in Evolution (1901).
diverted the Persian "royal road" far to the north of its natural line. This road, in fact, followed an earlier main track whose ultimate objective had been different.

The remains of Boghaz Keui are indubitably pre-Persian and pre-Greek. The site of a large fortified city on a steep slope enclosed by two deep ravines, and falling to northward over 800 ft. from summit to base. The acropolis was strengthened with a circle of stone redoubts, between which led narrow gateways, and with internal redoubts. Just inside what seems to have been its principal entrance is a rock face inscribed with nine lines of "Hittite" characters, greatly perished (Nishan Tash), and a similar inscription, equally illegible, can be detected on a neighbouring rock. Below the acropolis, as the excavations of the B.H. C. at Boghaz Keui show, there are remains of a city so extensive as to suggest that the site has been occupied through many centuries. Both the eastern city and the western city were destroyed, and the remains of both point to a tremendous destruction, the eastern city being leveled in the 3rd millennium B.C. and the western city in the 2nd millennium B.C.

In 1906, the result of the discovery of cuneiform tablets at Boghaz Keui by E. Chante in 1890, a concession for the excavation of the site was obtained by the Berlin Oriental Society, and H. Winckler was sent to make a preliminary examination. He found a number of stone tablets in two languages, Babylonian and Hittite, and the former being that of the Arzawa letters found at Tell el-Amarna. Among them was a cuneiform copy of the treaty made by Rameses II. in his 20th year with the king of the Kheta, and inscribed on a wall at Khopet, on the wall of which the treaty was written. In 1907 Winckler returned with O. Puchstein and made a complete excavation, laying bare much of the fortifications and two temples, and finding inscribed monuments and many tablets. From these tablets, Winckler has established the fact that Boghaz Keui was the capital of a powerful Hatti dynasty from the middle of the 16th century B.C. to at least 1200 B.C. He claims further that its ancient name was Hatti. At the height of its power it ruled all Asia Minor down to the Aegean and northern Syria, with Babylon and the borderlands of the Hittites, and was rivalled in power only by the Mitanni and the Amurri (Amarnu) in Mesopotamia. It had continual relations in terms of equality with Egypt and Babylon. The four kings of the Kheta, studied by Winckler, have been identified with Boghaz Keui. The decline of Hatti power began with the expansion of Assyria after 1100 B.C. and Cappadocia seems to have been inferior to Phrygia after the rise of the Middle Assyrian dynasty in the 9th and 8th centuries B.C.

PTERIDOPHYTA (Gr. πτερός, fern, and φυτόν, plant), or generations, which together constitute the complete life-cycle of all plants higher than the Thallophyta, is perhaps the most natural characteristic of the Pteridophyta. From the germination of a spore of a fern plant, which must not be confused with the "seed" of seed-bearing plants, a small, flat, green organ develops; this is the prothallus (gametophyte, sexual generation; fig. 7). As the result of fertilization of an ovum produced by this, the fern plant (sporophyte, asexual generation) originates; from it spores are ultimately set free, with the germination of which the life-history again commences. The point common to all Pteridophyta is that from the first the gametophyte is an independent organism, while the sporophyte, though in the first stages of its development it obtains nutrition from the prothallus, becomes physiologically independent when its root develops. This independence of the two generations for the greater part of their lives distinguishes this group

the ventral canal cell and one or more canal cells. When the archegonium has opened by the separation of the terminal cells of the neck, the disintegration of the canal cells leaves a tubular passage, at the base of which is the ovum (fig. 9, b). Down this

canal the spermatozoid, which in the Ferns has been shown to be
attracted by reason of its positive irritability to malic acid, 
passes and fuses with the ovum. After fertilization the latter
surrounds itself with a cell-wall and develops into the sporophyte.
The early segmentation of the embryo differs in the several
groups, but usually the first leaf or leaves, the apex of the stem
and the first root are differentiated early, while a special
ab sor bene (the foot) maintains for some time the physio-
logical connexion between the sporophyte and the prothallus.
The sporophyte is always highly organized both as regards
form and structure. Root, stem and leaf can be distinguished
even in the simplest forms, and the plant is traversed by a well-
developed vascular system. The reproductive organs of the
sporophyte are the sporangia, within which the spores are
produced; the sporangia are often borne on in or in relation to
leaves, which may be more or less distinct from the foliage
leaves in form and structure (cf. fig. 2). The cells of the wall
of the sporangium are usually so constructed as to determine
the dehiscence of the sporangium and the liberation of its spores.
The spores produced in each sporangium vary from very many
to a single one in the case of some heterosporous forms. These
latter bear spores of two kinds, microspores and megaspores,
in separate sporangia. From the microspore an extremely
reduced male prothallus and from the megaspore the female
prothallus, develops (cf. fig. 1, e). The spores of the homosporous
Vascular Cryptograms are usually of small size; the prothallus
produced from them usually bear both antheridia and archegonia,
though under special conditions an imperfect sexual differential
may result. The complete life-history, with its regular
alternation of gametophyte and sporophyte, is now known in all
except a few rare genera of recent Pteridophyta, and will be
described in connexion with the several groups. A cytological
difference of great importance between the two generations can
only be mentioned in passing. The nuclei of the cells of the
sexual generation possess a definite number of chromosomes
and this number is also characteristic of the sexual cells. On
fertilization the number is doubled and all the cells of the spore-
bearing generation have the double number. On the formation
of the spores a reduction to the number characteristic of the
gametophyte takes place.

The systematic arrangement of the Vascular Cryptograms
for the purposes of identification and description necessarily
remains unchanged, while the comparative morphol-
ogy is being more fully worked out. But modifications
in the order of placing the natural groups are of
importance in expressing the results of such investigations.
Such a scheme may be placed here in a tabular form before
entering on the consideration of the life-history, natural
history, morphology, and classification of the several groups:—

Pteridophyta.

I. Equisetales

II. Sphenophyllales

III. Psilotales

IV. Lycopodiales

V. Ophioglossales

VI. Filicales

These main subdivisions are of unequal size and importance.
The Sphenophyllales are only known in a fossil state, while the
Equisetales, Lycopodiales and Filicales include both living and
extinct representatives. The small groups of recent plants forming
the Psilotales and Ophioglossales are given independence in this
scheme of classification owing to their exact affinities with the other
phyla being at present doubtful.

I. Equisetales.—The plants of the single living genus
Equisetum, which vary in height from a few inches to 40 ft.,
have subterranean rhizomes, from which the erect shoots arise.
The habit of the plant depends on the degree of branching rather
than upon the foliage. The internodes are elongated and
hollow. The leaves are borne in whorls on each whorl
cohering, except at their extreme tips, to form a sheath. The
leaves of successive whorls alternate with one another, and this
also applies to the branches which arise in the axil of the leaf
sheath. In most species many of these buds, which alternate
with the leaves, remain dormant, but in others the aerial shoots
are copiously and repeatedly branched. In some species
branches of the rhizome with tuberous internodes are formed,
which serve as a means of vegetative reproduction. The roots
which arise from the base of the lateral buds remain undeveloped
on the aerial stem. The vascular bundles equal in number the
leaf-teeth from which they enter the stem and form a single ring.
Each bundle runs downwards through one internode and then
divides into two branches which insert themselves on the alter-
nating bundles entering at this node. The young stems, and
the older stems of certain species, are clearly monostelic; but in
other species an inner and outer endodermis may be present,
or an endodermal layer surrounds each bundle. The vascular
bundles themselves are collateral, the xylem consisting of the
protoxylem, towards the centre of the stem, and two groups of
xylem, between which the phloem is situated; the protoxylem
elements soon break down, giving rise to the central canal.
Only the median or carinal strand of xylem is common to stem
and leaf; the lateral cauline strands possibly represent the
remains of a centripetally developed mass of primary xylem.
There is no secondary thickening except at the node in E.
maximum, where some short tracheids, arranged in radial rows,
are from a cambium. The stems, the surface of which exhibits
a number of ridges with intervening furrows, perform the greater
part of the work of assimilation. The chlorophyll-containing
tissue reaches the surface at the sides and base of the furrows,
deeply sunk in the tissue; the spermatozoids consist of a spiral of two or three coils, the numerous cilia being attached to the pointed anterior end. The female prothalli, which are sometimes branched, consist of a thick cushion bearing thin, erect lobes, at the base of which the archegonia are situated. The necks of the latter are short, the central series of cells consisting of ovum, ventral canal cell and one or two canal cells. The half of the embryo directed towards the archegonial neck gives rise to the apex of the stem and a sheath of three leaves, the other half to the small foot and the primary root. The first shoots are of limited growth, being replaced by lateral branches, which gradually acquire the number of leaf-teeth characteristic of the species.

Fossil species, some of which attained a great size, are known, to which the name *Equisetites* is given, since these are closely allied to the existing forms. Two other extinct genera, *Phyllothea* and *Schizophyllum*, may be mentioned here. Abnormal specimens of *Equisetites* in which the strobilus is interrupted by whorls of leaves are of interest for contrast. The most important and best known of the extinct Equisetales are, however, the Calamites (see Palaeobotany: *Palaeo*). In the primary structure of the stem the Calamites present many points of resemblance to *Equisetum*, but secondarily they deviated from it in both stem and root. These plants, which appear to have grown in swampy soil, thus attained the dimensions of considerable trees. The leaves, which were of simple form (except in *Archaeocalamites*, where they forked), were inserted in whorls at the nodes: they were either free from one another or cohered by their bases into a sheath. The branches alternated in position with the leaves, and sprang from just above the insertion of the latter. Some of the branches terminated in cones, which present a general similarity to those of *Sphenophyllum*. This similarity is in *Archaeocalamites*, an ancient type found in Upper Devonian rocks; in this the strobilus consists of peltate sporangiophores inserted in whorls on the axis. In the other Calamarian strobili known the whorls of sporangiophores are separated by whorls of bracts. In some the sporangiophores stood midway between the sterile whorls, while in others they approached the whorl above or below. There is a close resemblance between these sporangiophores and those of *Equisetum*, but as a rule only one sporangium was formed on each. Some of these Calamites, with their sporangiophores, sporangia, and megaspores being found in the same cone.

Our knowledge of the extinct Equisetales, full as it is with respect to certain types, does not suffice for a strictly phylogenetic classification of the group. The usual subdivision is into Equisetae (including *Equisetum* and *Equisetites*, with *Phyllothea* and *Schizophyllum* may be provisionally associated), and Calamariaceae (including *Calamites* and *Sphenophyllum*).

II. Sphenophylleaæ.—The two very distinct genera *Sphenophyllum* and *Cheirostrobus*, included in this group, are known only from the Palaeozoic rocks. Though the high specialization of this ancient group of plants renders the determination of their natural affinities difficult, indications are afforded by anatomy and the morphology of the strobilus.

In general appearance the species of *Sphenophyllum* (the remains of *Cheirostrobus* known do not allow of any idea of its habit being formed) present some resemblances to the Equisetales. The long, spiral, or often forked, stems bear on both the primary and secondary axes, a row of leaf-traces for each leaf; they are thus analogous to the xylem tracheids of *Equisetum*. The leaves, as a rule, are pinnate, and the primary veins are continued into the leaf-blades. The wood consists of three or more xylem groups; in *Cheirostrobus* they were more numerous. The anatomy of the stem is thus very unlike that characteristic of the Equisetales, and presents essential points of resemblance to the Lycopodiales and especially to the Psilotales. The general morphology of the stem, however, is often allied to that of the Calamariaceae, and suggests some affinity with the Equisetales. The cone of *Sphenophyllum* consisted of a single axis bearing at the nodes whorls of bracts, united below into a sheath. The overlapping bracts afforded protection to the sporangia, which were borne on sporangiophores springing from the upper surface of the coherent bracts near their origin from the axis; two sporangiophores usually rose from each bract, and sometimes adhered to its upper surface for some distance. Each bent round at the upper end, and bore one or two sporangia.

The fossil strobili found in the Carboniferous strata in general had a wall of a single layer of cells, which were larger towards the
base, where they continued into the epidermis of the sporangiophore. In *Sphenophyllum* fertile both the ventral lobes of the sporophyll (corresponding to the sporangiophores in other species) and the dorsal lobes, which in other species are sterile, were developed as peltate sporangiophores. In other species of *Sphenophyllum*, which are known only as impressions, single sporangiophora, or groups of four, appear to have been inserted directly on the upper surface of the bracts. In *Cheirolepis* a similar relation of sporangiophores to bracts. Each bract here each bract was divided into three segments. From each segment, near its base, a stalked peltate sporangiophore arose; this bore four sporangiophora, which hung parallel to the stalk.

That these three sterile segments, with their sporangiophores, are clearly comparable to one of the bracts of *Sphenophyllum*, with its sporangiophores, is shown by the vascular supply in each case being derived from a single leaf-trace. So far as at present known, the *Sphenophyllales* were homosporous. The differences between the two genera may be surmised above are sufficiently marked to justify the division of the *Sphenophyllales* into the two orders *Sphenophyllaceae* and *Cheirolepidae*. A consideration of the characters of both shows that the Psilotales are the nearest living representatives of the *Sphenophyllales*, while resemblance suggesting actual relationship exist between this group and the Equisetales and Lycopodiaceae. It has been suggested that the *Sphenophyllales* may have sprang from a very old stock which existed prior to the divergence of the latter groups. So long, however, as our knowledge of these phyla is confined, as at present, to specialized forms, the nature of the relationship between them must remain to some extent hypothetical.

III. PSILOTALES.—The two genera *Psilotum* and *Tmesipteris*, which are provisionally isolated in this group, have usually been classed with the Lycopodiaceae. Recent work both on their anatomy and on the morphology and structure of their sporoproducing organs has however tended to show that their peculiarities can be best understood in the light of our knowledge of the *Sphenophyllales*. Some authorities place them in this group and there is much to be said in support of the close relationship implied. The Psilotaceae, however, differ from the *Sphenophyllales* in a number of definite features, such as the arrangement of the leaves singly and not in whorls, and the mode of branching. These differences and our comparatively imperfect knowledge of the *Sphenophyllaceae* plants which most closely resemble the Psilotaceae appear to justify the provisional isolation of the latter as a distinct group, showing affinities with both the *Sphenophyllales* and Lycopodiaceae. In both *Psilotum* and *Tmesipteris* the functions of the root-system, which is completely absent, are performed by leafless rhizomes bearing abundant hairs and inhabited by an endophytic fungus. *Psilotum* lives epiphytically or in soil rich in humus, while *Tmesipteris* is epiphytic (and, it has been suggested, partially parasitic) upon stems of tree ferns: the former has small scale-like leaves; those of the latter are of considerable size. The stem is monostelic, the protoxylem groups being towards the periphery of the xylem, the development of which is thus centripetal; the centre of the stele is occupied by sclerenchymatous tissue. The leaves, which bear the sporangiophora, are dichotomous, and do not form definite cones, but alternate in irregular zones with the foliar leaves. The sporophylls may exceptionally undergo further dichotomies and bear more numerous sporangia. The sporangia of the Psilotaceae are associated in synangia, which occupy the same position relatively to the sporophyll, as the single sporangium of *Lycopodium* or the group of sporangia in *Sphenophyllum majus*. The careful study of the development of the synangium of *Tmesipteris*, which consists of two loculi, and of *Psilotum*, which consists of three, has shown that their structure can be explained as originating by the septation of a single sporangium resembling that of *Lycopodium*. Other views of the nature of the Psilotaceae synangium are, however, possible, and indeed the existence of both simple and complicated sporangiophores in the Sphenophyllaceae leaves the question open as to whether the synangium in existing Psilotaceae is a relatively simple type of sporangiophore which has persisted unaltered or is the result of reduction from a more elaborate structure. There is some reason to believe that the prothallus of *Psilotum* resembles some *Lycopodium* prothallus, but conclusive evidence is wanting; that of *Tmesipteris* is unknown.

IV. LYCOPODIACEAE.—The living representatives of this group are of small size compared with the related plants which lived in Palaeozoic times. A large proportion of the living species are tropical, though others have a wide distribution. As general characteristics of the Lycopodiaceae, the simple form of the leaves, which are generally of small size, and the situation of the sporangia on the upper surface of the sporophylls, which are generally associated in cones, close to their insertion on the axis, may be mentioned; there are both homosporous and heterosporous forms, the prothalli exhibiting corresponding differences. A number of species of *Lycopodium* are epiphytic and those of *Isoetes* live submerged in water. Vegetative reproduction is effected in various ways: by the separation of the branches of a creeping stem in some *Lycopodium*, the persistence through the winter of the apex of the shoot in *L. inundatum*, and by the formation of leafy bulbls on the aerial stem of *L. Selago* and others. A highly specialized means of vegetative reproduction is seen in the tubers of *Phylloglossum* and the embryos of some *Lycopods*. The modifications shown by the gametophyte of *Lycopodium* will be described below. All such special relations of the plant to its environment, which might be expected in the few forms of a large group which has persisted beyond the others, are less marked in the genus *Selaginella*. It would appear as if the latter was more suited to the conditions of the existing flora, and many of the specific forms within it may rather be regarded as recently evolved than as simply persistent.

Lycopodiaceae.—This order contains the two genera *Phylloglossum* and *Lycopodium*; the former has a single species, confined to Australia, Tasmania and New Zealand, while nearly one hundred species of *Lycopodium* are known. Erect and creeping terrestrial plants and

**FIG. 4.—Lycopodium clavatum.**

A, Old prothallus.
B, Prothallus bearing young sporophyte.
G, Portion of a mature plant showing the creeping habit, the adventitious roots and the specialized erect branches bearing the strobil or cone.
H, Sporophyll bearing the single sporangium on its upper surface.
J, Spore, highly magnified.

Pendulous epiphytes occur in the latter genus. The simple leaves, which are of small size and do not possess a ligule, are arranged spirally around the branched stem in the majority of the species. The roots of the erect forms often grow downwards in the cortex of the stem to reach the soil. The anatomy of *Lycopodium* presents considerable variety in detail, but the stem is always monostelic and the development of the xylem centripetal, the protoxylems being situated at the periphery of the stele; pericycle and endodermis surround the stele, and the wide cortex may be more or less
PTERIDOPHYTA

celerehymatous. The central cylinder of the root often shows a striking resemblance to that of the stem. The Lycopodiaceae are homosporous. The sporangia are formed on sporophylls of considerable size, situated on the upper surface and near the base of the sporophylls. The latter may differ from the bracts to which they are attached by the dehiscence of the sporangium, give rise to the prothallus, which is now, owing mainly to the investigations of Treub and Bruchmann, known in a number of tropical and temperate species. In this latter group of ferns the cells in the outer region of the spores, when liberated by the dehiscence of the sporangium, is uncertain. The sporophylls are arranged radially in the cones, and become slightly oblong in the megasporangium, which is borne on the axis just above the insertion of each sporophyll. Selaginella is heterosporous, the megasporangium being often found towards the base of the cone. The development of the micro- and mega- sporophylls, which are usually borne on different branches of the stem, is different. The megasporangium is a small cup-like structure, consisting of the small cell first cut off and a wall of cells enclosing two to four cellular ones from these latter the bicalcareous sporangia originate. The megasporangium becomes filled with the spores by the exine, which is the first to enclose the prominent end of the spore, where from the first the nuclei are more numerous, and later extending to the base. The surface of the sporophyll, which is exposed when the thick wall of the spore is ruptured, may produce a few rhizoids; upon it are unicellular, consisting of a short neck and the central series of ovum, ventral canal cell and canal cell, arise (fig. 1, c). After fertilization the embryo forms a short suspensor; the apex of the stem, with a leaf on each side, was the first to appear, but this later becomes the apex of the root. Thus the root of the root in Selaginella is different from what obtains in the other Vascular Cryptogams. A point of interest in this heterosporous nature is the way in which the sporangium is in the form of a megasporangium, and the spores produced before the megasporangium is derived from the sporangium.

Lepidodendraceae.—This order includes only extinct forms, the best known of which are the plants placed in the genera Lepidodendron and Lepidophloios, which are well known. The important difference in the sexual organs concerns the length of the archegoniophore; this is shortest and has only a single canal cell in L. cernuum, while in L. complanatum it is longer than in any other Lepidodendraceae. On the other hand, the megasporangia are biciliate. The embryo in L. cernuum and other species with superficial green prothalli is attached to the prothallus by a small foot, and develops first as a tuberous body (the protocorm) bearing rhizoids; this forms a number of simple leaves, and it is the apex of the shoot rises later. In the saprophytic forms the protocorm is absent, and in some of them the foot is of large size (fig. 4, B). When new individuals develop, each possessing a protocorm, the leaves arise vegetatively from the roots or young shoots, while the protocorm appears in the young sporophyte. This fact leads to the consideration of Phyllocladium, which resembles the Lycopodium cernuum in many respects; it has been spoken of as a permanently embryonic form of Lycopodium: it is in some respects the nearest existing terrestrial Pteridophyta. Its prothallus resembles that of L. cernuum, but wants the crown of assimilating lobes. The plant is reproduced by tuberous prothalli, the protocorm is bearing first a number of protospores and later the upshot with its single terminal strobilus. The sporangia are of those of Lycopodium in structure and position.

Selaginellaceae.—The single genus of this order (Selaginella) contains between three to five species, the structure of the latter is considerable diversity among them as regards external form, the majority having dorsiventral aerial shoots with ophichthous leaves. The sporangia are usually sessile, some of them are radial, the xylem is relatively small and the leaves alike. The stem consists of one, two or several stelae; in one species the stelae is tubular. In the young sporophyte the xylem, which usually develops from two protogynous groups. In the aerial stem of the British species (S. spinosa) the protogynous groups arranged round the periphery, much as in Lepidodendron. The cells of the endomesophylls are developed as trabeae. These are the spirally disposed bands of thin-walled cells, forming the air-space surrounding each stelae. The mesophyll is an obvious feature of the leaf. In some species a denticulation of the leaf encloses the ligule, regarding the function of which little is known. The roots, the stele of which is monarch, may arise directly from the stem, or be borne on rhizohypos, which spring from the shoot at the point of branching, and root on reaching the soil. In structure they resemble the roots, but their morphological nature is uncertain. The sporophylls are arranged radially in the cones, and become slightly oblong in the megasporangium, which is borne on the axis just above the insertion of each sporophyll. Selaginella is heterosporous, the megasporangium being often found towards the base of the cone. The development of the micro- and megaspores, which are usually borne on different branches of the stem, is different. The megasporangium is a small cup-like structure, consisting of the small cell first cut off and a wall of cells enclosing two to four cellular ones from these latter the bicalcareous sporangia originate. The megasporangium becomes filled with the spores by the exine, which is the first to enclose the prominent end of the spore, where from the first the nuclei are more numerous, and later extending to the base. The surface of the sporophyll, which is exposed when the thick wall of the spore is ruptured, may produce a few rhizoids; upon it are unicellular, consisting of a short neck and the central series of ovum, ventral canal cell and canal cell, arise (fig. 1, c). After fertilization the embryo forms a short suspensor; the apex of the stem, with a leaf on each side, was the first to appear, but this later becomes the apex of the root. Thus the root of the root in Selaginella is different from what obtains in the other Vascular Cryptogams. A point of interest in this heterosporous nature is the way in which the sporangium is in the form of a megasporangium, and the spores produced before the megasporangium is derived from the sporangium.

Lepidodendraceae.—This order includes only extinct forms, the best known of which are the plants placed in the genera Lepidodendron and Lepidophloios, which are well known. The important difference in the sexual organs concerns the length of the archegoniophore; this is shortest and has only a single canal cell in L. cernuum, while in L. complanatum it is longer than in any other Lepidodendraceae. On the other hand, the megasporangia are biciliate. The embryo in L. cernuum and other species with superficial green prothalli is attached to the prothallus by a small foot, and develops first as a tuberous body (the protocorm) bearing rhizoids; this forms a number of simple leaves, and it is the apex of the shoot rises later. In the saprophytic forms the protocorm is absent, and in some of them the foot is of large size (fig. 4, B). When new individuals develop, each possessing a protocorm, the leaves arise vegetatively from the roots or young shoots, while the protocorm appears in the young sporophyte. This fact leads to the consideration of Phyllocladium, which resembles the Lycopodium cernuum in many respects; it has been spoken of as a permanently embryonic form of Lycopodium: it is in some respects the nearest existing terrestrial Pteridophyta. Its prothallus resembles that of L. cernuum, but wants the crown of assimilating lobes. The plant is reproduced by tuberous prothalli, the protocorm is bearing first a number of protospores and later the upshot with its single terminal strobilus. The sporangia are of those of Lycopodium in structure and position.

Selaginellaceae.—The single genus of this order (Selaginella) contains between three to five species, the structure of the latter is considerable diversity among them as regards external form, the majority having dorsiventral aerial shoots with ophichthous leaves. The sporangia are usually sessile, some of them are radial, the xylem is relatively small and the leaves alike. The stem consists of one, two or several stelae; in one species the stelae is tubular. In the young sporophyte the xylem, which usually develops from two protogynous groups. In the aerial stem of the British species (S. spinosa) the protogynous groups arranged round the periphery, much as in Lepidodendron. The cells of the endomesophylls are developed as trabeae. These are the spirally disposed bands of thin-walled cells, forming the air-space surrounding each stelae. The mesophyll is an obvious feature of the leaf. In some species a denticulation of the leaf encloses the ligule, regarding the function of which little is known. The roots, the stele of which is monarch, may arise directly from the stem, or be borne on rhizohypos, which spring from the shoot at the point of branching, and root on reaching the soil. In structure they resemble the roots, but their morphological nature is uncertain. The sporophylls are arranged radially in the cones, and become slightly oblong in the megasporangium, which is borne on the axis just above the insertion of each sporophyll. Selaginella is heterosporous, the megasporangium being often found towards the base of the cone. The development of the micro- and megaspores, which are usually borne on different branches of the stem, is different. The megasporangium is a small cup-like structure, consisting of the small cell first cut off and a wall of cells enclosing two to four cellular ones from these latter the bicalcareous sporangia originate. The megasporangium becomes filled with the spores by the exine, which is the first to enclose the prominent end of the spore, where from the first the nuclei are more numerous, and later extending to the base. The surface of the sporophyll, which is exposed when the thick wall of the spore is ruptured, may produce a few rhizoids; upon it are unicellular, consisting of a short neck and the central series of ovum, ventral canal cell and canal cell, arise (fig. 1, c). After fertilization the embryo forms a short suspensor; the apex of the stem, with a leaf on each side, was the first to appear, but this later becomes the apex of the root. Thus the root of the root in Selaginella is different from what obtains in the other Vascular Cryptogams. A point of interest in this heterosporous nature is the way in which the sporangium is in the form of a megasporangium, and the spores produced before the megasporangium is derived from the sporangium.
The several orders of Lycopodiales described above, while presenting a number of features in common, are distinctly isolated from one another. A natural classification of such specialized plants can only be obtained when the extinct forms are more fully known. What is known at present, while it does not indicate the phylogeny of the Lycopodiales, at least shows that such living orders as Lycopodicae and Selaginellaceae cannot be regarded as forming a linear series. The difficulty is increased when it is borne in mind that the small surviving forms probably have a long geological history, and may have coexisted with the Lepidodendraeaceae. For these reasons no attempt has been made to arrange the orders in larger divisions, since such a division as that of the ligulate and elgulate forms, while convenient for practical purposes, may not express the phylogeny of the group. The Psilotaceae, formerly included in the Lycopodiales, have been described separately owing to their resemblance to the Sphenophyllaeae. It remains to be mentioned that the Isoëtaceae have been regarded as more nearly allied to the Filicales than to the former, near which they are here placed.

VI. OPHIOGLOSSALES.—The peculiarities of this small order of Pteridophyta render their systematic position a matter of doubt, especially in the absence of evidence as to their geological history, and justify their separation for the present from the other main natural groups. In the three genera, Ophioglossum, Botrychium and Helminthostachys, there is an underground rhizome, from which one leaf or few leaves with sheathing bases are produced annually; the roots arise in more or less definite relation to the insertion of the leaves. The latter are simple, or irregularly lobed in Ophioglossum, more or less compoundly pinnate in Botrychium and palmately pinnate in Helminthostachys. The fertile branch or branches are situated on the adaxial surface of the leaves, and may be simple, as in Ophioglossum (fig. 2, d), or more or less complex, the degree of branching in the sterile and fertile segments exhibiting a general parallelism. The stem is monostelic, the arrangement of the xylem and phloem being collateral. The endodermis and pericycle surround the whole stele in Botrychium and Helminthostachys; in Ophioglossum each bundle has a separate sheath. Well-marked secondary thickening occurs in Botrychium. In the roots of Ophioglossum and Botrychium and in the first formed roots of Helminthostachys an endophytic fungus is present, forming a mycorhiza—the stele in the larger roots has the usual radial arrangement of xylem and phloem; monarch roots occur in Ophioglossum. The morphology of the fertile spike is a disputed question, upon the answer to which the systematic position of the Ophioglossaceae largely rests. The spike is most simple in Ophioglossum, where it bears on each side a row of large sporangium, which hardly project from the surface, the vascular bundles occupying a central position. In the young spike, which arises when the leaf is still very small, a band of tissue derived from superficial cells is distinguishable along either side; this sporangiogenous band gives rise to the sporogenous group, the sterile septa between them, and the outer walls of the sporangium. The spike of Helminthostachys corresponds to that of Ophioglossum, but in it the sporangia are borne on two lateral rows of branched sporangiophores. The sporangia themselves resemble those of Botrychium, which project from the ultimate subdivisions of the branched spike; each is developed from a number of cells, the sporogenous tissue arising from a single cell. Two divergent views of the morphology of the fertile spike in these plants have been entertained. The older view was that it was a fertile segment of the leaf; and though its ventral position presents a difficulty, this must be regarded as a possible explanation; the occasional occurrence of sporangia on the lamina in Botrychium has been regarded as supporting it. On the other hand, the spike has been explained as due to the elaboration of a single sporangium occupying a similar position with regard to the leaf as in the Lycopodiales, and evidence of considerable weight has been brought forward in support of this interpretation. The important bearing of this question on the relationship of the Ophioglossaceae to the phyla of the Filicales and Lycopodiales will be obvious.

The position of the fertile spike in relation to the leaf corresponds to that of the symangium or sporangiophores in the Psilaceae and Sphenophyllaceae. The Ophioglossaceae are homosporous, and the prothallus, which are known in species of all three genera, are subterranean and saprophytic (fig. 1, f, g). The prothallus of O. pedunculatum, as observed by Mettenius, ascended the surface and produced green leaves; those of the other species known are wholly saprophytic, and contain an endophytic fungus. Those of Ophioglossum are cylindrical, while the dorsiventral prothallus of Botrychium bears the sexual organs on the upper surface. They resemble each other generally, but bear a resemblance to the saprophytic prothall of certain Lycopodia. Important points of difference exist, however, in the apical position of the meristem of the Ophioglossaceous prothallus, in the presence of a basal cell to the archegonium, and in the multiciliate spermatogonia. In these respects, in the megaphyllum habit and in certain anatomical features, the Ophioglossaceae approach the Filicales. Some species of Botrychium have recently been found to have embryos provided with a suspensor. The position of the Ophioglossaceae can at present only be regarded as an open question, in considering which the possible antiquity of the group must be borne in mind.

VI. FILICALES.—This group of Pteridophyta differs from the others in being well represented in our present flora by forms, many of which can be regarded not as archaic types which have persisted to the present day, but as having been evolved in comparatively recent periods. The Ferns exhibit a wide range in size from the minute epiphytic Hymenophyllaceae, with leaves barely a centimetre in length, to gigantic tree-ferns 80 ft. or more in height. A general characteristic of their habit is the large size of the leaves, which are often highly compound, relatively to the stem. Some ferns have a longer or shorter erect stem often clothed by the persistent bases of the leaves; in others the stem creeps on the surface of the substratum or is subterranean. Its surface is clothed with filamentous or scaly hairs (paleae), which protect the growing point; and adventitious roots spring from it. The position of the branches varies in the group; they are only exceptionally axillary (Hymenophylaceae, Botryopteridaceae). The anatomy of the stele in the stem exhibits on the whole a progression from a solid protostele through a tubular solenoste to one or more circles of separate steles derived by the breaking up of the solenoste. The leaf-traces usually interrupt the continuity of the stele of the axis on their departure. The sporangia are borne in groups (sori) on the under surface of the leaves; sometimes the fertile leaves differ more or less from the purely vegetative ones. The form of the sorus and the structure of the sporangium are of great systematic importance. The sorus is frequently protected by an outgrowth from the surface or margin of the leaf called the indusium. Heterospory is only known in the Hydropteridaceae. The prothallus developed from the spore is green and in most cases dorsiventral, bearing the archegonia and antheridia on the under surface. Various of the more striking adaptive modifications in the gametophyte and sporophyte, and certain effects of altered external conditions which have been ascertained experimentally, may be briefly mentioned. The dorsiventrality of the prothallus has been shown to depend mainly on the illumination, the filamentous form being retained in feeble light; a similar result is obtained when the prothallus are cultivated in water. These facts may have a bearing on the filamentous prothall of some Hymenophyllaceae. The reproduction of the prothallus by gemmae in species of Trichomanes, Vittaria and Monogramme is another interesting adaptation; the prothallus of Gymnogramme...
leptophylla is perennial, the sporophyte being annually borne on it. The phenomena of apogamy and apospory which have now been observed in a number of Ferns, may be mentioned here. In the former the prothallus produces one or more fern-plants vegetatively, the projection which develops into the sporophyte in many cases occupying the position of an archegonium. In some apogamous Ferns sporangia may occur on the prothallus and the vegetative organs of the sporophyte may also occur singly. In apospory the converse phenomenon is seen, the gametophyte springing vegetatively from the sporangium, receptacle of the sorus, or leaf-mattin of the fern-plant. In a number of cases, though not in all, apospory appears to be correlated with a failure of the sporangia to develop.

The adaptations in the vegetative organs of the sporophyte are similar to those in the Flowering Plants. Thus there are a few Ferns which climb, others are water plants, while many, especially those which live as epiphytes, are more or less xerophytic. Some of the epiphytic forms (Polypondium gercifolium, Platypodium) have strongly dismorphic leaves, the sterile leaves serving in some cases to catch falling débris, and thus to provide the plant with soil. Lastly, the symbiotic relation between the plant and ants is found in Ferns, the rhizome of Polypondium carpatorium containing cavities inhabited by these insects. The existence of these myrmecophilous Ferns suggests a possible explanation of the nectaries on the leaves of some other plants, such as the Common Bracken.

The main existing groups of the Filicaceae may now be briefly described, with special reference to the characters of gametophyte and sporophyte, which have been found of value in determining affinities.

Marattiaceae.—These are Ferns of considerable size, the large leaves of which are borne on a short, erect, swollen stem (Angiopteris, Marattiata), or arise from a more or less horizontal rhizome (Danaea, Kaufussa). The leaves, at the base of which are two large stipule-like outgrowths, have a thick leaf-stalk, and are simple or simply pinnate in Danaea, pinnate in Archangiopteris, bi- to tri-pinnate in Marattiata and Angiopteris, and digitately lobed in Kaufussa. The stem, from the ground tissue of which sclerenchyma is absent, has a complicated system of steles arranged in concentric circles; the thick roots, the central cylinders of which have several alternating groups of xylem and phloem, arise in relation to these. The pinnae, except in a few filmy forms, are thick; in Kaufussa large pores derived from stomata occur in the epidermis. The sori are borne on the under surface of the pinnae, usually in a single row on either side of the midrib, but in Kaufussa dotted over the expanded lamina. The large antheridia which arise from the marginal or submarginal rows of superficial cells, are here incompletely separated from one another and arranged in a single circle forming a synangium. The

association is closest in Danaea, where the individual sporangia of the elongated sorus, which is sunk in a depression of the leaf, open by pores; in Mayodon and Beilschmiedia (fig. 2, e) the sporangia, on the inner face; while in Angiopteris (fig. 2, f) they are almost free from one another. The spores produce a green prothallus of large size, the sexual organs of which hardly project from the surface. The cotyledon and stem grow up vertically through the prothallus, the root turning downwards into the soil.

Osmundaceae.—The two genera of this group, Osmunda and Todea, have thick erect stems, covered with the closely crowded leaf bases. The stem is monostelic, the vascular tissues being separated into curved groups comparable with collateral vascular bundles, which surround the pith. The somewhat thick roots are diarch. The leaves are large and pinnate; their lamina is usually thick, though filmy species of Todea occur. The leaf-base shows indications of stipular outgrowths. In Todea the sori, each of which consists of a single circle of bulby sporangia, are borne on the under surface of the pinnae. In Osmunda the region of the leaf which bears the sporangia has its lamina less developed; the leaf thus bears sterile and fertile pinnae, or, as in O. cinnamomea, sterile and fertile leaves may be present. The sporangia originate from single cells, though surrounding cells may contribute to the formation of the stalk. The latter is thick and short, and the wall of the sporangium, which opens by a median slit, has a group of thick-walled cells at the summit, forming the annulus. The prothallii are similar to those of the other Filicaceae, but more massive; the same may be said of the archegonia and antheridia, which, however, project more than in the preceding group.

Schizaeaceae.—The anatomy of the stem differs in the four recent genera of this order, and presents a series possibly illustrating the transition from a number of concentric steles to the intermediate step being represented by those forms in which the central cylinder is tubular. The sporangia are borne singly or in sori of two or three on the margin or under surface of leaves, the fertile pinnae of which differ more or less from the sterile segments. The sporangium is of considerable size, and dehisces by a median slit, the annulus being a more or less definitely limited horizontal ring of cells near the apex. The prothallus and sexual organs may resemble those of Polypodiaceae; in Anemia and Mehria the prothallia, though flattened, is not bilaterally symmetrical, the growing point being on one side; a filamentous type of prothallus is known in Schizaea.

Gleicheniaceae.—These forms have a horizontal rhizome, from which simply pinnate leaves arise; Platypodium, Gleichenia and Platytona have compound pinnate leaves with continued apical growth. The rhizome usually has a solid central cylinder in Gleichenia, while that of Platytona is tubular. The sporangia arise simultaneously in the sori, which are borne on the under surface of the ordinary pinnule; in those species with large sporangia the latter form a single circle, in others sporangia may also arise from the central part of the receptacle. The annulus is horizontal and the dehiscence median. The prothallus, while resembling those of the Polypodiaceae, have points of similarity with those of the preceding groups.

Matoniaceae.—This contains the single genus Matonia, two species of which are known from the eastern tropics. They are of special interest, since they have been shown to be the surviving forms of a group species which have been identified from Jurassic and Cretaceous rocks. The living species have a long rhizome, from the upper surface of which the large leaves arise; the latter are branched in a pedate manner, each branch being pinnate. The structure of the rhizome is complicated, a transverse section showing that the centre may be occupied by a solid stele, outside of which are two tubular steles. The sori are borne on the under surface of the pinnate,
each consisting of a single series of large sporangia covered by a coriaceous indusium, which is attached to the central part of the receptacle. The sporangium, which corresponds to the whole of that of the Gleicheniaceae, has a somewhat oblique annulus; the dehiscence of the sporangium is always basipetal.

Loxosomaceae.—The single genus Loxosoma has a tubular stelae in its rhizome, which bears leaves resembling those of some Davallia. The elongated receptacle of the marginal sori is surrounded by a basal annulus, which is transversely slit and is continued round the receptacle, dehiscing by a median slit, though the annulus is somewhat oblique; they have resemblances to the Gleicheniaceae. When mature, the sporangia are raised above the margin of the indusium by the elongation of the receptacle, thus facilitating the dispersion of the spores. The gametophyte is unknown.

Hymenophyllaceae.—This group, which contains the two genera *Hymenophyllum* and *Trichomanes*, is characterized by the prevalent "floral" texture of the leaves. In the two species, the sporangia develop in the racemes in which the air is constantly moist, especially in the tropics; some are terrestrial; others, some of which are very minute, are epiphytic on tree-stems. A single solid central cylinder is found in the rhizome. The sorus, which is marginal, has a long receptacle, bearing the sporangia in basipetal succession, and is surrounded by a cup-shaped indusium. The sporangia present a considerable range in size, the largest being found in species of *Hymenophyllum*, the smallest in *Trichomanes*. Each has an almost horizontal annulus, which is generally rectangular. The sporangium is cylindrical, and the gametophyte in *Hymenophyllum* is flat and variously lobed; that of *Trichomanes* may be similar, but in other species is filamentous. The archegonia and antheridia present points of similarity to those of the Blechniaceae.

Cyatheaceae.—This order includes the majority of existing tree-ferns, as well as some of smaller size. The stem has a ring of flattened stelae. The sorus has a somewhat elongated receptacle, on which the sporangia develop in basipetal succession. The indusium may be cup-shaped; it is bivalve or wanting. The dehiscence of the sporangium is almost transverse, as in the Polypodiaceae, but the annulus is usually oblique. The prothallii correspond to those of the next group.

Polypodiaceae.—This group contains the bulk of the living, and by far the larger number of the extinct, tree-ferns, includes a number of distinct lines of descent and will doubtless require subdivision as our knowledge of the morphology of the genera classed in it becomes extended. Space will not allow of an account of the subdivisions made in the recent literature. The most primitive forms have a tubular stelae (solenostele); for the most part two or more stelae, arranged in a ring (dictyostele). In a number of genera, which is reason to regard as relatively primitive, the sporangia show the same regular basipetal succession as in some of the preceding groups; in the great majority, however, the succession is not regular, but those of various ages are intermixed in the sorus (fig. 2, g). The sporangia dehice by a transverse slit, the annulus being truly vertical or, in some of the genera in which they are regularly arranged, very slightly oblique. The structure of the prothallus and sexual organs will be evident from figs. 7, 8 and 9; some of the more interesting modifications have been referred to above.

Our knowledge of the extinct Filicales cannot be readily summarized, since it is in a transition state, owing to the recent evidence which has shown that many of the fern-like plants of the Palaeozoic period belonged to a group of seed-bearing plants derived from a filicinaceous ancestry. There is, however, abundant evidence that the Ferns were represented in the most ancient floras known, though they were not such a dominant group as has hitherto been supposed. The best known of these ancient Ferns belong to the Botryopteridaceae; the characters of this group point to its having been the starting-point of several series of existing Ferns (as they have been called). The most primitive of the Filicales as arranged above will show that the several sub-orders may in general terms be said to form a series between those in which the sorus consists of a single circle of bulky sporangia and those Polypodiaceae in which the numerous small sporangia appear to be grouped without order in the sorus. When the survey is extended to the extinct Ferns of which the fructification is known, many of those from the more ancient rocks are found to group themselves with the existing sub-orders with large sporangia, such as the Marattiaceae, Gleicheniaceae and Schizaceae; the Polypodiaceae, on the other hand, do not appear until much later. The extinct forms cannot be dealt with in detail here; but it may be pointed out that their order of appearance affords a certain amount of direct evidence that the existing Ferns with a single circle of large sporangia in the sorus are relatively primitive. The series which can be constructed from a study of the sorus is in general supported by the anatomy of the sporophyte, and by the structure and sexual organs of the gametophyte. A more detailed investigation of all the characters of the Ferns will be needed before the course of evolution thus broadly indicated can be traced, but the results obtained afford a deeper insight into the general method of progression and the selective factors in the process. On the ground mainly of an examination of the sorus and sporangium, Bower has shown that the Filicales may be divided into three groups—the Simplices, Gradatae and Mixtae—in which the sporangia arise simultaneously, in basipetal succession, or irregularly in the sorus respectively. The first includes the Marattiaceae, Osmundaceae, Schizaceae, Gleicheniaceae and Matoniaceae; the second the Loxosomaceae, Hymenophyllaceae, Cyatheaceae and the Dennstaedtiaceae (a group including species placed in the *Synopsis Filicum* in *Dicksonia* and *Davallia*); while the remaining Polypodiaceae constitute the Mixtae. The change from the one type of sorus to the other may have taken place in several different lines of descent, some of which have been traced. A consideration of the biology of the sorus gives an insight into the advantages obtained by the one type over the preceding, as regards protection, spore production and the dispersal of the spores, and thus indicates the way in which natural selection may have acted. The differences in the form and mode of dehiscence of the sporangia (those of the Simplices having median dehiscence and a horizontal annulus, those of the Gradatae a more or less oblique position of the annulus and of the plane of dehiscence, while in the Mixtae the annulus is vertical and the dehiscence transverse) stand in relation to the position of the sporangia in the sorus relatively to one another. The application of the important criteria which Bower has thus pointed out to the construction of a strictly phylogenetic classification of the Filicales cannot be made until the anatomy, the sexual generation and the palaeobotanical evidence have been further examined from this point of view. Though on this account and because the subdivisions Simplices, Gradatae and Mixtae do not correspond to definite phylogenetic groups, they have not been used in classifying the Ferns above; they have great importance as an advance towards a natural classification.

Hydopteridaceae.—Two very distinct orders of heterosporous Filicales, the Salviniaceae and the Marsiliaceae, are included in this group. The difficulty of determining their exact relationship to the other orders of Ferns is increased by the more or less completely aquatic habit of the plants and the modifications and reductions in structure associated with this. The absence of an annulus from their indehiscent sporangia makes it impossible to compare them with the other Ferns in respect of this important character. It has been suggested with considerable probability that the Marsiliaceae are allied to the Schizaceae, while the Salviniaceae may possibly be related to the Hymenophyllaceae or to some other family of the Gradatae. Space will only permit of a brief general account of the more obvious features of the several genera, the structure and life-history of which are known in great detail. Unlike as they are in many respects, the two orders agree in being heterosporous. They differ in the male plant, one sporangium being produced on a reduced male prothallus bearing one or a few antheridia; these are exposed on the surface of the prothallus at the summit of the germinated megasporangium (fig. 1, d). 1.

The Salviniaceae include the two genera *Salvinia* (fig. 10) and *Asolla*. The small dorsiventral plants are in both cases floating aquatics. *Asolla* has roots depending from the lower surface of the stem into the water, while these organs are completely wanting in *Salvinia*, their place being taken functionally by highly divided fronds. The water ferns, however, the stems are always reduced, a single small leaf being produced on a reduced male prothallus bearing one or a few antheridia; these are exposed on the surface of the prothallus at the summit of the germinated megasporangium (fig. 1, d).
PTERIDOPHYTA

there is only the one terminal, functional sporangium. The microspores are united by means of hardened protoplasm into one or more mares, while the solitary megaspores have a more or less complicated episporium.

If, as has been suggested by Bower, the strobilioid types are relatively primitive, the large-leaved Pteridophyte must be supposed to have arisen early from such forms. The question cannot be discussed fully here, but enough has been said above to show that in the light of our present knowledge the main phyla of the Vascular Cryptogams cannot be placed in any serial relationship to one another.

It may even be regarded as an open question whether some of them may not have arisen independently and represent parallel lines of evolution from Bryophytic or Algal forms. This leads us to consider the question whether any indications exist as to the manner in which the Pteridophyte arose. It will be evident that no direct record of this evolution can be expected, and recourse must be had to hypotheses founded on the indirect evidence available. There appears to be no reason to doubt that the sexual generation is homologous with the thallus of a Liverwort, or of such an Alga as Coleochaete. It is with regard to the origin of the spore-bearing generation of the Pteridophyta that differences of opinion exist. This, though at first dependent on the prothallus, soon becomes independent. It may be regarded as derived from a wholly dependent sporogonium not unlike that of some of the simpler Bryophyta; the latter are assumed to have arisen from primitive Algal forms, in which, as the first step in the interpolation of the second generation in the life cycle, the fertilized ovum gave rise to a group of swarm spores, each of which developed into a new sexual plant. On this view the origin of the sporophyte is looked for in the gradual development of sterile tissue in the generation arising from the fertilized ovum, and a consequent postponement of spore-formation. Certain green Algae (e.g. Oedogonium, Coleochaete), the Bryophyta, and the simpler Pteridophyta, such as Phyllocladus, have been regarded as illustrating the method of progression, though there is no reason to regard the existing forms as constituting an actual series. For a discussion of this view, which regards the alternation of generations in Pteridophytes as antithetic and the two generations as not homologous with one another, reference may be made to the works of Celakovsky and Bower. Although the antithetic theory is supported by many facts regarding the life-history and structure of the group of plants under consideration, it is quite possible that a stage in which the sporophyte was wholly dependent on the gametophyte may never have been passed through in their evolution. The spore-bearing generation may throughout its phylogenetic history have been independent at one part of its life, and have been derived by modification of individuals homologous with those of the sexual generation, and not by the progressive sterilization of a structure which was originally devoted to asexual reproduction. A number of facts regarding the Algae, and also those relating to such deviations from the normal life cycle as apospory or apomixy, may be regarded as lending support to this view, which, in contrast to the theory of antithetic alternation, has been called that of homologous alternation. Without entering further into the discussion of these alternative theories, for which the literature of the subject must be consulted, it may be pointed out that on the latter view the strobili of Pteridophyta would not necessarily be regarded as primitive relatively to the large-leaved forms, and also that the early stages of the origin of the sporophyte in the two cases may have proceeded on different lines.

Another question of great interest, which can only be touched upon here and may hardly be the consideration of this division to the extent to which the Vascular Cryptogams are, on the one hand, intrinsically distinct forms of plants, and on the other hand, intermediates between the Ferns and the Cycads, and a number of these have been shown to bear seeds and must be classed as Pteridospermae. These forms will, however, be found discussed in the articles treating of extinct plants and the Gymnosperms, but their recognition will serve
PTEROBRANCHIA

To emphasize, in conclusion, the important position the Pteridophyta hold with regard to the existing flora.

Cultivation.—Numerous species of ferns, both temperate and tropical, are cultivated as valued ornamental plants. Species of the other groups are occasionally grown for scientific purposes in the larger botanic gardens, but their cultivation, which often presents special difficulties, need not be referred to here. While a number of ferns can be multiplied vegetatively, by buds formed on the leaves and in other ways, the regular mode of propagation is by spores shed from the ripe sporangia. The spores should be thinly sprinkled on the surface of the soil in well-drained pots, which should stand in saucers filled with water and be covered with glass plates. After the prothallii have attained some size and bear sexual organs the pots should be occasionally sunk in water so as to flood the prothallus with air and facilitate the germination of the plants developed on the prothallii should be carefully pricked out into other pans and later transferred to 3-in. pots. When the pots are fairly filled with roots the plants may be shifted into larger ones.

In most cases this can be performed with little risk, but the Gym-chenias, for example, must only be cut into large portions, as small divisions of the rhizomes are almost certain to die; in such cases, however, the points of the rhizomes can be led over and layered into small masses or sections, to which roots grow from the parent plant until they become well rooted. In potting the well-established plants, and all those of considerable size, the soil should be used in a rough tufy state, not sifted but broken, and the pots filled with broken crocks or charcoal and as much sand as will facilitate free percolation should be mixed with it.

The stave ferns require a day temperature of 65° to 75°, but do not thrive in an excessively high or close dry atmosphere. They require only such shade as will shut out the direct rays of the sun, and though an abundant moisture must be supplied, the atmosphere should not be loaded with it. The water used should always be at or near the temperature of the house in which the plants are growing. Some ferns, in the different kinds of Gymnogrammos and Cleistophyes, prefer a dryer atmosphere than others, and the former do not bear a lower winter temperature than about 60° by night. Most other stave ferns, if dormant, will bear a temperature as low as 55° by night and 70° by day from November to February. About the middle of the latter month the whole collection should be turned out of the pots and retrained or repotted into larger pots as required. This should take place before growth has commenced. Towards the end of March the night temperature may be raised to 60°, and the day temperature kept at 70° to 75°, the plants being shaded in bright weather.

Such ferns as Gymnogrammos, which have their surface covered with golden or silver powder, and certain species of scaly-surfaced Cleistophyes and Nothochlaena, as they cannot bear to have this powder disturbed, should never be syringed; but most other ferns may have a moderate sprinkling occasionally (not necessarily daily) and as the season advances sufficient air and light must be admitted.

Abth. 4; Leipzig, 1898-1902); Bower, The Origin of a Land Flora (London, 1906); Goebel, Organographie der Cryptogamen (Oxford and London, 1898); Fitch, Filicium (London, 1874); Baker, Fern Allies (London, 1887); Christ, Die Fundkäuter der Erde (Jena, 1897); Seward, Fossil Plants (Online, 1898). In those works marked with an asterisk copious references to the recent literature of the subject will be found.

PTEROBRANCHIA, a zoological group established by Ray Lankester in 1877. It contained at that time the single genus Rhabdopleura, a minute animal dredged by Sars off the Lofoten Islands, and by Norman off the Shetlands. Rhabdopleura was at first regarded as an aberrant Polyzoon, but with the publication of the Challenger Report (Cephalodiscus) in 1887, it became clear that Cephalodiscus, the second genus now included in the order, had affinities in the direction of the Enteropneusta. The connection of the Pterobranchia with the Polyzoon is in the highest degree questionable.

Rhabdopleura is no doubt of world-wide distribution, since it has been recorded in various localities from Greenland to South Australia, and use is made of it in water of the Indian and Pacific Oceans. Cephalodiscus, which for many years was known solely as the result of a single dredging by the "Challenger" from 245 fathoms in the Straits of Magellan, has recently been found in entirely different parts of the world, as for instance between Japan and Korea at 100 fathoms, at about half that depth off the south-east coast of Celebes, and between tide-marks on the coast of Borneo.

It appears to be common in the neighbourhood of Cape Town, while the recent Antarctic expeditions have shown that it occurs in various localities from the Falkland Islands to the Antarctic circle. No less than twelve species, referred to three sub-genera (Demiiothecia, Idiothecia, Orthoecus), have now been described; but it is at present uncertain whether more than a single species of Rhabdopleura is valid, although several specific names have been suggested for specimens from different localities.

Both genera are characterized by their habit of secreting a tubular gelatinoid investment, the "conoeicum," composed of a number of superposed lamellae, doubtless the result of its intermittent secretion, mainly though perhaps not exclusively, by the proboscidial parts of the zooids. In Rhabdopleura each zooid forms its own delicate tube composed of a characteristic series of distinct rings. In Cephalodiscus the coenoeicum is more massive, and may contain a continuous irregular cavity in which the zooids live (Demiiothecia), or may be secreted in such a way that each zooid has its own independent tube (Idiothecia, Orthoecus).

The zooids are a modification of the type of structure known in Balanoglossus, from which they differ principally in the following respects: (i) The alimentary canal, instead of being straight, has a U-shaped flexure, the dorsal line between the mouth and the anus being short. (ii) The proboscs (fig. 1, b), known as the "buccal shield," is a large organ, strongly flattened in an antero-posterior direction, its ventral lobe usually concealing the mouth. (iii) The collar is produced dorsally into arms (one pair in Rhabdopleura, four to eight pairs in Cephalodiscus), each of which bears numerous ciliated tentacles, the organs by which the microscopic food-particles are conveyed to the mouth. (iv) The third division of the body, the metasome, is prolonged ventrally into a relatively enormous outgrowth containing the loop of the alimentary canal, beyond which projects a stalk (fig. 1, c), of a length varying with the state of contraction and perhaps with the species. (v) The stalk gives rise to buds, by which the colonial habit is acquired. While in Rhabdopleura the buds remain in organic continuity with the parent, in Cephalodiscus they become free at an early stage, and the coenoeicum accordingly contains a number of separate individuals. In the living Cephalodiscus a zooid can crawl by means of its proboscis over the gelatinous processes of the outer side of the coenoeicum, a position which it can assume owing to the very great extensibility of the stalk, the proximal suctorial end of which remains attached to the inner surface of some part of the coenoeicum (Anderson, 1907).

In correspondence with the fundamental constitution of the zooid, each of the three segments has its own body-cavity separated from the others. The main proboscis-cavity (fig. 2, b,c) is paired, and opens to the exterior by the two proboscis pores (p.b.p.). It contains a proboscis vessel regarded by Schepetiev as a right proboscis-cavity and in any case representing the pericardium of Balanoglossus, the glomerulus of which is also probably represented. The collar-cavity (b,c) is paired, although its ventral mesentery is not complete. It extends into the arms, which originate in the bud (fig. 1) as dorsal outgrowths of the collar. The ventral and lateral parts of the anterior
margin of the collar constitute the so-called operculum (op.), a structure which not only acts as a lower lip, but must be important in separating the food-current produced by the cilia of the tentacles from the external apertures of the collar-canal and Gill-sills. The collar-canales (fig. 3, c.p.) are a pair of ovoid organs which open from the collar-cavity to the exterior, their external pores lying immediately behind the base of the operculum.

Fig. 2.—Median (sagittal) section of Cephalodiscus dodecalophus.

The metasome contains nearly the whole of the alimentary canal, in which pharynx (fig. 2, ph.), oesophagus (oes.), stomach (st.), and intestine (int.) may be distinguished. The remarkable position of the anus (a) on the dorsal side has already been alluded to.

The metasomatic cavities are divided by dorsal (fig. 3, d.mes.) and ventral mesenteries, the latter following the outer curvature of the loop of the alimentary canal. The most conspicuous blood vessel possessed by Cephalodiscus is the dorsal vessel (d.ves.). A ventral vessel occurs on the anterior side of the metasome and forms a loop extending down the entire length of the stalk, while a "heart" projects into the cavity of the pericardium, probably connected on the ventral side of the notochord with the ventral vessel, and on its dorsal side with the dorsal vessel. At their opposite ends the dorsal and ventral vessels are probably connected with one another by means of a splanchic sinus surrounding the stomach. The original specimen of C. dodecalophus contained exclusively female zooids, in which a single pair of ovaries (figs. 2, 3, ov.) lie in the metasomatic cavities, and open to the exterior dorsally by short, highly pigmented oviducts (fig. 2, ov.). In C. nigrescens and in some other species a zooid may contain a pair of ovaries, a pair of testes, or an ovary and a testis, although the males, females and hermaphrodites do not differ from one another in external characters.

The reproductive individuals have undergone an extraordinary simplification of the organs concerned with the collection and digestion of food. Thus the arms are reduced to a single pair and possess no tentacles, there is no definite operculum, and the alimentary canal is vestigial. The testes, which correspond to the position with the ovaries of a female Cephalodiscus, constitute the greater part of the animal. Associated with these males are male zooids, which usually possess no functional reproductive organs, but have other respects the structure of an ordinary female Cephalodiscus. It appears probable that there is a certain vascular connection between these and the male individuals, which thus derive their nutriment from the neuters. The reproductive organs of Rhabdopleura have been seldom observed. They resemble those of Cephalodiscus in structure and in position, except that in each sex the b.1., gonad occurs on the right c.p., side of the body only (Scheepooff, 1906).

The eggs of Cephalodiscus d. mes., Dorsal mesentery. posses a large amount of ep., yolk, and it is practically g.s., certain that there is no Dorsal mesentery. pelagic larval form. The embryo is hatched in m., early stage, but their alimentary Canal, canal, which Pharynx, morphosis has not been ph., observed. The early development appears to resemble that of the large, vacuolated species of Balanoglossus. In the bud-development, the three-segmented condition is extremely conspicuous, and a striking feature is the great relative size of the proboscis (fig. 1.). A considerable length of the alimentary canal is said to be derived from the ectoderm in the buds of both Cephalodiscus and Rhabdopleura. Scheepooff (1907) states that in the young buds of the central part of the alimentary canal is developed from cells which are not the rudiments of the mouth.

The affinity of the Pterobranchia to the Enteropneusta may be regarded as definitely established. Considering the wide differences between the two groups in the size and external characters, and in the mode of life, including the mode of feeding, it is indeed surprising that in every important organ the two groups should show a fundamental morphological identity. Their relations to Phoronides are doubtful (see Phoronidae). The question of their affinity to other divisions of the animal kingdom depends principally on the views which are held with regard to the relationships of the Enteropneusta and Phoronides respectively. The suggestion has been made by Allmann and recently upheld by Scheepooff that Rhabdopleura is related to

PTERODACTYLES—PTOLEMIES

PTERODACTYLES (Gr. for wing-fingers), an extinct order of flying reptiles, variously known as Pterosaurus (Gr. for wing-lizards) or Ornithosaurus (Gr. for bird-lizards), whose remains occur in all Mesozoic formations from the Lower Lias to the Upper Cretaceous inclusive. Their bones are of very light, though strong construction, and hollow like those of flying birds, with well-fitting articulations, quite different from those of ordinary reptiles. The head is large and remarkably bird-like in shape, while it is fixed on the neck at the same angle as in birds. The brain is small, but resembles that of birds in its general conformation. The trunk is relatively small, with few slender ribs and a keeled breastbone (sternum). The forelimbs are always a pair of wings, the fifth digit or "little" finger being enormously elongated for the support of a smooth flying membrane (seen in specimens from the lithographic stone of Bavaria). The wings are thus constructed on the same plan as those of a bat, but instead of four fingers, only one is elongated to bear the membrane. The hind-limbs are comparatively feeble, and must have been of very little use for walking.

The remains of pterodactyles are found chiefly in marine deposits, so that these reptiles must have frequented the coastlines. They probably fed partly on fish, partly on insects; but no traces of food have hitherto been observed within the fossil skeletons. The oldest satisfactorily known member of the group is Dimorphodon from the Lower Lias of Dorsetshire. The typical species has a skull about 20 centim. in length, with large teeth in front, smaller teeth behind: its tail is much elongated and slender. Equally fine skeletons of Campylognathus have been found in the Upper Lias of Würtemberg. Other long-tailed pterodactyles occur well preserved, in the Upper Jurassic (lithographic stone) of Bavaria and Würtemberg, which is so fine-grained as to show impressions of the wing-membrane. In Rhamphorhynchos there is also a rhomboidal expansion of membrane at the end of the tail. The short-tailed Pterodactylus itself, sometimes no larger than a sparrow, is also found in the same formation. It was originally described by Collini in 1784 as an unknown sea-animal, and its true nature was first determined by Cuvier in 1809, when he named it "Pterodactyl." The Pterosaurusian of the Cretaceous period, just before their extinction both in Europe and in North America, were of enormous size, and some became toothless. A pair of wings of the toothless Pteranodon from the Chalk of Kansas, now in the British Museum, measures about five and a half metres in span. Fragments of equally large pterodactyles with teeth are found in the English Chalk.

See H. G. Seeley, The Ornithosaurus (Cambridge, 1870) and Dragons of the Air (London, 1901); S. W. Williston, paper in Kansas University Quarterly (1897), vi. 35; G. F. Eaton, papers in Amer. Journ. Science (1903-1904), 4th series, vols. xvi., xvii. (A. S. Wo.)

PTERON (Gr. πτερόν, a wing), an architectural term used by Pliny for the peristyyle of the tomb of Mausolus, which was raised on a lofty podium, and so differed from an ordinary peristyyle raised only on a stylobate, as in Greek temples, or on a low podium, as in Roman temples.

PTOLEMAEOUS, of Alexandria, surnamed Chennus, Greek grammarian during the reigns of Trajan and Hadrian. According to Suidas, he was the author of an historical drama called Sphinx, of an epic, Anhomoeus, in 24 books (both lost) and a Strange History. The last is probably satisfactorily identical with the work of which an abridgment has been preserved in Photius (cod. 190). It contains a medley of all sorts of legends and fables belonging to both the mythological and historical periods. It is probable that Chennus was also the author of a lost treatise on the life and works of Aristotle, ascribed to "Ptolemaeus" in an Arab list of his works, taken from a Syriac version of the Greek original (A. Baumstark, Aristotles bei den Syrern vom v. Jahrh. (1869; Leipzig, 1900). See editions of Photius' abridgment by J. Rouleau (1854); and A. Westermann, Mythographi graeci (1843); R. Hercher, Uber die Geschichtskdichter des Altertums (Leipzig, 1856); J. E. Sandys, Hist. of Classical Scholarship (2nd ed., 1906).

PTOLEMIES, a dynasty of Macedonian kings who ruled in Egypt from 332 to 30 B.C.

The founder, Ptolemy (Ptolemaios), son of Lagus, a Macedonian nobleman of Eordaeas, was one of Alexander the Great's most trusted generals, and among the seven "body-guards" attached to his person. He plays a principal part in the later campaigns of Alexander in Afghanistan and India. At the Susa marriage festival in 324 Alexander caused him to marry the Persian princess Artacama; but there is no further mention of this Asiatic bride in the history of Ptolemy. When Alexander died in 323 the resettlement of the empire at Babylon is said to have been made at Ptolemy's instigation. At any rate he was now appointed satrap of Egypt under the nominal kings Philip Arrhidaeus and the young Alexander. He at once took a high hand in the province by killing Cleomenes, the financial controller appointed by Alexander the Great; he also subjugated Cyrenaica. He contrived to get possession of Alexander's body which was to be interred with great pomp by the imperial government and placed it temporarily in Memphis. This act led to an open rupture between Ptolemy and the imperial regent Perdiccas. But Perdiccas perished in the attempt to invade Egypt (121). In the long wars between the different Macedonian chiefs which followed, Ptolemy's first object is to hold his position in Egypt securely, and secondly to possess the Cyrenaican, Cyprus and Palestine (Coele-Syria). His first occupation of Palestine was in 318, and he established at the same time a protectorate over the petty kings of Cyprus. When Antigonus, master of Asia in 315, showed dangerous ambitions, Ptolemy joined the coalition against him, and, on the outbreak of war, evacuated Palestine. In Cyprus he fought the partisans of Antigonus and reconquered the island (313). A revolt of Cyrene was crushed in the same year. In 312 Ptolemy, with Seleucus, the fugitive satrap of Babylonia, invaded Palestine and beat Demetrius, the son of Antigonus, in the great battle of Gaza. Again he occupied Palestine, and again a few months later, after Demetrius had won a battle over his general and Antigonus entered Syria in force, he evacuated it. In 311 a peace was concluded between the embattled parties, after which the surviving king Alexander was murdered in Macedonia, leaving the satrap of Egypt absolutely his own master. The peace did not last long, and in 309 Ptolemy commanded a fleet in person which detached the coast towns of Lycia and Caria from Antigonus and crossed to Greece, where Ptolemy took possession of Corinth, Sicyon and Megara (308). In 306 a great fleet under Demetrius attacked Cyprus, and Ptolemy's brother, Menelaus, was defeated and captured in the decisive battle of Salamis. The complete loss of Cyprus followed. Antigonus and Demetrius
now assumed the title of kings; Ptolemy, as well as Cassander, Lysimachus and Seleucus, answered this challenge by doing the same. In the winter (306–5) Antigonus tried to follow up the victory of Cyprus by invading Egypt, but here Ptolemy was strong, and held the frontier successfully against him. Ptolemy led no further expedition against Antigonus overseas. To the Rhodians, besieged by Demetrius (305–4), he sent such help as won him divine honours in Rhodes and the surname of Soûros ("saviour"). When the coalition was renewed against Antigonus in 302, Ptolemy joined it, and invaded Palestine a third time, whilst Antigonus was engaged with Lysimachus in Asia Minor. On a report that Antigonus had won a decisive victory, for a third time he evacuated the country. But when news came that Antigonus had been defeated and slain at Ipsus (301) by Lysimachus and Seleucus, Ptolemy occupied Palestine for the fourth time. The other members of the coalition had assigned Palestine to Seleucus after what they regarded as Ptolemy's desertion, and for the next hundred years the question of its ownership becomes the standing ground of enmity between the Seleucid and Ptolemaic dynasties. Henceforth, Ptolemy seems to have mingled as little as possible in the business of Asia Minor and Greece; his possessions in Greece he did not retain, but Cyprus he reconquered in 295–4. Cyrene, after a series of rebellions, was finally subjugated about 300 and placed under his stepson Magas (Beloch, Griech. Gesch. III. [ii.], p. 134 seq.). In 285 he abdicated in favour of one of his younger sons by Berenice (q.v.), who bore his father's name of Ptolemy; his eldest (legitimate) son, Ptolemy Ceraunus, whose mother, Eurydice, the daughter of Antipater, had been repudiated, fled to the court of Lysimachus. Ptolemy I. Soter died in 283 at the age of 84. Shrewd and cautious, he had a compact and well-ordered realm to show at the end of fifty years of wars. His name for bonhomie and liberality attached the floating soldier-class of Macedonians and Greeks to his service. Nor did he neglect conciliation of the natives. He was a ready patron of letters, and the great library, which was Alexandria's glory, owed to him its inception. He wrote himself a history of Alexander's campaigns, distinguished by its straightforward honesty and sobriety.

Ptolemy II. Philadelphus (309–246), was of a delicate constitution, no Macedonian warrior-chief of the old style. His brother Ptolemy Ceraunus found compensation for becoming king in Macedonia in 281, and perished in the Gallic invasion of 280–79 (see Brennus). Ptolemy II. maintained a splendid court in Alexandria. Not that Egypt held aloof from wars. Magas of Cyrene opened war on his half-brother (274), and Antiochus I., the son of Seleucus, desiring Palestine, attacked soon after. Two or three years of war left Egypt the dominant naval power of the eastern Mediterranean; the Ptolemaic sphere of power extended over the Cyclades to Samothrace, and the harbours and coast towns of Cilicia Trachea ("Rough Cilicia"), Pamphylia, Lycia and Caria were largely in Ptolemy's hands (Theoc. Idyll. xvi. 86 seq.). The victory won by Antigonus, king of Macedon, over his fleet at Cos (between 256–56; see Beloch, II. [ii.], p. 348 seq.) did not long interrupt his command of the Aegean. In a second war with the Seleucid kingdom, under Antiochus II. (after 260), Ptolemy sustained losses on the sea-board of Asia Minor and agreed to a peace by which Antiochus married his daughter Berenice (250?). Ptolemy's first wife, Arsinoë I., daughter of Lysimachus, was the mother of his legitimate children. After her repudiation he married, probably for political reasons, his full-sister Arsinoë II., the widow of Lysimachus, by an Egyptian custom abhorrent to Greek morality. The material and literary splendour of the Alexandrian court was at its height under Ptolemy II. Pompas and gay religions flourished. Ptolemy deified his parents as the thol. Ælekdol, and his sister-wife, after her death (270), as Philadelphus. This surname was used in later generations to distinguish Ptolemy II. himself, but properly it belongs to Arsinoë only, not to the king. Callimachus, made keeper of the library, Theocritus, and a host of lesser poets, glorified the Ptolemaic family. Ptolemy himself was eager to increase the library and to patronize scientific research. He had the strange beasts of far-off lands sent to Alexandria. But, an enthusiast for Hellenic culture, he seems to have shown but little interest in the native religion. The tradition which connects the Septuagint translation of the Old Testament into Greek with his name is not historical. Ptolemy had many brilliant mistresses, and his court, magnificent and dissolve, intellectual and artificial, has been justly compared with the Versailles of Louis XIV.

Ptolemy III. Euergetes I. (reigned 246–221), son of Ptolemy II. and Arsinoë I. At the beginning of his reign he reunited the Cyrenaica to Egypt by marrying Berenice the daughter and successor of Magas (who had died about 250). At the same time he was obliged to open war on the Seleucid kingdom, where Antiochus II. was dead and his sister Berenice had been murdered, together with her infant son, by Antiochus's former wife, Laodice, who claimed the kingdom for her son Seleucus II. Ptolemy marched triumphantly into the heart of the Seleucid realm, as far at any rate as Babylonia, and received the formal submission of the provinces of Iran, while his fleets in the Aegean recovered what his father had lost upon the seaboard, and made fresh conquests. This made the zenith of the Ptolemaic power. After Ptolemy returned home, indeed, Seleucus regained northern Syria and the eastern provinces, but the naval predominance of Egypt in the Aegean remained, although there are traces of its being replaced locally, towards the end of Euergetes' reign, by that of Macedonia—in Amorgos, Naxos, Syros, Nisyros, Cos and parts of Crete (see Beloch, III. [ii.], p. 463). After his final peace with Seleucus, Ptolemy no longer engaged actively in war, although his forces might occasionally mingle in the broils of Asia Minor, and he supported the enemies of Macedonia in Greece. It seems probable that his internal policy differed from his father's in patronizing the native religion more liberally; he has left larger traces at any rate among the monuments that are known to-day.

Ptolemy IV. Philopator (reigned 221–204), son of the preceding, was a wretched debauchee under whom the decline of the Ptolemaic kingdom began. His reign was inaugurated by the murder of his mother, and he was always under the dominion of favourites, male and female, who indulged his vices and conducted the government as they pleased. Self-interest led his ministers to make serious preparations to meet the threats of Antiochus III. (the Great) on Palestine, and the great Egyptian victory of Raphia (217), at which Ptolemy himself was present, secured the province till the next reign. The arming of Egyptians in this campaign had a disturbing effect upon the native population of Egypt, so that rebellions were continuous for the next thirty years. Philopator was devoted to orgiastic forms of religion and literary dilettantism. He built a temple to Homer and composed a tragedy, to which his vile favourite Agathocles added a commentary. He married (about 215) his sister Arsinoë III., but continued to be ruled by his mistress Agathocles, sister of Agathocles.

Ptolemy V. Epiphanes reigned 204–181, son of Philopator and Arsinoë, was not more than five years old when he came to the throne, and under a series of regents the kingdom was paralysed. Antiochus III. and Philip V. of Macedonia made a compact to divide the Ptolemaic possessions overseas. Philip seized several islands and places in Caria and Thrace, whilst the battle of Panormos (198) definitely transferred Palestine from the Ptolemies to the Seleucids. Antiochus after this concluded peace, giving his own daughter Cleopatra to Epiphanes to wife (193–192). Nevertheless, when war broke out between Antiochus and Rome Egypt ranged itself with the latter power. Epiphanes in manhood was chiefly remarkable as a passionate sportsman; he excelled in athletic exercises and the chase. Great cruelty and perfidy were displayed in the suppression of the native rebellion, and some accounts represent him as personally tyrannical.

The elder of his two sons, Ptolemy VI. Philometor (181–145), succeeded as an infant under the regency of his mother Cleopatra. Her death was followed by a rupture between the Ptolemaic and Seleucid courts, on the old question of Palestine.
Antiochus IV. Epiphanes invaded Egypt (170) and captured Philometor.

The Alexandrians then put his younger brother Ptolemy VII. Euergetes II., (afterwards nicknamed Physkon, on account of his bloated appearance) upon the throne. Antiochus professed to support Philometor, but, when he withdrew, the brothers agreed to be joint-kings with their sister Cleopatra as queen and wife of Philometor. Antiochus again invaded Egypt (168), but was compelled by the Roman intervention to retire. The double kingship led to quarrels between the two brothers in which fresh appeals were continually made to Rome. In 163 the Cyrenaica was assigned under Roman arbitration to Euergetes as a separate kingdom. As he coveted Cyprus as well, the feud still went on, Rome continuing to interfere diplomatically but not effectively. In 154 Euergetes invaded Cyprus but was defeated and captured by Philometor. He found his brother, however, willing to pardon and was allowed to return as king to Cyrene. In 152 Philometor joined the coalition against the Seleucid king Demetrius I. and was the main agent in its destruction. The protégé of the coalition, Alexander Balas, married Philometor's daughter Cleopatra (Thea), and reigned in Syria in practical subservience to him. But in 147 Philometor broke with him and transferred his support, together with his father, and of Cleopatra and Demetrius I., to the son of Demetrius I. He himself at Antioch was entreated by the people to assume the Seleucid diadem, but he declined and installed Demetrius as king. In 145 in the battle on the Oenoparas near Antioch, in which Alexander Balas was finally defeated, Philometor received a mortal wound. Philometor was perhaps the best of the Ptolemies. Kindly and reasonable, his good nature seems sometimes to have verged on indolence, but he at any rate took personal part, and that bravely and successfully, in war.

Philometor's infant son, Ptolemy Philopator Neos (?), was proclaimed king in Carcharia under the regency of his mother Cleopatra. Euergetes however, swooping from Cyrene, seized the throne and married Cleopatra, making away with his nephew. He has left an odious picture of himself in the historians—a man untouched by benefits or natural affection, delighting in deeds of blood, his body as loathsome in its blown corpulence as his soul. Something must be allowed for the rhetorical habit of our authorities, but that Euergetes was ready enough to shed blood when policy required seems true. He soon found a more agreeable wife than Cleopatra in her daughter by Ptolemy and Cleopatra, the future Cleopatra II., whom he nicknamed Auletes, the flute-player (85–51), setting his brother as king in Cyprus. The rights of these kings were doubtful, not only because of their illegitimate birth, but because it was claimed in Rome that Alexander II. had bequeathed his kingdom to the Roman people. Two Seleucid princes, children of Soter's sister Selene, appeared in Rome in 73 to urge their claim to the Ptolemaic throne. Ptolemy Auletes was thus obliged to spend his reign in buying the support of the men in power in Rome. Cyprus was annexed by Rome in 58, its king committing suicide. From 58 to 55 Auletes was in exile, driven out by popular hatred, and worked by bribery and murder in Rome to get himself restored to Roman power. His daughter Berenice meanwhile reigned in Carcharia, a husband being found for her in the Pontic prince Archelaus. In 55 Auletes was restored by the proconsul of Syria, Aulus Gabinius. He killed Berenice and, dying in 51, bequeathed the kingdom to his eldest son, aged ten years, who was to take as wife his sister Cleopatra, aged seventeen. In the reign of Ptolemy XII. Philopator (51–47) and Cleopatra Philopator, Egyptian history coalesces with the general history of the Roman world, owing to the war with Ptolemy and the conflict of Seleucid and Ptolemaic claims. The war of Julius Caesar (49–47). In that war the young king was killed and a still younger brother, Ptolemy XIII. Philopator, was associated with Cleopatra till 44, when he died, probably by Cleopatra's contriving. From then till her death in 30, her son, born in 47, and asserted by Cleopatra to be the child of Julius Caesar, was associated officially with her as Ptolemy XIV. Philopator Philopator Caesar; he was known popularly as Caesarion. (For the incidents of Cleopatra's reign see Cleopatra, Arsinoë.) After her death in 30 and Caesarion's murder Egypt was made a Roman province. Cleopatra's daughter by Antony (Cleopatra Selene) was married in 25 to Juba II. of Mauretania. Their son Ptolemy, who succeeded his father (A.D. 23–40), left no issue.

See Mahaffy, The Empire of the Ptolemies (1895) and Egypt under the Ptolemaic Dynasty (1896); Strack, Die Dynastie der Ptolemaer (1897); Bouche-Leclercq, Histoire des Lagides (1904, 1907); Meyer, Das Herrschehen der Ptolemaer und Römer (Leipzig, 1900).

Ptolemy (Claudius Ptolemaeus), the celebrated mathematician, astronomer and geographer, was a native of Egypt, but there is an uncertainty as to the place of his birth. Some ancient manuscripts of his works describe him as of Pelusium, but Theodorus Meliteniota, a Greek writer on astronomy of the 2nd century A.D., describes him as of Rhodes. The Ptolemies were not in antiquity distinguished by the ordinal numbers affixed to their names by modern scholars and represented according to the usual convention by Roman figures. This is merely done for our convenience. In the case of the later Ptolemies different systems of notation prevail according as the problematic Eupator and Philopator Neos are reckoned in or not.
The 12th century, says that he was born at Ptolemais Hermiou, a
Greek city of the Thebaid. It is certain that he observed at
Alexandria during the reigns of Hadrian and Antoninus Pius, and
that he survived Antoninus. Olympiodorus, a philosopher of the
Neoplatonic school who lived in the reign of the emperor
Justinian, relates in his scholia on the Phaedo of Plato that
Ptolemy devoted his life to astronomy and lived for forty years in
the so-called Πτερόν του Καμψού, probably elevated terraces of
the temple of Serapis at Canopus near Alexandria, where they
raised pillars with the results of his astronomical discoveries
engraved upon them. This statement is probably correct; we
have indeed the direct evidence of Ptolemy himself that he made
astronomical observations during a long series of years; his first
recorded observation was made in the eleventh year of Hadri-
nian, 92 A.D., and his last in the fourteenth year of Antoninus,
151 A.D. Ptolemy, moreover, says, “We make our observations
in the parallel of Alexandria.” St Isidore of Seville asserts that
he was of the royal race of the Ptolemies, and even calls him king
of Alexandria; this assertion has been followed by others, but
there is no ground for their opinion. Indeed Fabricius shows
by numerous instances that the name Ptolemy was common in
Egypt. Weider, from whom this is taken, also tells us that
according to Arabian tradition Ptolemy lived to the age of
seventy-eight years; from the same source some of his personal
appraisals have been handed down, which is generally considered
as not trustworthy, but which may be seen in Weider, Historia
astronomica, p. 177, or in the preface to Halma’s edition of the
Almagest, p. 61.

Mathematics.

Ptolemy’s work as a geographer is discussed below, and an
account of the discoveries in astronomy of Hipparchus and
Ptolemy is given in the article Astronomy: Hipparchus.

Hipparchus’ contributions to trigonometry, plane and spheric-
al, are well known. In this section we shall discuss the develop-
ment of these concepts, which is fundamentally important in the
history of mathematics.

Hipparchus of Nicaea was a Greek astronomer who lived in the
second century B.C. He is credited with the invention of trigonomet-
try, the study of the relationships between the sides and angles
of triangles. He is also known for his work on the calculation of
the lengths of the arcs of the major planets, which were used to
calculate the positions of celestial objects. Hipparchus is credited
with being the first to use the technique of triangulation to
calculate distances in astronomy.

Hipparchus’ work in trigonometry was based on the idea of
using right triangles to represent celestial objects. He used
right triangles to determine the angular distances between
planets and stars. Hipparchus’ work in trigonometry was
fundamental to the development of astronomy and
mathematics.

chords of these arcs in parts of which the diameter contains 120, the subdivisions being sexagesimal; and in the third he has inserted the thirteenth parts of the differences of these chords for each half-degree, in order that the chords of the intermediate arcs, which do not appear anywhere in the preceding book, may be by the same token known. It is an assumption that the increment of the chords of arcs within the table for each interval of 30° is proportional to the increment of the arc.

Trigonometry, we have seen, was created by Hipparchus for the use of astronomers, and since the Ptolemaic system, which is applicable to astronomy, it is not surprising that its development was prior to that of plane trigonometry. It is the subject-matter of the eleventh chapter of the *Almagest*, whilst the solution of plane triangles is not treated of until chapter xii.

To illustrate how well the Greeks supposed it to be in a circle; they must therefore have known the theorem—which is the basis of this branch of trigonometry: The sides of a triangle are proportional to the chords of the double arcs which measure the sides, and conversely. Since this is a general case of the triangle theorem, together with Eucl. I. 32 and 47, gives the complete solution. Other triangles were resolved into right-angled triangles by drawing the perpendicular from a vertex on the opposite side. In one place (Alm. vi. ch. 7; 1. 422, ed. Halma) a triangle solves a triangle in which the three sides are given by finding the segments of a side made by the perpendicular on it from the opposite vertex. It should be noticed also that the eleventh chapter of the *Almagest* is divided into the two parts or problems in plane trigonometry. The problems which are met with correspond to the following: Divide a given arc into two parts so that the chords of the doubles of those arcs shall have a given ratio; the solution is given for external section. Ultimately in this chapter, it is again mentioned that Ptolemy (Alm. vi. ch. 7; 1. 421, ed. Halma) takes 3° 8' 30", i.e. \( \frac{8}{60} \times \frac{30}{3600} \text{, as the value of the ratio of the circumference to the diameter of a circle, and adds that, as had been shown by Archimedes, it lies between 31 and 31} \frac{1}{2} \text{.}

Theoretical calculations are laid in chapter xi. on a few simple and useful lemmas. The starting-point is the well-known theorem of plane geometry concerning the segments of the sides of a triangle made by a transversal: The segments of any side of a triangle are proportional to the segments of the other two sides. This theorem, as well as that concerning the inscribed quadrilateral, was called after Ptolemy—naturally, indeed, since no reference to its source occurs in the *Almagest*. This error was corrected by Mersenne, who showed that it was known to Menelaus, and who was a supposed and geometer who lived in the reign of the emperor Trajan. The theorem now bears the name of Menelaus, though most probably it came down from Hipparchus; Chasles, indeed, thinks that Hipparchus deduced the property of the spherical triangle from that of the plane triangle, but throws the origin of the latter farther back and attributes it to Euclid, suggesting that it was given in his *Porisms*. 2 Cannot made this theorem the basis of his theory of transversals in his essay on that subject. It should be noted, however, that the theorem is not derived in the manner stated above; Ptolemy considers two cases only of the theorem, and in his commentary on the *Almagest*, he has added a two cases. The proofs, however, are general. Ptolemy then lays down the law that if the lengths of the sides of a triangle is any ratio and a diameter be drawn through the point of section, the diameter will cut the arc into two parts the chord of whose doubles are in the same ratio as the segments of the chord; and a similar theorem in the case when the chord is cut externally in any ratio. By means of these two lemmas Ptolemy deduces in an ingenious manner—easy to follow, but difficult to discover—from the theorem of Menelaus for a plane triangle the corresponding theorem for a spherical triangle: If the sides of a spherical triangle be arcs of a great circle, the chords of the doubles of the segments of any one side will be to each other in a ratio compounded of the ratios of the chords of the doubles of the segments of the other two sides. Hence, the theorem of Menelaus is now extended to one case considered, corresponding to the two cases given in plano. Theon has added two cases. The proofs are general. By means of this theorem four of Napier’s formulæ for the solution of right-angled spherical triangles were easily obtained. Ptolemy does not mention them, but in each case when required applies the theorem of Menelaus for spheres directly. This greatly increases the length of his demonstrations, which the modern reader finds still more curious, inasmuch as it was not necessary to express the relation in terms of chords—the equivalents of cosines and tangents being of later invention.

Such, then, was the trigonometry of the Greeks. Mathematics, indeed, has ever been, as it were, the handmaid of astronomy, and many important methods of the former arose from the needs of the latter. Moreover, by the foundation of trigonometry, astronomy attained its final general constitution, which called into the place of dioptrics, of which Ptolemy had been at an earlier period substituted for mechanical apparatus in solving the ordinary problems. Further, we find in the application of trigonometry to astronomy frequent examples and even a systematic use of the method of approximations—the basis, in fact, of all application of mathematics to practical questions. There was a disinclination on the part of the Greek geometers to be satisfied with a mere approximation, were it ever so close; and the unscientific agrimensior shirked the labour involved in acquiring the knowledge which was indispensable for learning trigonometrical calculations. Thus the development of the calculus of approximations fell to the lot of the astronomer, who was both scientific and practical.

We now proceed to notice briefly the contents of the *Almagest*. It is divided into thirteen books. The first book, which may be regarded as an introductory to the rest, contains the proposition that the equinoctial hours are equal in all places of the inhabited parts of the earth; that he will point out the differences of climates; that he will pass on to the consideration of the motion of the sun and moon, without which one cannot have a correct idea of the size of the earth, how it is determined by the position of the fixed stars and then the theory of the five stars called "planets." All these things—i.e. the phenomena of the heavenly bodies— he says will endeavour to explain in taking for principle that which is evident, real and certain, in resting everywhere on the surest observations and applying geometrical methods. He then enters on a summary exposition of the general principles on which his *Synthesis* is based, and addsuce arguments to show that the heavens are of a spherical form and that it moves after the manner of a sphere, that the earth also is of a form which is sensibly spherical, that the earth is in the centre of the heavens, that it is but a point in comparison with the distances of the stars, and that it has not any motion of translation. With respect to the positions of the heavenly bodies, it is a matter of observation, and he says that this supposition renders the explanation of the phenomena of the heavens much more simple, yet regards it as altogether ridiculous. Lastly, he lays down that there are two principal and different motions in the heavens; one of which all the stars are carried from east to west uniformly about the poles of the equator; the other, which is peculiar to some of the stars, is in a contrary direction to the former motion and takes place round different circles, which are nearer than the ecliptic. Ptolemy, while admitting that this supposition renders the explanation of the phenomena of the heavens much more simple, yet regards it as altogether ridiculous. Lastly, he lays down that there are two

---

1. Iler has examined the degree of accuracy of the numbers in these tables and finds that they are correct to five places of decimals.

degrees of obliquity of the sphere; hence he finds the height of the pole and reciprocally. From the same data he shows how to find at what places and times the sun becomes vertical and how to calculate the ratio of gnomons to their equinoctial and solstitial shadow. Hipparhus gives other methods; one is for use in a whole number, whereas at Alexandria he believed it to be 3° 58'; the second is that Hipparchus had made at Rhodes many observations; the third is that the climate of Rhodes holds the mean place of the sun's annual motion. Each of these methods was a little, the latter method is wanting in precision. All these matters he considers fully and works out in detail for the parallel of Rhodes.

Theon gives us three reasons for the selection of that parallel by Ptolemy. First, he thinks that the latitude of Rhodes, which Ptolemy calls the hestia, differs from the mean of the Greeks to take in hand hypothesis of this kind, 9 that he was in fact the first Greek astronomer who proposed a geometrical hypothesis for explaining the periodic motions of the planets—the famous system of epicycles and eccentrics. The second reason is a fourth reason, which he thinks is the true one, that Ptolemy had taken his examples from the works of Hipparchus, who observed at Rhodes and had made these calculations for the place where he lived. In the third place, he says it is easier to calculate the properties of each parallel, commencing with the equator, which he considers as the southern limit of the habitable quarter of the earth. For each parallel or climate, which is determined by the length of the longest day, he gives the latitude, a principal place on the parallel, and the lengths of the shadows of the gnomon at the solstices and equinox. In the next chapter he enters into particulars and inquires what are the arcs of the equator which cross the horizon at the same time as given arcs of the ecliptic, or, which comes to the same thing, the time which a given arc of the ecliptic takes to cross the horizon of a given place. He arrives at a formula for calculating ascensional influence, and tables of values assigned are changed to all of longitude for the different climates from the equator to the parallel. This chapter begins at 50°, and, of the angles of the equator and the point of origin of the ecliptic, in the following chapters of this book he determines the angles formed by the intersections of the ecliptic—first with the meridian, then with the horizon, and lastly with the vertical. This and concludes by giving tables of the angles and arcs formed by the intersection of the circles, for the solstices, for the parallel of Merœ (thirteen hours) to that of the north of the Borysthenes (24° 10'), and latitude, and by the vertical. In the night and day is seventeen hours. He then shows the use of these tables in the investigation of the length of the day for a given climate, of the manner of reducing terrestrial ellipses to the eccentric and vice versa, and of the apparent equinox and the point of origin of the ecliptic. In the following chapters of this book he determines the angles formed by the intersections of the ecliptic—first with the meridian, then with the horizon, and lastly with the vertical. This and concludes by giving tables of the angles and arcs formed by the intersection of the circles, for the solstices, for the parallel of Merœ (thirteen hours) to that of the north of the Borysthenes (24° 10').

Ptolemy says one should read the books of the ancients, and especially those of Hipparchus, whom he praises as a lover of labour and a hour of these tables, he adds, should be completely. To this the situation of the chief towns in all countries according to their latitudes and longitudes; this he promises to do in a separate treatise and has in fact done in his Geography.

But in the second chapter there are some general remarks to which attention should be directed. We find the principle laid down that for the explanation of phenomena one should adopt the simplest hypothesis that it is possible to establish, provided that it is not contradicted by the observations. This is of the most important respect. 3 This fine principle, which is of universal application, may, we think—regard being paid to its place in the Almagest—he justly attributed to Hipparchus. It is the first law of the ancients, and the word is found in the works of Theon, 4 and Plutarch, 5 and other authorities. This principle is a general principle, or rather practical injunction, that in investigations founded on observations where great delicacy is required we should select those made at considerable intervals of time in order that the result may be greater than the accuracy of observation. In all observations, even in those made with the greatest care, may be lessened by being distributed over a large number of years. In the same chapter we find also the principle laid down that the object of the calendar is not to make the mean solar time coincide with the mean lunation, and that the former is to be regulated by uniform and circular motions. This principle is stated by Ptolemy in the manner which is unfortunately too common with him—that is to say, he does not give the least indication whence he derives the great accuracy of the results arrived at. However, the word of the ancients that Plato is said to have proposed the following:

1.

of constructing a celestial globe; it also treats of the configuration of the stars, first with regard to the sun, moon, and planets, and then with regard to the horizon, and likewise of the different aspects of the stars and of their rising, culmination and setting simultaneously with the sun.

The remainder of the work is devoted to the planets. The ninth book commences with what concerns them all in general. The planets are much nearer to the earth than the fixed stars and more distant than the sun. Jupiter and Saturn were the next. These three planets are at a greater distance from the earth than the sun.1 So far all astronomers are agreed. This is not the case, he says, with respect to the two remaining planets, Mercury and Venus, which the old astronomers placed nearer to the earth than the sun. He decides in favor of the former opinion, which was indeed that of most mathematicians. The ground of the arrangement of the planets in order of distance was the relative length of their periodic times; the greater the circle, the greater was, it was thought, the time required for a description. Hence we see the origin of the difficulty and the difference of opinion as to the arrangement of the sun, Mercury and Venus, since the times in which, as seen from the earth, they appear to circle the sun, are far greater than the length of time which has elapsed upon the globe itself. Delambre thinks it strange that Ptolemy did not see that these contrary opinions could be reconciled by supposing that the two planets moved in epicycles about the sun; this would be stranger still, that Ptolemy did not see that the revolution of each planet about the sun was a complete circle, and that since it is referred to by Cicero,4 had been that of the Egyptians.5 It may be added, as strangest of all, that this doctrine was held by Theon of Smyrna,6 who was a contemporary of Ptolemy or somewhat younger. And he remarks that Tycho Brahe there is, and that Delambre observes, only a single step.

We have seen that the problem which presented itself to the astronomers of the Alexandrian epoch was the following: it was required to find such a system of equable circular motions that would represent the inequalities in the apparent motions of the sun, moon and the planets. Ptolemy now takes up this question for the planets; he says that "this perfection is of the essence of celestial things, which admit of neither disorder nor inequality,"7 that this planetary system in part of extreme difficulty, and that no one had yet completely succeeded in it. He adds that it was owing to these difficulties that Hipparchus—who loved truth above all things, and who, moreover, had not received from his predecessors observations of great precision—could not say that he has left behind him a system as perfect as the one he had designed, as far as possible, in representing the motions of the sun and moon by circles, but that he had not yet completely determined the theory of the five planets. He was content, Ptolemy continues, to arrange the other planets and to give an account of their motions, and to show whence the phenomena did not agree with the hypotheses of mathematicians at that time. He showed that in fact each planet had two inequalities, which are different for each, that the retrograde motion of each planet takes place, as it were, in a single inequality and the same retrogradation; he showed further that their motions cannot be explained by eccentricities nor by epicycles carried along concentrically, but that it was necessary to consider the epicycle, and that from Hipparchus the periodic motions of the five planets, together with the shortest times of restitutions, in which, moreover, he has made some slight corrections. He then gives tables of the mean motions in longitude and of anomaly of each of the five planets.8

1 This is true of their mean distances; but we know that Mars at opposition is nearer to us than the sun.

2 For example, Tycho Brahe learned from Theon of Smyrna.

3 Transits of Mercury and Venus over the sun's disk, therefore, had not been observed.

4 This was known to Eudoxus. Sir George Cornwell Lewis (In Aristarchus, and the Astronomers of ancient, 1554) says that the geocentric revolutions assigned by Eudoxus to these two planets, with the heliocentric revolutions in the Copernican system, which are of course quite different, says that "the error with respect to Mercury and Venus is considerable"; this, however, is an error not due to Eudoxus but to Ptolemy.

5 "Hunc [solen] ut comites consequitur Veneris alter, alter Mercurii cursus" (Somnium Scipionis, De resp. vi. 17). This hypothesis is alluded to by Ptolemy, N.H. ii. 17, and is more explicitly written by Aratus (Hipparchi canto proeminens in Epigrammatis, 97), although the tradition is that the geocentric revolution is due to Ptolemy himself, Ptolemaic, lib. 176, 193, 194, 195, 196, ed. Halma), is not the same as Theon of Smyrna, on the ground chiefly that the latter was not an observer.

6 Macrobius, Commentarii ex Cicerrone in somniump Scipionem, i. 19.

7 Theon Smyrnaeae Platonici, Liber de astronomia, ed. Th. H. Martin (Paris, 1826), pp. 174, 194, 294, 295. Ptolemy, according to Theon, the mathematician, four of whose observations are used by Ptolemy (Alm. ii. 176, 193, 194, 195, 196, ed. Halma), is not the same as Theon of Smyrna, on the ground chiefly that the latter was not an observer.

8 Delambre compares these mean motions with those of our modern tables and finds them tolerably correct. By "motion in longitude" must be understood the motion of the centre of the epicycle about the eccentric, and by "anomaly" the motion of the star on its epicycle.
GEOGRAPHY

PTOLEMY

vol. iii. (Paris, 1819). (4) 'Ανατολικὴ βυζικὴ'. This Treatise on Music was published in Greek and Latin by Wallis at Oxford (1682). It was afterwards reprinted with Porphiry's commentary in the third volume of Wallis's works (Oxford, 1699). (5) Τετράβιον ουσίας τριτηοπλοική τιταγμάτων. This work is astronomical, as is also the small collection of aphorisms, called Κατάφιλοι ή Κατημνήλοιον, by which it is followed. It is difficult whether these works are genuine, but the doubt merely arises from the feeling that they are not Ptolemy's. They were published in Latin by Camerarius (Nuremberg, 1535), and by Melanchton (Basel, 1553). (6) De anatomate. The original of this work of Ptolemy is lost. It was translated from the Arabic and published by Commandine (Rome, 1525). The Anatomia is the description of the world. (7) Planisphere, The Latin text of this work also is lost, and we have only a Latin translation of it from the Arabic. The 'planisphere' is a projection of the sphere on the equator, the eye being at the plane—in fact what is now called 'stereographic' projection. The best edition of this work is that of Commandine (Venice, 1558).

(8) Optics. This work is known to us only by imperfect manuscripts in Paris and Oxford, which are Latin translations from the Arabic. The Optics is the last book of Ptolemy's, and also the fifth, the least interesting; it is a treatise on light and vision, and deals chiefly with the optical phenomena. It was probably written by Ptolemy himself.

This edition of Ptolemy's works was undertaken at Leipzig. The first volume (in two parts, 1898, 1903) contains the Greek text of the Almagest edited by the late Dr. F. Mentzela, Histoire des mathématiciens (Leipzig, 1883); Fabricius, Bibliotheca græca, ed. Harles, vol. 5; and Halma's 1851-1861 edition of his Almagest (Greek with French translation); A. Berry, A Short History of Astronomy, pp. 62-73; British Museum Catalogue.

Geography.

Ptolemy is hardly less celebrated as a geographer than as an astronomer, and his Geographike syntaks is exercised as great an influence on geographical progress (especially during the period of the Classical Renaissance), as did his Almagest on astronomical. This exceptional position was largely due to its scientific form, which rendered it convenient and easy of reference; but, apart from this, it was really the most considerable attempt of the ancient world to place the study of geography on a scientific basis. The astronomer Hipparchus had indeed pointed out, three centuries before Ptolemy, that the only way to construct a trustworthy map of the inhabited world would be by observations of the latitude and longitude of all the principal points on its surface. But the materials for such a map were almost wholly wanting, and, though Hipparchus made some approach to a correct division of the known world into zones of latitude, 'climates' or 'climate', as he termed them, trustworthy observations of latitude were then very few, while the means of determining longitudes hardly existed. Hence probably it arose that no attempt was made to follow up the suggestion of Hipparchus until Marinus of Tyre, who lived shortly before Ptolemy, and whose work is now lost. But Ptolemy himself, in his Geographike syntaks, exercised himself mostly with determinations derived from itineraries and other rough methods, such as are still employed where more accurate means of determination are not available. The greater part of Marinus's treatise was occupied with the discussion of his authorities, and it is impossible, in the absence of the original work, to decide how far his results attained a scientific form. But Ptolemy himself considered them, on the whole, so satisfactory that he made his predecessor's work the basis of his own in regard to all the Mediterranean countries, that is, in regard to almost all those regions of which he had definite knowledge. In the more remote regions of the world, Ptolemy availed himself of Marinus's information, but with reserve, and himself explains the reasons that induced him sometimes to depart from his predecessor's conclusions. It is unjust to term Ptolemy a plagiarist from Marinus, as he himself fully acknowledges his obligations to that writer, from whom he derived the whole mass of his materials, which he undertook to arrange and present to his readers in a scientific form. It is this form, unique among those ancient geographical treatises which have survived, that constitutes one great merit of Ptolemy's work. At the same time it shows the increased knowledge of Asia and Africa acquired since Strabo and Pliny.

1. Mathematical Geography.—As an astronomer, Ptolemy was of course better qualified to explain the mathematical conditions of the earth and its relations to the celestial bodies than most preceding geographers. His great work was published in the fifth year of the reign of Emperor Hadrian, and was a work of such magnitude that it excited remark among his contemporaries. The Almagest, which contains a description of the apparent movements of the fixed stars and planets, and the fixed stars, to which Ptolemy refers as the origin of the time of the earth; the equator and the tropics—parallel to one another, dividing the earth into two equal parts—were given by the ancients for the name of meridians. He thus, like modern geographers, conceived the whole surface of the earth as covered with a network of parallels and meridians of longitude, terms which he himself did not use in a technical sense. Within the network thus constructed it was his task to place the outline of the world, so far as known to him.

But at the very outset of his attempt he fell into an error vitiating all his conclusions. Eratosthenes (276-196 b.c.) was the first who succeeded scientifically to determine the earth's circumference, and his result of 250,000 (or 252,000) stadia, i.e. 25,000 (25,000) geographical miles, was generally adopted by subsequent geographers, including Strabo. Poseidonius, however, (c. 135-50 b.c.), on the other hand, adopted 40,000 stadia as the value of the circumference, a mile (instead of 600) being taken as the distance which the sun's rays advanced in one hour. Again, the circumference of the earth, as estimated by Eratosthenes, would have been too small if there existed a sufficient number of points of which the position was fixed by observation; but we learn from Ptolemy himself that such observations for latitude were very few, while the means of determining longitudes did not exist. He adopted the positions laid down by him were, with few exceptions, the result of computations from itineraries and the statements of travellers, liable to much greater error in ancient times than at the present day. It depended upon the want of trustworthy bearings, or of determining means of time by (portable) instruments, or of estimating distance at sea, except by the rough estimate of the time employed in sailing from point to point. Even the use of the log was unknown to the ancients. But, great as were the errors resulting from such imperfect means of calculation, they were increased by the permanent error arising from Ptolemy's system of graduation. Thus if he concluded (from itineraries) that two places were 5000 stadia distant, he would place them 10° apart, and thus in fact separate them by 3000 miles.

Another source of permanent error (though of less importance), which affected all his longitudes, arose from his prime meridian. Here also he followed Marinus, who, supposing that the Fortunate Islands were equidistant from the equator and from the prime meridian, divided the world into two equal parts, or 'climates', without computing the length of the earth's circumference. Hence all Ptolemy's longitudes, reckoned eastwards, were about 7° less than they would have been if really measured from the meridian of Ferro, which continued so long in use. This error was the more unfortunate in that the whole of the Mediterranean, which is situated from this imaginary line, but from Alexandria, westwards as far as eastwards (as Ptolemy himself has done in his eighth book), and afterwards reversed, so as to suit the supposed method of computation.

1 Hipparchus pointed out the mode of determining longitudes by observations of eclipses, but the instance to which he referred (of the celebrated eclipse before the battle of Arbela, which was also seen at Carthage) was a mere matter of popular observation, of no scientific value. Yet Ptolemy seems to have known of no other.
The equator was in like manner placed by Ptolemy at a considerable distance from its true geographical position. The place of the equinoctial line was well known to him as a matter of theory, but as no observations could have been made in his day, he could not ascertain the place of the tropic, from which he supposed to pass through Syene. And as he here, as elsewhere, reckoned a degree of latitude as equivalent to 500 stadia, he inevitably made the intersection of the equinoctial line and the tropic of Cancer, placed the former being fixed by observation, he necessarily carried up the supposed place of the equator too high by more than 230 geographical miles. But as he had practically no geographical acquaintance with the equinoctial region, so the error was of little importance.

With Marinus and Ptolemy, as with preceding Greek geographers, the most important line for practical purposes was the parallel of 35° S. latitude. This line, passing through the Mediterranean, Gibraltar Island and the Gulf of Asia, and thus dividing the Mediterranean (as Dicaearchus and his successors usually regarded it) into two, was continued in theory along the chain of Mt. Taurus till it joined a similar parallel running northwards from the latitudes of the Euphrates, it was regarded as constituting the dividing line of the inhabited world, along which the length of the latter must be measured. But so inaccurate were the observations and so imperfect the materials at command, even in regard to the best known regions, that Ptolemy, following Marinus, describes this parallel as passing through Sardinia and Libya, in Sicily, the one being really in 39° 12′ lat., the other in 37° 50′. Still more strangely he places the 18° N. latitude, or the centre of the dividing parallel, while it really lies nearly 1° north of it.

The problem that had especially attracted the attention of geographers from Dicaearchus to Ptolemy was to determine the length of the Mediterranean, the inhabited world between the equator and the parallel of 35° S. latitude. This question was fully discussed by Marinus, who had arrived at conclusions widely different from his predecessors. Towards the north, indeed, there was no great difference of opinion, the latitude of Thule being generally taken at 45° N., and the highest degree of latitude which was placed both by Marinus and Ptolemy in 65° N., not far beyond the true position of the Skellet Islands, which had come to be generally identified with the mysterious Thule of Pytheas. The western extension of the inhabited world was more difficult to determine, since it was, in like manner, determined by the prime meridian drawn through the supposed position of the outermost of the fortunate Islands. But towards the south and east Marinus gave an enormous extension to Africa, Asia, and beyond, and considered that there might be supplementary regions, though Ptolemy reduced Marinos calculations, he retained an exaggerated estimate of their results.

The additions thus made to the estimated dimensions of the known world were indeed in both directions based upon a real extension of knowledge, derived from recent information; but the original statements were so pervaded by misstatement as to give results (in map-construction) differing widely from the truth. The southern extension of the inhabited world was, even by Strabo at the parallel which passed through the eastern extremity of Africa (Capri Guardafui), the Cinnamon Region (Somali- land, at the southern end of the Red Sea, which was situated) which would correspond nearly to that of 10° of true latitude, they supposed to be situated at a distance of 3400 stadia (340 geographical miles) from that of Meroe (the position of which was really accurate) to the south-east, and 900 stadia to the north. Ptolemy, who it is supposed to have visited Egypt, and who it was to the north, Ptolemy assigned to the inhabited world a breadth of nearly 80°, instead of less than 60°, as in Eristathes and Strabo.

It had been a common belief among Greek geographers, from the earliest times, that the eastward extension of the inhabited world greatly exceeded its breadth, but that it was more than twice as great, an unfounded assumption to which their successors seem to have felt themselves bound to conform. This mistake was partly corrected while extending his Africa unduly southward, exag- erated Asia still more grossly eastward. Here also he really possessed a vague advantage in knowledge over all his predecessors, the silk trade with China having led to an acquaintance, though of a vague and general kind, with regions east of the Pamir and Tian Shan, the limits of Asia as previously known to the Greeks. Marinus had learned that traders proceeding eastward from the Stone Tower (Lingshan) to the region of the Great Wall (Chinamir?), had occupied seven months on the journey; thence he calculated that the distance between the two points was 32,600 stadia or 320 geographical miles. Ptolemy, while he points out the erroneous origin of this computation, does not correct it by any real authority, and hence reduced it summarily by one half. He therefore placed Sera (Singanfu?), the easternmost point on his map of Asia, 453 from the Stone Tower, and yet carried the meridian of the inhabited world eastward at 24,000 stadia or 60° of longitude from the Euphrates, reckoning in both cases a degree of longitude (in this latitude) as equivalent to 400 stadia. Both distances were greatly in excess, independently of the inaccuracy of the computation of elongation, which, in the case of the Euphrates, were of course comparatively well known, nor did Ptolemy's calculation of the length of the Mediterranean differ very materially from those of previous Greek geographers, though still no nearer the truth, as was the case with the other meridian. The causes of error combined to make Ptolemy allow 180° long., or 12 hours' interval, between the fortunate Islands meridian and Sera (really about 130°). With Ptolemy's estimating the length and breadth of the known world, Ptolemy attached a very different sense to these terms from that which they had generally borne. Most earlier Greek geographers and "cosmographers" supposed the inhabited world to extend from the latitude of the Euphrates to the parallel of 45°, at the mouth of a circumfluous ocean. This notion (perhaps derived from the Homer: "ocean stream," and certainly not based upon direct observation) was nevertheless in accordance with truth, as great as the extremes of the inhabited world were separated from each other, so great was the distance of the inhabited world from the true ocean, the Euphrates, in this respect went back to Hipparchus, and assumed that the land extended indefinitely north in the case of eastern Europe, east, south-east and north in that of Asia, and south, west and south-west in the case of Africa. His hypothesis that this line was placed in all of these cases an arbitrary limit, beyond which lay the Unknown Land, as he calls it. But if in Africa he was not content with this extension southward; he also prolonged the continent westwards beyond the limits of the inhabited world, and supposed that the coast swung southwards in connexion with south-east Asia, the extent and position of which he wholly misconceived.

In this last case Marinus derived from the voyages of recent nations the Indian seas a knowledge of extensive lands hitherto unknown to the Helleno-Roman world, and Ptolemy acquired more information in this quarter. But he formed a false conception of the bearings of the coasts thus made known, and of the position of the islands which they belonged, and supposed that the carrying the line of coast northwards from the Golden Chersonese (Malay Peninsula) to the land of the Sinae (sea-coast China), he brought it down again between the island of Pylye and the island of Tiberius, reached the latter called Tapatraga—the principal emporium in this part of Asia, and the farthest point known to him—on a supposed coast of unknown extent, but with a direction from north to south, and facing west. But it is probable that this was not the coast of Africa, so as to induce the Indian Ocean as one vast lake, though a mere assumption, is stated by him as definitely as if based upon positive information. It must be noticed that Ptolemy's extension of Asia eastwards, so as to diminish by 50° of longitude the interval between easternmost Asia and westernmost Europe, fostered Columbus' belief that it was possible to reach the former from the latter by direct navigation, crossing the Atlantic.

Ptolemy's errors in the representation of regions are one thing; it is another thing to discover, in regard to the Mediterranean basin, the striking imperfections of his geographical knowledge. Here he had indeed some well-established data for latitudes. That of Carthage, which he placed between 36° and 37° c., and those of Rome, Alexandria and Rhodes were approximately known, all having been observation-centres for distinguished astronomers. The fortunate accident that Rhodes lay on the same parallel as the Euphrates, which was carried in that astronomer's computation, were of great assistance to his knowledge of the two ends of the Inland Sea on the famous parallel of 36° N. Unfortunately Ptolemy, like his predecessors, supposed its course to be almost uniformly through the open sea, ignoring the great mountains of Atlas, which he supposed to be nothing more than a continuation of the Atlas Mountains of Europe.

The erroneous position assigned to Carthage being supposed to rest upon astronomical observation, doubtless determined that of all North Africa. Thus Ptolemy's Mediterranean, from Massilia to the Nile, was a mere straight line, on which the pole was placed (really 64°). He was still more at a loss in respect of latitudes, for which he had no trustworthy observations; yet he came nearer the truth than previous geographers, all of whom had greatly exaggerated the length of the Inland Sea. Their calculation of the latitude of those of Marinus and Ptolemy, could only be founded on the imperfect estimates of mariners; and Ptolemy, in translating these conclusions into scientific form, vitiated his results by his system of...
PTOLEMY

graduation. Thus while Marinus calculated 24,800 stadia as the length of the Mediterranean from the Straits to the Gulf of Issus, this was stated by Ptolemy at 62°, or about 20° too much. Even after correcting the errors in the geographical information, Ptolemy still represented an excess of nearly 500 geographical miles.

Another error which disfigured the eastern portion of Ptolemy's Mediterranean map was the position of Byzantium, which Ptolemy (recognizing its exact location) placed well to the east, thus carrying it up more than 2° above its true position. This pushed the whole Euxine—with whose general form and dimensions he was fairly well acquainted—to far north by the same amount; but his description of surrounding geography is exaggerated or faulty, and that of the Sea of Marmara, the Bosphorus, and the Sea of Marmora (the Sea of Azov), which he also represented as having its direction from south to north; by the combined effect of these two errors he carried up its northern extremity (with the Tanais estuary and the Sea of Azov) to an extent much beyond the actual position of the rivers. Ptolemy, however, was the first writer of antiquity who showed some conception of the relations between the Tanais or Don (usually considered by the ancients as the boundary between Europe and Asia) and the Caspian. He was also the first geographer after Alexander to return to the correct view (found in Herodotus and Aristotle) that the Caspian was an inland sea, without communication with the ocean.

As to north Europe, Ptolemy's views were vague and imperfect. He had indeed more acquaintance with the British Islands than any previous geographer, and showed a remarkable knowledge of certain British coasts, when compared with the statement (1) that Britain is north than any part of Wales, and (2) twisted round the whole of Scotland, so as to make its length from west to east and to place the northern extremities of Britain and Ireland almost on the same parallel of latitude. Even a doubtful Thule (found by the placing of Thule, the Orkneys (Orkney) and the Hebrides (Eubides) indiscriminately on the left or north of Caledonia. Here he was perhaps embarrassed by adopting Marinus' conclusion that the extreme northernmost part of the Caspian Sea was surrounded by the northernmost of all lands. Ptolemy also supposed the northern coast of Germany, beyond the Cambri Chersonese (Denmark), to be the southern shore of the Northern Ocean, with a general direction to the west. Of the almost wholly landlocked Baltic he was entirely ignorant, as well as of the Scandinavian Peninsula; his Scandia is an island smaller than Corse, lying in the true position of southern central Sweden. Some way east of the Vistula, Ptolemy's notes were the beginning of a dissection of regions, which in his system crosses Asia from west to east. This section lines east of the Indian Caucasus, and forms an angle with the Imaus running north.

But the most famous of all regions in Ptolemy's geography is especially faulty, though he shows a greatly increased general knowledge of these regions. For more than a century the commercial relations between western India and Alexandria, the chief eastern emporium of the Roman Empire, had become more important and active than ever before. The tract called the Periplus of the Erythrean Sea, about A.D. 80, contains sailing directions for merchants from the Red Sea to the Indus and Malabar, and even indicates that the coast of the Red Sea has a few small harbours and is a great step beyond Cape Komari (Comorin), which, taken together with its account of the shore-line as far as the Ganges, affords some suggestions at least of a peninsular character for south India. But Ptolemy, in his Liber XXI, a section of the Periplus from Indus to Ganges, an undue extension in latitude, but practically denies anything of an Indian peninsula, placing capes Komaria and Kory (his southernmost points in India) only 4° S. of Barygaza, the real interval being of 158 (geographical) miles, according to Ptolemy's system of graduation, 16° of latitude. This error, distorting the whole appearance of south Asia, is associated with another, but of opposite tendency, in regard to Taprobane (in which ancient names and localities correspond too closely with those of modern Ceylon to be accidental) and the coast of Sinhala (by Ptolemy as Saenassis), to which the Sinhalese now assign the island of Sri Lanka. But Ptolemy's ignorance of the true size of this was exaggerated by most earlier Greek geographers; but Ptolemy extended it through 15° of latitude and 12° of longitude, so as to make it about fourteen times as large as the reality, and brings down its southern extremity more than 2° south of the equator.

Similar distortions in regions beyond the Ganges, concerning which Ptolemy is our only ancient authority, are less surprising. Between the date of the Periplus and that of Marinus it seems probable that Greek geographers had not only crossed the Gangetic gulf and visited the land on the opposite side, which they called the Golden Chersonese, but pushed considerably farther east, to Cattigara. But these commercial voyagers either brought back inaccurate notions, or Ptolemy's preconceptions destroyed the value of their information. For by the time of Ptolemy, maritime expeditions had ventured from the shores of Asia and Africa in a terra magistra south of the Indian Ocean.

In regard to West Africa, we may notice that he conceives this coast as running almost due north and south to 10° N., and then changing the direction of its coastlines. This was perhaps suggested by the general direction of the coast of the Volta, and the westward running of the Gulf of Guinea. But the Fortunate Islands were so important to his system as his prime meridian, he was entirely misinformed about them, and extended the group through more than 5° of latitude, so as to bring the coast southerly to them to the real parallel of the Cape Verde Islands.

In regard to the mathematical construction or projection of his maps, not only was Ptolemy greatly in advance of all his predecessors, but his theoretical skill was also the more beyond the materials to which he applied it. The methods by which he obliterated the difficulty of transferring the delineation of different countries from the spherical surface of the globe to the plane surface of an ordinary map differed little from those in use at the present day, and the errors arising from this cause (apart from those produced by his fundamental error of graduation) were really of little consequence compared with the defective character of his information and conception of the objects of his research. He was thus well aware of his deficiencies in this respect, and, while giving full directions for the scientific construction of a general map, he contents himself, for the special maps of different countries, with giving the general conclusions he arrived at, and the parallels of latitude and meridians of longitude as straight lines, assuming in each case the proportion between the two, as it really stood with respect to some one parallel towards the middle of the regions than was really the case. Such a course, as he himself repeatedly affirms, will not make any material difference within the limits of each special map.

Ptolemy especially devoted himself to the mathematical branch of his subject in the arrangement of his work, in which he has presented an accurate map, as it is, in a tabular form, instead of being at once embodied in a map, was undoubtedly designed to enable the student to construct his maps for himself. This purpose it has abundantly fulfilled. It is what we should have expected, if we consider that he was given to his results their transmission in a comparatively perfect condition to the present day. Unfortunately the specimens of these results have led to the belief that what was stated in the form of general propositions, was intended to convey something more than the truth. Even if this be allowed, there is no doubt that the apparent scientific work of Ptolemy has been shown to be most cases a specious edifice resting upon no adequate foundations.

The work of Ptolemy was the first of its kind accompanied with maps, which are regularly referred to in the eighth book. But how far those which are now extant represent the original series is a disputed point. In the copies of his works which we possess, the maps which accompany them are the work of one Agathodæmon of Alexandria, who "drew them according to the eight books of Claudius Ptolemy." This expression might equally apply to the work of a contemporary draughtman under the eyes of Ptolemy himself, or to that of a skilful geographer at a later period, and nothing is known from any other source concerning this Agathodæmon. The attempt to identify him with a grammairian of the early Christian period is equally unsuccessful. The attempt to find a man of this name is presented in so embarrassing a form, as to perplex rather than assist. Thus Ptolemy's statements concerning the rivers Girs and Nigris, and the lakes and mountains with which they were connected, having been used by several subsequent writers, may perhaps be only said that they present no resemblance to the real features of the country as now known, and cannot be reconciled with them except by arbitrary conjecture.

As to the Nile, both Greeks and Romans had long endeavoured to discover the sources of this river, and an expedition sent out for that purpose by the emperor Nero had undoubtedly penetrated as far
as the marshes of the White Nile in about 5° N. Ptolemy's statement that the Nile derives its waters from two streams which rose in two lakes a little south of the equator was nearer the truth than any of the theories concocted in modern times before the discovery of the lake of Bahr el Ghazal. But in his 7° N., he introduces a range of mountains running east to west, which he calls the Mountains of the Moon, and which, however little understood by Ptolemy, may be considered to represent in a measure the position of the Divitani or Dufuri of the latter part of the first century B.C. (Moschus) and of the Bozi of the third century B.C. (Diodorus), to the west of the Nile delta. Near the mouth of the Nile, Ptolemy was so nearly coincident with the parallel of 40° that he lay a vast region of which apparently he knew nothing, but which he vaguely assumed to extend indefinitely northwards as far as the limits of the desert. The two Arabian geographers, Al-Idrisi and S. ibn Idris, the boundary of Greek geography in this direction, was still the northern limit of all that was really known of Central Asia. Beyond that Ptolemy places many tribes, to which he could assign no definite locality, and mountain ranges which he could only place at hazard. As to south-east Asia, in spite of his misplacement of Cattigara and the Sin theae, we must recognize in the latter name a form of China; from the Sin theae being placed immediately south of the Moluccas, a likely position. The connexion between the two—the Chinese coast known only by maritime voyages, and inland China, known only by continental trade—As to Mediterranean countries, we have seen that Ptolemy professed (in the main) to follow Marinus; the latter, in turn, largely depended on Timotheenes of Rhodes (fl. c. 260 B.C.), the admiral of Ptolemy Philadelphus, as to coasts and maritime distances. Claudius Ptolemy, however, introduced many changes of his own results, some of which he has pointed out though there are doubtless many others which we have no means of detecting. For the interior of the different countries Roman roads and itineraries must have formed the basis of his geographical knowledge, as well as the result of his own travels, and the value of his work, though obvious, is conserved by the importance of the rivers and mountain chains which (in his own phrase) "geographiae a country, Ptolemy deals with this part of his subject in so careless a manner as to be often worse than useless. In Greek geography a river was not necessarily ignored, and the river served as a geographical division; so important a part in its geography are disfigured by some astounding errors; while he does not notice any of the great tributaries of the Nile, though mentioning an obscure streamlet, otherwise unknown, because it happened to be the boundary between two Roman provinces.

Bibliography.—Ptolemy's Geography was printed for the first time in a Latin translation, accompanied with maps, in 1462(1), and numerous other editions followed in the latter part of the 16th and early half of the 17th centuries, but the Greek text did not make its appearance until 1833, when it was published at Basel in quarto, edited by Erasmus. All these early editions were accompanied with textual errors, and are critically worthless. The same may be said of the edition of P. Bertius (Gr. and Lat., Leiden, 1618, Tp.), which was long the standard library edition. It contains a number of maps drawn by Matthæus Merian, as well as (not intended to illustrate Ptolemy) by Ortelius, the Roman Itineraries, including the Tabula peutingeriana, and much other miscellaneous matter. The first actual critical edition of Ptolemy's Geography was that of G. W. Woolley, and G. C. Grashoff (Göttingen, 1845), but this only covered the first six books of the entire eight. The edition of C. F. A. Nobbe (3 vols., Leipzig, 1843), presents the best Greek text of the whole work, and has a useful index. The same may be said of the works compiled from Ptolemy's Didot's Bibliae graecae scriptorum (Clavidi Ptolemaei geographiae; 2 vols., Paris, 1883 and 1901), originally edited by Carl Müller and continued by C. T. Fischer, with a Latin translation and a commentary. This work is so far as possible a literal rendering of the ancient text, as far as it has been possible to decide what Ptolemy's Geography of the British Isles," in Archaeologia, vol. xlviii. (1885); T. G. Rylands, Geography of Ptolemy Elucidated (Dublin, 1893); and a Polish study of Ptolemy's Geography and Sarmatia, in the Historical-Philosophical Series (2) of the Cracow University (1902), vol. xvi. (E. H. B.; C. R. B.)

PTOMAINE POISONING—PUBLICANI

PTOMAINE POISONING (Gr. πτώμα, corpse), a phrase now popularized in the sense of a certain class of food-poisoning. The word "ptomaine" was invented by the Italian chemist Selmi for the basic substances produced in putrefaction. They belong to several classes of chemical compounds. (See Medical Jurisprudence.)

PUERTA (Lat. portæ, from pudes, puder, mature, adult), that period of life at which the generative organs in both sexes become functionally active (see Reproductive System). In northern countries males enter upon sexual maturity between fourteen and sixteen, sometimes not much before the eighteenth year, females between twelve and fourteen. In tropical climates puberty is much earlier. In English common law the age of puberty is conclusively presumed to be fourteen in the male and twelve in the female. Puberty is of much ethnological interest, as being the occasion among many races for feasts and religious ceremonies. In Rome a feast was given to the family and friends: the hair of boys was cut short, a lock being thrown into the fire in honour of Apollo, and one into water as an offering to Neptune. Girls offered their dolls to Venus, and the locks of gold worn round and by boys as well as girls—was taken off and dedicated in the case of the former to Hercules or the household lares, in the case of the latter to Juno. The attainment of puberty is celebrated by sages with ceremonies some of which seem to be directly associated with totemism. The Australian rites of initiation include the raising of those scars on the bodies of clansmen or clanswomen which serve as tribal badges or actually depict the totem. Among many savage peoples lads at puberty undergo a pretence of being killed and brought to life again.

PUBLICANI, literally men employed "in connexion with the revenue," (publicans, from populus, people), or possibly "in the public service," the name given in ancient Rome to a body of nouveau riche who had hitherto made their fortunes by trading, and who, during the period, during which they could farm such property to their own profit, or bought of the state for a fixed sum the right to farm for a term of years the duties due to the treasury from the public land in Italy (see Agrarian Laws) or the land held by Roman subjects in the provinces. In very early times the senate entrusted to officials appointed for the purpose the control of the sale of salt (Livy ii. 9); and it was a natural development from this that the state, instead of appointing officials to manage its monopolies, should let out those monopolies to individuals. A regular system was soon established by which the censor, who held office every fifth year, placed all the sources of public revenue in the hands of certain individuals or companies, who on payment of a fixed sum into the treasury, or on giving adequate security for such payment, received the right to make what profit they could out of the revenues during the five years that should elapse before the next censorship. The assignment was made to the highest bidder at a public auction held by the censor. The same system was applied to the public works, the publicani (or company) in this case being paid a certain sum, in return for which he took entire charge of a certain department of the public works, and winning his appointment by making the lowest tender. That this system was well established at the time of the Second Punic War is assumed in Livy's account of the various offers made by the wealthier class of citizens to relieve the exhausted treasury after the battle of Cannae. On the one hand we have companies offering a price for branches of the public works, which, on the other, offered the state to supply any profit for themselves (Livy xxiii. 49). On the other hand individuals are represented as undertaking the management of public works on the understanding that they will expect no payment until the conclusion of the war (ibid. xxiv. 18).

In very early times the publicani may have been men closely connected with the government. But since wealth was a necessary qualification for the post, and wealth at Rome became more and more confined to the commercial class, the publicani became
Identical with the leading representatives of the class of capitalists and traders. This class was always distinct at Rome from the hereditary nobility which monopolized the government of the state, and members of the senatorial class were excluded from it by definite enactment (see Senate). Although common interest was strong enough to secure for the government in time of external danger the loyal support of the commercial class, yet after the close of the great wars a market hostility grew up between it and the government.

The extension of the Roman system of tax-farming to the provinces did not at first increase the importance of the publicani in Italy; for in the earlier provinces, in which the collection of the revenues was put up to auction in the province itself, the publicani were generally natives. But C. Gracchus, who carried a law that the taxes of the new province of Asia should be put up to auction by the censor in Rome, gave to the Roman capitalists an opportunity of greatly extending their financial operations, and thus in a short time of securing important political powers. It was in their capacity of publicani in the wealthiest provinces that the capitalist or equestrian judges (see Equites) became a menace to the provincial governors who represented the senatorial power. Cicero often applies the name publicani to the whole order; and on the various occasions when the demands of the equestrian party determined the policy of the state we can clearly trace the interests of the publicani, who were involved in an infinite number of commercial and financial transactions in the provinces, as the motive of its action. Thus the cruel fate of the Roman business men in Cirta led the capitalist class to force the Jugurthine War upon the senate in 112 B.C.; the disorganization of Asiatic commerce by the pirates led the same party to support the proposal to confer extraordinary powers on Pompey in 67 B.C.; and the rigour of the senate in opposing any relaxation of the burdetome contracts made by the tax-farmers of Asia in 60 B.C. led to that estrangement between the senate and the capitalist class which enabled the democratic party to work its will and pave the way for the principate.

The companies of publicani continued some of their operations in the provinces under the early principate, but they lost many of their opportunities of oppression and embezzlement. We hear of a vigorous attempt made by Nero to suppress their unjust exactions, and they appear to have been kept under much closer supervision.

The term publicus was applied at this time, and probably earlier, to the subordinate officials employed by the companies of publicani for the actual collection of the revenue, and thus acquired the general sense of "tax-collector," even in provinces where the system of tax-farming by contract with societies of publicani was not in existence.

**PUBLIC HEALTH, LAW OF.** State medicine as an organized department of administration is entirely of modern growth. By the common law of England the only remedy for any act or omission dangerous to health was an action for damages or an indictment for nuisance. The indictment for nuisance still lies for many offences which are now punishable in a summary manner under the powers of modern legislation. But for a long time it was the only, not as now a concurrent, remedy. At a comparatively early date statutes were passed dealing with matters for which the common law had provided too cumbersome a remedy, while the plague called forth the act of 1 Jac. I. c. 31 (1603), which made it a capital offence for an infected person to go abroad after being commanded by the proper authority to keep his house. The act for the rebuilding of London after the great fire, 10 Car. II. c. 3 (1668), contained various provisions as to the height of houses, breadth of streets, construction of sewers and pavements; of noise and trade. Numerous acts of local authorities gave the authorities of the more important towns power over the public health. But it was not until 1848 that a general Public Health Act, embracing the whole of England (except the Metropolis), was passed. The Public Health Act 1848 created a general board of health as the supreme authority in sanitary matters, but greater local sanitary control was given by an act of 1858. The local government board, the present central authority, was created by an act of 1871. Numerous acts dealing with public health were passed from 1840 to 1874; and the law was digested into the Public Health Act 1875, as amended by the Local Government Act 1894 and other acts.

The tendency of English sanitary legislation has been to place local sanitary regulations in the hands of the local authorities, subject to general superintendence by a government department. The jurisdiction of a local authority is both preventive and remedial. The sanitary offices under it are very numerous, but their importance will be found in the article ENGLAND: Local Government. The act of 1875 was followed by the Public Health Acts Amendment Act 1896, the Public Health Act 1896 and the Public Health Acts Amendment Act 1898. The first of these statutes of 1896 enlarged powers on such local authorities as choose to adopt it, the right of adoption being general in the case of urban authorities, and in that of rural authorities limited to certain specified provisions. The Public Health Acts 1896 and 1904 abolished the old system of quarantine (q.v.), and empowered the local government board to make regulations as to the landing or embarking of infected vessels in British or British subjects. It enabled local authorities to adopt many of the useful clauses introduced into private bills from time to time, relating not only to sanitary provisions, but to streets and buildings, milk, &c. supply, recreation grounds, sky-traps, &c.

Other provisions have been made for the notification of infectious diseases by the Infectious Diseases (Notification) Acts 1889 and 1899. The former statute was originally adopted only, but it has now been extended to cover not only the infectious diseases, but all such as are 'notifiable' under the Public Health Act 1875. A London notification has been compulsory since 1891. Reference should be made also to the following statutes: the Infectious Disease (Prevention) Act 1900 provides for the inspection of dairies, and the cleansing and disinfecting of premises, and the regulation of public health (Public Health Act 1896). The local government board may order assign to any port sanitary power or duties arising under this statute. The scope of the Bath and Washhouses Acts 1889 and 1893 was extended by an act passed in 1904, and local health boards are empowered to make further provisions. The Public Health Board Act 1903 enables county councils to recommend the establishment of hospitals for the reception of patients suffering from infectious diseases; the Cleansing of Persons Act 1897 enables local authorities to permit persons to apply to them, on the ground that they are likely to have recourse to various uses of cleansing apparatus; and the Vaccination Acts 1898 and 1907 profoundly modified the law as to vaccination by giving a discretion to magistrates. No less than 1,005, amongst them, the London Bills of Sale Acts, 1889 (fruit vendors), 1896 (epidemics), 1898 (cholera), 1904 (shop hours), 1905 (medical inspection of aliens) and numerous others.

In addition to these statutes, account has to be taken of a large body of legislation which relates indirectly to the law of public health, or at least comes well within its range of operation. It deals with a very great variety of subjects, and only the slighest sketch of its results need be given here. (For factories and workhouses see Factories Act 1896, Workhouses, &c.) The Mines and Workmen (1897) and Miners (1897) Acts regulate the conditions of the work of miners. The Rivers Pollution Prevention (Borders Councils) Act 1958 enables joint committees of English and Scottish county councils of counties on both sides of the Border to exercise the powers of the Rivers Pollution Prevention Act 1957 in relation to any river or tributary which is partly in England and partly in Scotland—an expression including the Tweed. The Notification of Births Act 1907 and the Children Act 1907 (see Children: Law relating to) give great powers to the authorities over persons under 14 years of age. Acts may be made to the Contagious Diseases (Animals) Act 1894, which consolidated the law on this subject.

**London.** Down to the year 1891 London was governed in matters of public health by special statutes (especially the Metropolitan Police Acts), and by provisions in the general statutes. The law as to the Metropolis was consolidated, and is now regulated by the Public Health (London) Act 1891. The sanitary authorities for the execution of the act were the commissioners of sewers for the City of London, the vestries of the larger and the district boards of some of the smaller parishes, and varying authorities for Woolwich and some other places. Under the Public Health Act 1891 the operation of the existing vestry and district board are transferred to the council of the borough comprising the area within the jurisdiction of such vestry and district board; and the borough councils take over certain of the functions of the county council, such as the care of public baths, houses and offensive businesses) and exercise concurrent jurisdiction with it in other matters. Provision is made for the appointment of medical officers of health and sanitary inspectors. The medical officer is for some purposes placed on the footing of a district poor law medical officer, and he cannot be removed without the consent of the local government board. In its structure and substance
the Public Health (London) Act 1891, which consists of 144 sections, closely resembles the general acts (see LONDON, § iv.).

The law of public health in London is also affected by a number of later statutes relating to the Metropolis alone, such as the London Building Regulations Act 1889, the Waterworks Act 1896, the Canals Protection (London) Act 1898, &c.

Scotland.—Sanitary legislation occurs as early as the reign of Alexander III. The Statuta Scotia, c. 14, forbade the deposit of dung and refuse in towns and burghs, or on the common lands; at Berwick, under a penalty of eight shillings. At a later date the act of 1540, c 20, enacted that no flesh was to be slain in Edinburgh on the east side of the Leith Wynd; that of 1621, c. 29, fixed the local jurisdiction of sheriffs and candlemakers. Acts relating to public health in Scotland are now consolidated and amended by the Public Health (Scotland) Act 1897, which, together with the Infectious Diseases Notification Act 1889 and the Bury Police (Scotland) Act 1895, constitute the statutory law of Scottish sanitary administration. The central authority is the local government board for Scotland. The local authorities are—(i.) in burghs under the Bury Police (Scotland) Act 1892, the town council or burgess commissioners; (ii.) in other burghs, the town council or board of police; (iii.) in districts where the county is divided into districts, the district committee; (iv.) in counties not so divided, the county council. The substantive provisions are similar to those of the English acts.

Ireland.—Several acts of the Irish parliament dealt with specific nuisances, e.g. 5 Geo. III. c. 15, forbidding the laying of filth in the streets of cities or county towns, and making regulations as to sweeping and scavenging. The last of these was the Public Health Act 1878, which deals with water-supply and the obstruction of watercourses. In 1878 the existing legislation was consolidated by the Public Health (Ireland) Act 1878, a close copy of the English act of 1875.

Most of the English acts apply to Ireland with modifications and adaptations.

United States.—After the Civil War boards of health were established in the chief cities. Public health is under the control of the local health departments, which are usually elected by the people. At the Annual Meeting of Congress of the 25th of February 1799 officers of the United States are bound to observe the health laws of the states. A national board of health was created by the act of the 3rd of March 1879, and it was succeeded by the Public Health and Marine Hospital Service, whose chief officer is the surgeon-general and which has jurisdiction in quarantine and in epidemics of a peculiarly dangerous nature.

PUBLISHING.

in its general English acception, a house in respect of which a licence has been obtained for the consumption of intoxicating liquors. Public houses are frequently distinguished as "tied" and "free." A tied house is one rented from a person or firm from whom the tenant is compelled to purchase liquors or other commodities to be consumed therein. A free house has no such covenant. The keepers of public houses ("publicans" or "licensed victuallers") are subject, in the conduct of their business, to a number of restrictions laid down by various acts of parliament; while, in order to ply their trade, they require a justices' licence and an excise licence. (See LICQUOR LAWS; TEMPERANCE.)

By the Parliamentary Elections Act 1853 a public house must not be used for elections, meetings or committee rooms. By the Payment of Wages in Public Houses Act 1883 it is illegal to work without a weekly wage, except such wages as are paid by the resident owner or occupier. By the Sheriffs Act (1887) when a debtor is arrested he must not be taken to a public house without his free consent, nor must he be charged with any sum for liquor or food, except what he freely asks for.

PUBLILUS (less correctly PUBLIUS) SYRUS, a Latin writer of maxims, flourished in the 1st century B.C. He was a native of Syria and was brought as a slave to Italy, but by his wit and talent he won the favour of his master, who freed and educated him. His maxims, in which he acted himself, had a great success in the provincial towns of Italy and at the games given by Caesar in 46 B.C. Publius was perhaps even more famous as an improvisatore, and received from Caesar himself the prize in a contest in which he vanquished all his competitors, including the celebrated Decimus Laberius. All that remains of his works is a collection of Sentences (Sententiae), a series of moral maxims in iambic and trochaic verse. This collection must have been made at a very early date, since it was known to Aulus Gellius in the 2nd century A.D. Each maxim is comprised in a single verse, and the verses are arranged in alphabetical order according to their initial letters. In course of time the collection was interpolated with sentences drawn from other writers, especially from apocryphal writings of Seneca; the number of genuine verses is about 700. They include many pithy sayings, such as the famous "judex damnatur ubi voces absolvitur" (adopted as its motto by the Edinburgh Review).

The best texts of the Sentences are those of E. Wülfli (1869) A. Spengel (1874) and W. Meyer (1886), with complete critical apparatus and index verborum; recent editions with notes by J. Friedrich (1880), R. A. H. Bickford-Smith (1895), with full bibliography; see also W. Meyer, Die Sammlungen der Sprachverse des Publius Syrus (1877), an important work.

PUBLISHING. In the technical sense, publishing is the business of producing and placing upon the market printed copies of the work of an author (see BOOK). Before the invention of printing the actual maker of a manuscript was to a great extent his own publisher and his own bookseller. Increase of facilities for the production of copies led to a steady though slow differentiation of functions. The author was the first factor to be isolated and confined to a well-marked province, yet we may find upon the title-page of some old books an indication that they might be purchased either at the shop of the bookseller who published them or at the lodgings of the author.

The separation of publishing from bookselling came later (see BOOKSELLING). Booksellers were the first publishers of printed books, as they had previously been the agents for the production and exchange of authentic manuscript copies; and as they are quite competent to make contracts with paper-makers, printers and bookbinders, there is no particular reason why they should not be publishers still, except the tendency of every commercial business to break up, as it expands, into specialized departments. That tendency may be seen at work in the publishing business itself. When publishers had conquered their own province, and had confined booksellers to bookselling, they held in their own hands the entire business of distributing their works. But a class of wholesale booksellers has grown up, and although important retail booksellers in London continue to deal directly with the publishers, the retail booksellers throughout the country draw their supplies quite largely from the wholesale agents.

The intellectual movement which was largely responsible for the French Revolution, and the general stir and upheaval which followed that portentous cataclysm, precipitated the separation of production from distribution in the book trade, by the mere expansion of the demand for books. That separation was practically complete at the beginning of the 19th century, although it would not be difficult to find survivals of the old order of things at a much later date. The old bookseller-publishers were very useful men in their time. They met fairly the actual needs of the public; and as regards the author, they took the place of the private patron upon whom he had largely depended. They did much to endure at their hands, still, they did undoubtedly improve his status by introducing him to public patronage and placing him upon a sounder economic basis. If in the earlier days they were less than liberal in their terms, it may be remembered that their own business was not very extensive or very remunerative. They were not equipped either with brains or with capital to extend that business in answer to the growing demand for books. By the daily routine of their shops they
were tied down to narrow views, and their timidity is characteristically shown by the fact that to publish a book of any importance required the co-operation of a number of booksellers who shared the expenses and the profits.

Enterprise could not be expected from a committee of that kind and of that composition; hence there was not merely an opportunity, but a clamorous demand for men of larger ideas and wider outlook to undertake the proper business of publishing, unhampered by the narrowing influences of retail trade.

Besides unconsciously improving the position of authors by enabling them to appeal to the public instead of to patrons, whom Johnson classed with other evils in the line "toil, envy, want, the patron and the gaol," the bookseller-publishers gave them, or many of them, steady employment as literary assistants and advisers.

As the demand for books increased, these worthy tradesmen felt with growing acuteness their own want of literary ability and of education. They called in men of letters to supply their own deficiencies. No doubt they expected the lowest kind of hack work from their assistants, no doubt the pay was poor, no doubt they trampled upon the sensitivities of the man of letters, and no doubt he irritated them by his unbusinesslike habits. Still, the association was useful to both parties; and indeed, one may lay down many books at the present day with a sigh of regret that the writers had never been compelled to go through an apprenticeship of the kind.

The emergence of the publishers as a separate class was accompanied by differentiation of the functions of their literary assistants. The routine drudgery which men of education and ability formerly had to undergo fell to a class now known as "proof readers," who are on the watch for typographical errors, grammatical slips, ambiguities of expression, obvious lapses of memory and oversights of all kinds. Men of letters became "publishers' readers," and their duty was to appraise the worth of the manuscripts submitted, and to advise their employers as to the value of the matter, the originality of the treatment, and the excellence of the style. Their advice was also sought upon literary projects that may have suggested themselves to the publishers, and novel suggestions emanating from themselves were welcomed. Men of letters in positions of that kind could obviously exercise very considerable influence over the proceedings of the publishing firms to which they were attached, and many an unknown writer has owed the acceptance of his work to the sympathetic insight of the publishers' reader.

The man of letters as publisher's reader is, however, a transitory phenomenon in the evolution of the publishing business. His primary function is to tell the publisher what is intrinsically good, but probably he has always to some extent discharged the secondary function of advising the publisher as to what it would pay to publish. The qualities which make a man a sound critic of intrinsic worth are quite different from those that make him a good judge of what the public will buy. When books were comparatively few, and when the reading public was comparatively small, select and disposed to give considerable attention to the few books it read, the critical faculty was of more importance than the business one. But when the output of books became large, and when, as the consequence of educational changes, the reading public became numerous, uncritical and hurried and superficial in its reading, the importance of the critical faculty in the publisher's reader dwindled, while the faculty of gauging the public mind and guessing what would sell became increasingly valuable. The publisher's literary adviser belongs to the period when the publishing business had expanded sufficiently to compel the publisher to look for skilled assistance in working more or less up to the older traditions. But when, as is now the case, expansion has gone so far as to swamp the older traditions, and to make publishing a purely commercial affair, the literary reader gives place to the man of business with aptitude for estimating how many copies of a given book can be sold. This is practically recognized by at least one London publisher, who in recent years paid no salary to his reader, but gave him a small commission upon every copy that was sold of any book the publication of which he had recommended. Nothing could more plainly indicate that literary faculty is not wanted, and that the reader's function is to judge, not literary value, but commercial utility.

The market is flooded with books badly written, badly constructed, as poor in matter as in style, hastily flung together, and outrageously padded to suit conventional relations between size and price. They are books which no man of literary taste or judgment could ever recommend for publication on their merits, but they are published, just as crackers are at Christmas, on a calculation that a certain number will find buyers. Even if the publisher sees no prospect of an adequate sale, he publishes the books all the same, upon terms which ensure to him a manufacturing profit and throw the risk of loss upon other shoulders.

There is no reproach, stated or implied, to the publisher. He is merely a man of his age carrying on his business upon terms which the age prescribes through a number of concurrent causes. Any reproach that may fall upon him he invites by sometimes giving himself the airs of one belonging to an earlier age, and claiming credit for acting upon principles that are obsolete.

An author, even if he be an immortal genius, is, from the economic point of view, a producer of raw material. A publisher, however eminent, is from the same point of view a middleman who works up the author's raw material into a saleable form and places it upon the market. The relationship between the two is one that occurs with great frequency in business, always giving rise to efforts by each party to adjust the division of profits for his own advantage. If there be anything peculiar to the publishing business it is that the party who in that business most successfully adjusts matters for his own advantage is liable to be charged by the other with some form of moral obliquity. The diatribes of authors against publishers are familiar to every one; and publishers on their side have some hard things to say about authors, though their sentiments are less piquantly and less publicly expressed. The publisher is usually a more or less capable man of business, while the author is generally—though there are very notable exceptions—quite ignorant of business and apparently incapable of learning the rudiments. It necessarily follows that the author, left to himself, accepts agreements and signs contracts which are much less favourable than they need be to his acquisition of a due share of the profits jointly made by himself and the publisher. What makes his position still worse is the circumstance that each author fights for his own hand, whereas the publishers, although in competition with one another, are also to some extent in combination.

In these circumstances it occurred to Sir Walter Besant and some others that a remedy for this inferiority in position might be found in a combination of authors for mutual help and protection. After a troublesome period of incubation the Society of Authors was established in London in 1883, with Lord Tennyson as its first president, and with a goodly list of 35 vice-presidents. It offered useful assistance to authors ignorant of business in the way of examining contracts, checking publishers' accounts, revising sometimes too liberal estimates of costs of production, and giving advice as to the publishers to be applied to or avoided in any given case. It has no doubt been of great service in checking the abuses of the publishing trade and in compelling the less scrupulous among the publishers to conform more or less exactly to the practice of the more honourable. On general questions such as that of copyright it serves to focus the opinions of authors, though here it has sometimes its interests against the public rather than against the publishers. But the society has never been an effective combination of authors; and indeed the obstacles, material and moral, to such a combination are so great as to render complete success extremely improbable. Nothing could better illustrate this difficulty than the fact that, concurrently with the Society of Authors, a totally different machinery for the furtherance of the interests of authors came into existence. The "literary agent" made his appearance about 1880. He is supposed to be an
expert in all matters pertaining to publishing and to the book market. He takes the author's business affairs entirely into his hands; utilizes the competition among publishers to sell the author's work to the highest bidder; checks accounts, estimates and sales; keeps the author's accounts for him; and charges a commission upon the proceeds. Here we have the author fighting as of old for his own hand. The only difference is that he does his fighting by proxy, hiring a stronger man than himself to deal the blows on his account. There is no question whatever of solidarity with his fellow-authors, and the whole system is a direct negation of the principle upon which the Society of Authors was founded.

On the other hand, both publishers and booksellers have long had the disposition, and to some extent the ability, to co-operate, and the efforts of both sets of men have unfortunately been in the direction of maintaining, if not raising, the price of books to the public. Since the formation of the Publishers' Association in 1850 the publishing trade has been strongly organized on the trade-union pattern, and its operations have been assisted by the less powerful Booksellers' Association. Books, like many other articles, are sold by the makers at list prices, and the retailer's profit is furnished by discounts off these prices. Under such a system competition among retailers takes the form of the sacrifice by the more enterprising of a portion of their discount. They prefer a large sale at a low profit to a small sale at a high profit. It is always the desire of the less enterprising to put an end to this competition by artificial regulations compelling all to sell at the same price.

Many attempts have been made to destroy freedom of dealing in books. In July 1830 twelve hundred booksellers within 21 m. of the London General Post Office signed a stringent agreement not to sell below a certain price. This agreement was broken almost immediately. Another attempt was made in 1852; but at a meeting of distinguished men of letters resolutions were adopted declaring that the principles of the Booksellers' Association of that period were opposed to free trade, and were tyrannical and vexatious in their operations. The Times took an active part in defending and enforcing the conclusions which they sanctioned. The question was eventually referred to a commission, consisting of Lord Campbell, Dean Milman and George Grote, which decided that the regulations were unreasonable and inexpedient, and contrary to the freedom which ought to prevail in commercial transactions. An attempt was also made in 1869 to impose restrictions upon the retail bookseller; but that also failed, mainly by reason of the ineffective organization which the publishers then had at command.

Feeling their hands greatly strengthened by the establishment of their Association, the publishers were emboldened to make another effort to put an end to reductions in the selling price of books. After much discussion between authors, publishers and booksellers, a new scheme was launched on the 1st of January 1900. Books began to be issued at net prices, from which no bookseller was permitted to make any deduction whatever. This decree was enforced by the refusal of all the publishers included in the Association to supply books to any bookseller who should dare to infringe it in the case of a book published by any one of them. In other words, a bookseller offending against one publisher was boycotted by all. Thus, what is known as the "net system" depended absolutely upon the close trade union into which the publishers had organized themselves. The Booksellers' Association signed an agreement to charge the full published price for every net book, but that body had no real power to impose its will upon recalcitrant booksellers. Its assent to the terms of the publishers merely relieved them of the fear of active opposition on the part of the wholesale booksellers and the large retail booksellers, mainly located in London.

All books were not issued at net prices even in 1900, though the practice had extended enormously since it began in 1900. But the principle was applied round. In the case of such books as six-shilling novels the discount price of four shillings and sixpence was treated as the net price, and the usual penalty was inflicted upon those who dared to sell at any lower price, at all events within twelve months of the date of publication.

Owing to the fact that the net system was gradually introduced, net books and discount books being issued side by side with discount books in the majority, the full effect of the innovation was not immediately apparent. But the establishment of The Times Book Club in 1905 brought the system to the test. That Club aimed at giving to the readers of The Times a much more prompt and copious supply of new books than could be obtained from the circulating libraries. The scheme was at first very favourably received by the publishers, who saw in it the promise of largely increased orders for their goods. They obtained these orders, but then something else happened which they had not foreseen. Of the books they issued the vast majority were of ephemeral interest. For a few weeks, sometimes only for a few days, everybody wanted to glance at them, and then the public interest dwindled and died. As the copies ceased to be sold for circulation the Book Club naturally tried to take advantage of the buying demand, which always exists, though it is always repressed by the very high prices charged by publishers in Great Britain. The Book Club sold its surplus copies at reduced prices, and was obliged to do so, since otherwise it would have been swamped with waste paper. But the authors and publishers now rose in arms. Forgetting that they had been paid the full trade price for every copy, they said that the Book Club was spoiling the market, and that a wholesale buyer had no right to sell at the best price he could get. Hence arose what came to be known as the Book War, between The Times and the associated publishers and booksellers, the publishers withdrawing their advertisements from The Times and doing their best to refuse books to the Book Club. The conflict made considerable commotion, and the arguments on both sides were hotly contested.

The question of the effect of the net system on the trade was hotly debated. The Times was against the net system, and the Associated Publishers were for it. The Times thought that the net system would make it impossible for booksellers to sell a book at a profit, and hence would tend to put a stop to the sale of books. The Associated Publishers thought that the net system would tend to put an end to the trade of booksellers, and hence would tend to put a stop to the sale of books.

The Booksellers' Association, dominated by the large booksellers in London and a few great towns, made common cause with the Publishers' Association. Their interests were not affected by the net system, and they saw in the Book Club an energetic competitor. The small booksellers up and down the country are injured, because it is more difficult than ever for them to stock books on which there is a very small margin of profit, and the sale of which they cannot any longer push by the offer of a discount. Formerly, if a book did not sell at the full price, they could sacrifice their profit and even part of what they paid for it, thus saving at least part of their invested capital. Now if a book does not sell at the net price they have to keep it so long that it is probably unsaleable at any price and forms a dead loss. Hence they cannot afford to stock books at all, and that channel of distribution is blocked.

The cast-iron retail price is economically wrong. A bookseller with a large turn-over in the midst of a dense population can afford to sell at a small profit. He finds his reward in increased sales. His action is good for the public, for the author, and for the publisher himself, were he enlightened enough to see it. But a small bookseller in a remote country town cannot afford to sell at an equally low profit, because he has not access to a public large enough to correspondingly increased sales. Yet both are arbitrarily compelled to sell only at a uniform price fixed by the publisher. What makes the matter worse is that there is no cast-iron wholesale price. The small bookseller has to pay more for his books than the large one who buys in dozens of copies. Carriage on his small parcels often eats up what profit is left to him. As he is not allowed to have books "on sale or return," he has no chance whatever; and as a distributing agency the small bookseller has become negligible.

It is not a necessary consequence of the net system that new books should cost the public more than before. If it has become the practice to sell a ten-shilling book for seven shillings and sixpence, and if that practice be thought objectionable, the obvious remedy, supposing publishers to have no other end in view, is to publish the book at the price for which it is sold. But the net system has been used to enforce the sale of the book
at the published price and nothing less, which obviously amounts to compelling the public to pay more than before for the book. Again, if the object were to benefit the retail bookseller by relieving the pressure of competition, it is plain that after abolishing discounts the publishers would charge the same wholesale prices as before to the booksellers. But, on the contrary, they have so adjusted their prices that the retailer gets no more profit upon a book sold net than he formerly obtained from a book of the same published price after allowing a discount. Thus the object and result of the net system is to increase the profits of the publishers at the expense of the public. This has been accomplished at a time when paper is cheaper than at any previous period, and when machinery has reduced the cost of composition, printing and binding to an almost equal extent. It is a remarkable illustration of the power of combination among quasi-monopolists to raise the price of their commodities even in the face of a falling market.

The Book War came to an end in 1908; but though the publishers and booksellers appeared in the result to have brought the Book Club within terms which were satisfactory to them, the whole situation had really been changed. The public for the first time had been educated. Public attention had been forcibly directed to the fact that there is no reason in the nature of things why the price of books should increase, but on the contrary, every reason why they should be cheaper than at any previous period. A certain mystery which had hung over the publishing trade was effectually dispelled. The man in the street learned that books priced to him at six shillings can be produced by the joint labours of the paper maker, the printer, and the bookbinder for about sixpence, and that in many cases the author gets little or nothing out of the difference. There followed a quickening of the public demand for literature at reasonable prices, and enterprising people were found to meet the demand. A vast quantity of good literature, much better than nine-tenths of what is written to-day, has been brought within reach of persons of the smallest incomes. Hundreds of standard works have appeared in convenient and readable editions at a shilling, at sevenpence and even sixpence per volume. These cheap editions have an enormous sale, not only because they are low in price, but because they have permanent value. For the cost of a novel which he will never look at twice, and which perhaps was hardly worth reading once, a man may obtain half a dozen books that have stood the test of time, and that will become the valued companions of his leisure. He gets them too in a form suited not only to his purse, but to the limited storage accommodation at the disposal of the mass of modern readers, who can neither buy nor house the stately editions that adorn the libraries of the wealthy. Thus, in respect of the large class of books read for recreation, we have reached the paradoxical position that cheapness and excellence go hand-in-hand; and that the disparaging adjective frequently linked with "cheap" is more properly associated with dear and pretentious.

Nor does the counter movement stop even here. There is a growing tendency to bring out books of current production in cheap editions, and also to publish the original edition at prices which must give a painful shock to the authors of the net system. Cheap magazines, and the feuilletons which newspapers are adopting from French practice, make considerable inroads upon the province of the six-shilling novel; and as regards more serious books the newspapers now give an amount of information about their contents which goes far to console the public for the prohibitive prices of the books themselves. These movements are developing and will continue to develop, seriously interfering with the plans of those who devised the net system. The combination publishers have never understood that, apart from the very small percentage of works which make real additions to the sum of knowledge or of genuine literary achievement, the reading of the books they turn out is a pastime, which has to compete in public favour with a great variety of other pastimes. They have chosen to make their form of recreation extremely expensive, with the double result that the public turn to others, and that even their own is increasingly supplied by cheaper agencies.

There are certain classes of books which must always be relatively expensive, because they appeal only to students of some particular branch of science or of art or of literature, whose number is not great. But these are books of enduring value. Their price is justified not only by their prolonged service, but by the erudition or the exceptional qualities which go to the writing of them, as well as by the frequently exensive cost of producing them. But as regards the vast output of books which merely amuse an idle hour, the existence of a large body of readers is the only excuse for their appearance, and if they cannot be produced at a low price ensuring an extensive sale they ought not to be produced at all. Thus there is more than a mere money question involved in the contention about price. An artificial system of prices leads to the printing of a vast quantity of trash, which demoralizes the reading public and is a serious obstacle to the success of the better books. Such a system operates, in fact, as a protective duty in favour of mediocrity and even of something worse. It is no defence of such a system that it panders to the vanity of incompetent scribblers, and enables publishers to make money by selling paper that had better have been kept clean.

A rational system of prices would automatically solve some of the difficulties of the book-world. If a book is selling by tens of thousands of copies, as every book printed for pastime ought to do, it would not matter at what price any large buyer chose to resell his purchases. They would only be a drop in the bucket, and all the contention about second-hand prices would disappear.

Then there is the troublesome system of "remainers," that is to say, the unsellable copies of thousands of books published every year. The editions are small enough—probably not more than one thousand copies—yet, in spite of circulating libraries, a third or a half of that modest number remains in the warehouses of the publishers. Sometimes they are sold for about the cost of their flimsy covers; sometimes they simply go to be reduced to their original pulp at the paper mills. If a book has not justified its production, there will be no question of remainders, supposing its supply to have been regulated by the most ordinary prudence. The sale of such a book never stops, and any small surplus of copies can always be got rid of at a small reduction in price.

Towards the end of the 19th century came a large influx into England of American literature, especially fiction. Not only was there a growing appreciation of many American writers, but the attractive "get-up" of American books made its influence felt upon the British market. Some of the American methods of distribution were also introduced into Great Britain, but at first with only partial success. The most successful effort was the sale of important expensive works through the medium of newspapers. Canvassing, which was a common method of distributing books in the United States, met with little support in the United Kingdom, although about the middle of the 19th century a large trade was done through England and Scotland by canvassers, who sold in numbers and on such works as Family Bibles, Daily Devotions, Lives of Christ and Foxe's Book of Martyrs.

The methods of publishing in America are similar to those adopted in Great Britain. The reason why the discount to the booksellers is generally given pro rata according to the number purchased. It is, however, in respect of the means of distribution that the systems of the two countries differ most. In America the general stores to a large extent perform the plan of the English bookseller, and by their energy and extensive advertising a wider public is served. In the distribution of fiction the American plan of "boomming" a book by copious advertising, although expensive, is often the means of inducing a large sale, and of bringing an author's name before the public.

In America the net system, as adopted in Great Britain, was partially introduced into America.

The continental methods of publishing and distributing, especially in Germany, differ, in many respects very materially, from those of Great Britain. In even the smallest German towns there is a bookseller who receives on sale, immediately upon publication, a supply of such new books as he or the publisher may think suitable to his class of book-buyers. The bookseller submits these books
to his customers, and by this method most books issued are at once placed at the disposal of any buyer interested in the particular subject. The large sums spent in other countries upon advertisements are thus saved. At the book fairs held in Leipzig at Easter and Michaelmas the accounts for books sent on sale are made up and paid. In France all books have to be licensed before publication, but the methods of publication differ little from those of other continental countries, in all of which book prices are much lower than in England.

PUCCINI, GIACOMO (1858–1924), Italian operatic composer, was born at Lucca, of a family already distinguished in music; his great-great-grandfather Giacomo, great-grandfather Antonio, grandfather Domenico, and father Michele, being all well known in the art. He was educated at the Milan Conservatorio, but was not allowed to study there, and in 1884 his opera Le Villi was performed at the Teatro del Verme in Milan. His first work, in 1889, was performed at La Scala, and in 1892 his Messa Lasciva in Turin. But it was the production of La Bohème in Turin in 1896 that made him famous, and this opera had a great success everywhere. Tosca followed in 1900, and in 1904 Madame Butterfly confirmed the highest opinions of his talent.

PUCHTA, GEORG FRIEDRICH (1798–1846), German jurist, born at Kadelburg in Bavaria on the 31st of August 1798, came from an old Bohemian Protestant family which had immigrated into Germany to avoid religious persecution. His father, Wolfgang Heinrich Puchta (1760-1845), a lawyer and district judge, imbued his son with legal conceptions and principles. From 1811 to 1816 young Puchta attended the gymnasium at Nuremberg, where he acquired a taste for Hegelianism. In 1816 he went to the university of Erlangen, where, in addition to being initiated by his father into legal practice, he fell under the influence of the writings of Savigny and Niebuhr. Taking his doctor's degree at Erlangen, he established himself here in 1820 as privadoent, and in 1823 was made professor extraordinary of law. In 1828 he was appointed ordinary professor of Roman law at Munich. In 1835 he was appointed to the chair of civil Roman and ecclesiastical law at Marburg, and he left this for Leipzig in 1837, and in 1842 he succeeded Savigny at Berlin. In 1845 Puchta was made a member of the council of state (Staatsrat) and of the legislative commission (Gesetzgebungskommission). He died at Berlin on the 8th of January 1846. His chief merit as a jurist lay in breaking with past unsatisfactory methods in the teaching of Roman law and in making its spirit intelligible to students. Among his writings must be especially mentioned Lehrbuch der Pandektik (Leipzig, 1838, and many later editions), in which he elucidated the dogmatic essence of Roman law in a manner never before attempted; and the Kursus der Institute (Leipzig, 1847–1847, and later editions), which gives a clear picture of the organic development of law among the Romans. Among his other writings are Das Gewohnheitsrecht (Erlangen, 1828–1837); and Einleitung in das Recht der Kirche (Leipzig, 1840).

Puchta's Kleines zivilistisches Schriften (posthumously published in 1851 by Professor A. A. Friedrich Rudorff), is a collection of thirty-eight masterly essays on various branches of Roman law, and the preface contains a sympathetic biographical sketch of the jurist. See also Zecher, Über die von Puchta der Darstellung des römischen Rechts zu Grunde gelegten rechtspolitischen Ansichten (1853).

PÜCKER-MUSKAU, HERMANN LUDWIG HEINRICH, Fürst von (1785–1871), German author, was born at Muskaú in Lusatia on the 30th of October 1785. He served for some time in the bodyguard at Dresden, and afterwards travelled in France and Italy. In 1811, after the death of his father, he inherited the barony of Muskaú and a considerable fortune. Among his many literary works is Neu Deutschland, a novel, and he fought himself in the war of liberation and was made military and civil governor of Bruges. After the war he retired from the army and visited England, where he remained about a year. In 1823, in compensation for certain privileges which he resigned, he was raised to the rank of Fürst by the king of Prussia. Some years earlier he had married the Gräfin von Pappenheim, daughter of Fürst von Hardenberg; in 1826 the marriage was legally dissolved though the parties did not separate. He again visited England and travelled in America and Asia Minor, living after his return at Muskaú, which he spent much time in cultivating and improving. In 1845 he sold this estate to Prince Frederick of the Netherlands, and although he afterwards lived from time to time at various places in Germany and Italy, his principal residence was his seat, Schloss Branitz near Kottbus, where he laid out splendid gardens as he had already done at Muskaú. In 1863 he was made an hereditary member of the Prussian Herrenhaus, and in 1866 he attended the Prussian general staff in the war with Austria. He died at Branitz on the 4th of February 1871, and, in accordance with instructions in his will, his body was cremated. As a writer of books of travel he held a high position, his power of observation being keen and his style lucid and animated. His first work was Briefe eines Verstorbenden (4 vols., 1830–1831), in which he expressed many independent judgments about England and other countries he had visited and about prominent persons whom he had met. Among his later books of travel were Semilassos vorletzter Weltgang (3 vols., 1835), Semilasso in Afrika (5 vols., 1836), Aus Memhed-Alis Reich (3 vols. 1844) and Die Rückkehr (3 vols., 1846–1848). He was also the author of Andeutungen über Landschaftsgärnerei (1834).

See Ludmilla Assing, Pückler-Muskau Briefeuechel and Tagebücher (9 vols., 1873–1876); Fürst Hermann von Pückler-Muskau (1873); and Petzold, Herrn von Pückler-Muskau in seiner Bedeutung für die bildende Gartenkunst (1874).

PUDDING, a term, now of rather wide application, for a dish consisting of boiled flour enclosing or containing meat, vegetables or fruit, or of batter, rice, sago or other farinaceous foods boiled or baked with milk and eggs. Properly a pudding should be one boiled in a cloth or bag. There are countless varieties, of which the most familiar are the Christmas plum-pudding, the Yorkshire pudding and the suet pudding. The word was originally and is still so used in Scotland for the entrails of the pig or other animal stuffed with meat, minced, flavoured and mixed with oatmeal and boiled. The etymology is obscure. The French boudein occurs in the Scottish original sense at the same time as puding (13th century) in English. Pudin has been connected with Italian boldone and Latin botulus, sausage, but the origins of these words are quite doubtful. Attempts have been made to find the origin in a stem pud-, to swell, cf. "podgy," L. Ger. Pudde-wurst, black-pudding, &c.

PUDSEY, a municipal borough in the Pudsey parliamentary division of the West Riding of Yorkshire, England, 6 m. by S. of Leeds, on the Great Northern railway. Pop. (1891), 13,444; (1901), 14,066; (1911), 14,409. The town is situated on the western outskirts of Leeds. St. Lawrence in Gothic style, erected in 1821, and the mechanics' institute, a fine building, comprising class-rooms, a library, a public hall and a lecture hall. A public park was opened in 1889. The town has an important woollen trade and possesses dying and fuling mills. Part of the parish, Tyersall, is in the borough of Bradford. Pudsey is mentioned in Domesday. It was sold by Edward II. to the Calverley family, from which it passed to an ancestor of the Milners. The town was incorporated in 1899, and the corporation consists of a mayor, 6 aldermen and 18 councillors. Area, 2,399 acres.

PUDUKKOTTAI, a state of southern India, in subdivision to Madras, lying between the British districts of Tanjore and Madura. Area, 1,100 sq. m. Pop. (1901), 380,440, showing an increase of 2% in the decade. The state consists mainly of an undulating plain, nowhere of great fertility and in many parts barren; it is interspersed with rocky hills, especially in the southwest. Granite and laterite are quarried, red ochre is worked, and silk and cotton fabrics, bell-metal vessels and perfumes are among the principal manufactures. There is also some export trade in charcoal. The chief place is Pondicherry, of this town is Pondicherry, the capital of the state is Puducherry, which is also the chief town. The chief, whose title is etamandam, is of the Kallan or robber caste. His ancestors were granted a grant of territory for loyal services to the British during the wars in the Carnatic at the end of the 18th century. Estimated gross revenue, £80,000; no tribute. The state has for some years past been well administered under a council, with a representative assembly. The town of Pudukkottai had a population in 1901 of 20,347. It is well laid out, and contains several fine new buildings.
PUEBLA—PUELCHE

PUEBLA, a state of Mexico, occupying the south-east angle of the great central plateau, or that part of it known as the Anahuac table-land. It is bounded N. and E. by the state of Vera Cruz, S. by the states of Oaxaca and Guerrero, and W. by the states of Morelos, Mexico, Tlaxcala and Hidalgo. Area, 12,204 sq. m. Pop. (1900), 1,021,133, largely civilized Indians. Lofty mountains overlook the plateau from the north-east and west, three of the highest peaks, Orizaba, Popocatepetl and Ixtaccihuatl rising above the permanent snow-line, while another, Malinche, lifts its isolated mass nearly to that limit. In the south the table-land breaks away and long fertile valleys lead downward toward the warm southern plains. The central table-land forms part of the watershed between the eastern and western drainage systems, some of the streams in the north and south-east emptying into the Gulf of Mexico, while the Atoyac, which has its source in Tlaxcala, crosses the state and discharges into the Pacific through the Mesca. Puebla has a temperate, healthful climate, one of the best in Mexico. The soil is generally fertile and the rainfall abundant. Agriculture is the principal industry. The Mexican, Interocéanic and Mexican Southern railways cross the state and afford ample transportation facilities.

PUEBLA (full title La Puebla de los Ángeles, and more recently, Puebla de Zaragoza), a city of Mexico and capital of the state of the same name, on the banks of the Atoyac river, 60 m. S.E. of the city of Mexico, with which it is connected by two lines of railway. Pop. (1900), 93,152, including a large percentage of Indians. Its railway connexions put it in daily communication with the national capital, Vera Cruz, Pachuca, Oaxaca, and the terminal ports of the Tehuantepec railway—Coatzacoalcos and Salina Cruz. The city is built on a broad healthy plain, about 7200 ft. above sea-level. It is well provided with street railways, electric and gas illumination, water and drainage. The great Doric cathedral, about 165 X 320 ft., is perhaps the finest ecclesiastical building in Latin America. It was begun about 1552, but not completed until 1649. Among other churches, famous for their lavish decorations, are those of San José, San Cristóbal, Santa Catarina and San Domingo. The "Teatro Principal," built in 1790, is said to be the oldest existing theatre on the continent. There are two other theatres, and an immense bull-ring. Among the more conspicuous public buildings are the palace of justice, the building of the state legislature, a school of medicine to which is attached the Palafaxiana Library of over 100,000 volumes, an academy of fine arts, and the national college. At Fort Guadalupe, near the city, there are several hot sulphur springs, which are used for medicinal baths. Puebla is one of the busiest manufacturing cities in Mexico, and among its products are cotton and woolen textiles, soap, glass, straw hats, potteries, and other goods. There are also some large foundries.

Puebla was founded in 1532 by Sebastian Ramirez de Fuenel, archbishop of Santo Domingo, and the celebrated Franciscan friar Toribio Motolinia. In 1550 it became the see of the bishopric originally created in 1526 at Tlaxcala. The appellation "de los Ángeles," which is now practically dropped, originated in a popular belief that during the building of the cathedral two angels every night added as much to the height of the walls as the workmen had completed on the preceding day. Its present title was given in honour of General Ignacio Zaragoza (1829-1862), who successfully defended the city against the first French attack in 1862. It was captured in the following year by the French, and then by the Mexicans under Porfirio Diaz in 1867. In the war between Mexico and the United States it was captured by General Winfield Scott and was his headquarters from June to August 1847.

PUEBLO, a city and the county-seat of Pueblo county, the second largest city of Colorado, U.S.A., and one of the most important industrial centres west of the Missouri river, situated on the Arkansas river, about 120 m. S. by E. of Denver. Pop. (1890), 24,558; (1900), 28,157, of whom 4705 were foreign-born, 1250 being Austrian, 587 German, 529 Italian, 415 Irish, 391 Swedish, 385 English and 341 English Canadian; (1910, census), 44,395. It is served by five great continental railway systems—the Denver & Rio Grande, the Atchison, Topeka & Santa Fé, the Missouri Pacific, the Chicago, Rock Island & Pacific and the Colorado & Southern, giving it altogether a dozen outlets. It lies about 4680 ft. above the sea, in a valley at the junction of the prairies with the foothills of the Rockies, on both banks of the Arkansas river, near its confluence with Fountain Creek; the city has an exceptionally good climate and attracts many winter visitors. There are a state insane asylum and four hospitals, of which the Minnequa Hospital (for the employees of the Colorado Fuel & Iron Co.) and St Mary's Hospital are the most notable. Among the public buildings are the McClelland public library (1891) and the court-house, the latter of white stone quarried in the vicinity. The Mineral Palace (1891), having a roof formed of twenty-eight domes, in the northern part of the city, contains a collection of the minerals of the state. Pueblo is chiefly an industrial city, and is often called the Steel City, or the Pittsburg of the West. Cheap fuel is furnished by the excellent coal of Canyon City (about 30 m. west), Walsenburg (about 40 m. south-west) and Trinidad (about 75 m. south). Petroleum deposits in the immediate vicinity are of growing importance. Flushing material is only about 50 m. away, around Cripple Creek. The rich river valley yields abundant crops of alfalfa, sugar beets, cantaloupes, apples and peaches, and the dry lands behind its shores prove fertile under irrigation or under the Campbell system of dry farming; on the plains livestock interests are important. In 1905 Pueblo's total factory products were valued at $2,197,293 (an increase of 32.6% since 1900); if the output of the great smelting and refining establishments just outside the city limits had been included, the value would have been considerably larger. Pueblo is the greatest smelting centre west of the Missouri and probably the greatest in the United States. The bulk of the steel rails used on western railways are from the mills of the Pueblo district.

Pueblo was originally a Mexican settlement. A considerable body of Mormons settled here temporarily on their way to Utah in 1846-1847, and a trading post was established in 1850; but the site, owing principally to Indian troubles, had been practically abandoned before 1858, when another settlement was made on the Fontaine qui Bouille, or Fountain Creek. Two years later Pueblo was surveyed and platted. The first railway—the Denver & Rio Grande—came through in 1872. Pueblo was chartered as a city in 1870, and again, with an enlarged area, in 1887.

PUEBLO INDIANS, the Spanish name (pueblo= village) for the town-building tribes of American Indians of the Keresan, Shoshonean, Tanoan and Zuñian stocks, whose representatives are now practically confined to New Mexico and Arizona. Formerly they had a far greater range. They were alike in their sedentary agricultural characteristics, and had not the warlike disposition of the Plains Indians. Their modern history begins with their discovery in 1539 by Father Marcos de Niza. In the following year they were subdued by Francisco Vasquez de Coronado. Two years later they made a successful revolt, but in 1586 they had again to submit. In 1680 they once more rebelled, but by 1692 they were finally conquered. Their houses are communal, generally but one structure for the whole village. These houses are sometimes built of stone, but oftener of adobe, several stores high, each storey receding from the one below. The common plan is a hollow square or curved figure, though in some cases the form of a pyramid is followed. A feature of each town is the underground chamber used for tribal ceremonies. Many of the towns are built on high table-lands inaccessible except by steep trails. The Pueblos are a short, sturdy type of American Indians, very active, but mild-mannered and much darker than their neighbors. They are farmers and herdsmen, and are skilful in basket-work, weaving, pottery and carving. They are notable for their highly developed ceremonial customs, and their blankets and earthenware are decorated with religious symbolism.

PUELCHE, a tribe of South-American Indians of Araucanian stock. Their home is the Pampas region of southern Argentina around the Colorado river. They are chiefly nomadic, breeding cattle and horses, and lead a wild, lawless life.
PUENTEAREAS, a town of north-western Spain in the province of Pontevedra; on the Tuy-Santiago de Compostella railway and on the river Tea, a right-hand tributary of the Miño. Pop. (1900), 13,452. Puenteareas is the chief town of a fertile hilly region, which produces wine, grain and fruit, and contains many cattle farms. The industries of the town itself are porcelain manufactures, tanning and distilling. Close by are the ruins of the castle of Sobroso, which played an important part in the medieval civil wars.

PUENTE GENIL, or PUENTE JENIL, a town of southern Spain, in the province of Cordova; on the right bank of the river Genil or Jenil, a tributary of the Guadalquivir. Pop. (1900), 12,956. Puente Genil is on the Cordova-Malaga railway, and is the starting-point of the line to Linares. A bridge across the Genil, from which the name of the town is derived, joins the lower part of Puente Genil with the higher, which is built on rising ground extending to the olive groves above. There are several convents, schools for primary and higher education, hospitals, a municipal library and a theatre. The principal industry is the manufacture of olive oil. There are also flour-mills and linen factories. The alkondiga or permanent market is always well stocked with grain, vegetables and livestock.

PuERPERAL FEVER (Lat. puera, from puér, child, and pare, to bring forth), the name given to the varieties of general infection, long regarded as a specific disease ('child-bed fever,' "lying-in fever"), to which women are subject after parturition, owing to the genital tract being peculiarly exposed, in septic surroundings, to the invasion of pathogenic bacteria (see SEPIS). Owing largely to the labours of I. P. Semmelweis (q.v.) the grave mortality formerly attending this condition has been enormously reduced; and the necessity of rigid cleanliness in the treatment of lying-in cases is fully recognised. When unhappily this is not the case, and infection takes place, its complications must be treated according to the circumstances, antiseptic douching being employed, or preferably curetting the endometrium with a sharp curette and swabbing with disinfectant solution. In definitely septicamia cases antistreptococceum serum may be useful.

PUERTO CABELO, a city and port of Venezuela, in the state of Carabobo, 20 m. N. by W. of Valencia, the capital of the state. Pop. (1891), 10,145. Puerto Cabello has railway connexions with Valencia and Caracas. It stands on a small peninsula which partly shelters a large bay, called " Golfo Triste," by the early Spanish navigators. After La Guaya the harbour is the principal port of Venezuela, and it is provided with mole, wharves, railway communication with the interior, and other facilities for the handling of merchandise and produce. The town and harbour were strongly fortified in colonial times, but the port defences were greatly damaged in 1902 in a bombardment by some German vessels of the allied blockading fleet. Among the exports are coffee, tobacco, coffee-plantations, rice, tobacco, sugar, indigo, sarsaparilla, hay, copper and copper ores. Puerto Cabello suffered much in the War of Independence, changing hands several times and remaining in the possession of Spain down to 1823.

PUERTO CORTES (Cortez or Caballos), a seaport on the Atlantic coast of Honduras; in 5° 51' N. and 87° 56' W., at the northern terminus of the transcontinental railway from Fonseca Bay, and near the mouth of the river Chamaleon. Pop. (1905), about 2,500. The harbour, an inlet of the Gulf of Honduras, is deep, spacious and secure, and there is a railway pier at which vessels can load and discharge. The exports include bananas, coffee, cabinet woods, rubber, sarsaparilla, livestock, deerskins and gold. The harbour was discovered in 1527 by Gonzalo d'Avila, and the town was founded a few years later by order of Hernando Cortes, from whom it derives its name.

PUERTO DE SANTA MARIA, a seaport of southern Spain, in the province of Cadiz, on the right bank of the river Guadalete, with a station on the railway from Cadiz to Seville. Pop. (1900), 20,120. Puerto de Santa Maria, commonly called " El Puerto," is probably the Menestheoi Portus of Ptolemy. Its most important industry is the wine trade; there are also glass, liqueur, alcohol, starch and soap manufacturers. The principal buildings are a Moorish citadel, a Gothic church founded in the 13th century, a Jesuit college, and a bull-ring which accommodates 12,000 spectators. The town is noted for its bull-fights, that given here in honour of Wellington being the subject of the considerably idealized description in Byron's Childe Harold.

PUERTO PRINCE (officially, Camagüey), a city and the capital of the province of Camagüey in east-central Cuba, about 528 m. E.E.S. of Havana. Pop. (1899), 25,702; (1907), 29,616. In addition to the axis-railway of the island, which connects it with Havana and Santiago, the city has connexion by a branch line with Nuevitas. Puerto Príncipe lies on a broad plain about equally distant from the north and south coasts of the island, and between two small rivers, the Tinima and Hatibonica. In appearance it is one of the most ancient of Cuban towns. Many of the churches, convents and other ecclesiastical establishments were built in the second half of the 18th century, some on the site of the old fort; and some parts of the original cathedral of 1617 have probably survived later alterations and additions. Some of the bridges, too, built in the 18th century, are picturesque. The city was begun in 1733. There is a provincial institute for secondary education. The city is the seat of a court of appeal. Puerto Príncipe is connected by railway, 47 m. long, with its port, Nuevitas (pop. in 1907, 4,436), which is on the north side of the island and has a spacious land-locked bay of good depth, approached through a break in the off-lying coral keys and a narrow canyon entrance. About 50 m. south of Puerto Príncipe is Santa Cruz del Sur (pop. in 1907, 1,640) on the south coast. Cabinet woods, fruit, tobacco, sugar, wax, honey and cattle products are the leading exports. In 1514 Diego Velasquez founded, on Nuevitas Bay (then known as the Puerto del Príncipe), a settlement that was moved in 1515 or 1516 to the site of the present city of Puerto Príncipe (or Santa Maria del Puerto del Príncipe). From very early times the surrounding plains were given over to horse and cattle-raising. As early as the beginning of the 17th century Havana depended on this supply to furnish the fleets of royal ships which monopolized trade between Spain and America. From very early times too, a prosperous clandestine trade was maintained with Providence, the Bahamas, and especially with Curacao and Jamaica (after its capture by the English in 1655). After the capital, Puerto Príncipe was the richest prize of the island when it was captured and plundered in 1668 by a force of Frenchmen and Englishmen under Henry Morgan, the buccaneer. In the 18th century land grants and illicit trade led to serious disturbances. In 1775 Nuevitas was resettled, and in 1780 was made a legal (habilitado) port. After the cession of Santo Domingo to France in 1800, the Real Audiencia, the supreme court of the Spanish West Indies, was removed to Puerto Príncipe. A superior audiencia was created for Havana in 1838, but the older court continued to exist without the title. Puerto Príncipe boasts of being the most Creole of Cuban cities. It was prominent in the war of 1868-78 and in the insurrection preceding and following it.

PUERTO REAL, a seaport of southern Spain, in the province of Cadiz; on the north shore of the inner arm of the Bay of Cadiz and on the Seville-Cadiz railway. Pop. (1900), 10,535. Puerto Real (Port Royal) is the Portus Gaditnius of the Romans, and is probably the most ancient trading-station on the Bay of Cadiz. It owes its modern name to the fact that it was rebuilt in 1488 by Ferdinand and Isabella. The port has good quays, a dry dock of the Spanish Transatlantic Company, connected with their important works, and safe anchorage close to the wharves for the largest steamers. The town has fine squares, and broad, well-built streets, a handsome town-hall, many schools, a bullring, several convents, and a 16th-century Gothic parish church, with three naves and a remarkable atrium. There is an active trade in wine and oil; the industries are the construction and repairing of ships, and the production of salt.

PUFENDORF, SAMUEL (1636-1684), German jurist, was born at Chemnitz, Saxony, on the 8th of January 1632. His father was a Lutheran pastor, and he himself was destined for the ministry. Educated at Grimma, he was sent to study theology
at the university of Leipzig. Its narrow and dogmatic teaching was profoundly repugnant to him, and he soon abandoned it for the study of public law. He went so far as to quit Leipzig altogether, and betook himself to Jena, where he formed an intimate friendship with Erhard Weigel the mathematician, whose influence helped to develop his remarkable independence of character. Pufendorf quitted Jena in 1637 and became a tutor in the family of Petrus Julius Coyet, one of the resident ministers of Charles Gustavus, king of Sweden, at Copenhagen. At this time Charles Gustavus was endeavouring to impose upon Denmark a burdensome alliance, and in the middle of the negotiations he brutally opened hostilities. The anger of the Danes was turned against the envoys of the Swedish sovereign; Coyet, it is true, succeeded in escaping, but the second minister, Steno Bjelke, and the whole suite were arrested and thrown into prison. Pufendorf shared this misfortune, and was subjected to a strict captivity of eight months' duration. He occupied himself during this time in meditating upon what he had read in the works of Grotius and Hobbes. He mentally constructed a system of universal law; and, when, at the end of his captivity, he accompanied his pupils, the sons of Coyet, to the university of Leiden, he was enabled to publish, in 1661, the fruits of his reflections under the title of Elementa jurisprudentiae universalis, libri duo. The work was dedicated to Charles Louis, elector palatine, who created for Pufendorf at Heidelberg a new chair, that of the law of nature and nations, the first of the kind in the world. In 1669 he wrote, with the assent of the elector palatine, a tract, De statu imperii germanici, liber unus. Published under the cover of a pseudonym at Geneva in 1667, it was supposed to be addressed by a gentleman of Verona, Severinus de Monzambano, to his brother Lælius. The pamphlet made a great sensation. Its author directly arraigned the organization of the Holy Roman Empire and exposed its feebleness, denounced in no measured terms the faults of the house of Austria, and attacked with remonstrance the imperial politics of France. But in 1670 Pufendorf, Philipp Bogislaw von Chemnitz, publicist and soldier, had written, under the pseudonym of “Hippolytus a Lapide,” De ratione status in imperio nostro romanom-germanico. Inimical, like Pufendorf, to the house of Austria, Chemnitz had gone so far as to make an appeal to France and Sweden. Pufendorf, on the contrary, rejected all idea of foreign intervention, and advocated that of national initiative. In 1670 Pufendorf was called to the university of Lund. His sojourn there was fruitful. In 1672 appeared the De jure naturae et gentium, libri octo, and in 1675 a résumé of it under the title of De officio hominis et civis. In the De jure naturae et gentium Pufendorf took up in great measure the theories of Grotius and sought to complete them by means of the doctrines of Hobbes and of his own ideas. His first important point was that natural law does not extend beyond the limits of this life and that it confines itself to regulating external acts. He combated Hobbes' conception of the state of nature and converted the idea of human society as one of the necessary causes of the peace. But this peace is feeble and insecure, and if something else does not come to its aid it can do very little for the preservation of mankind. As regards public law Pufendorf, while recognizing in it the force of the natural (civili et moralis) right, still insists of the will of the state is but the sum of the individual wills that constitute it, and that this association explains the state. In this a priori conception, in which he scarcely gives proof of historical insight, he shows himself as one of the precursors of Rousseau and of the Contract social. Pufendorf powerfully defends the idea that international law is not restricted to Christendom, but constitutes a common bond between all nations because all nations form part of humanity.

In 1677 Pufendorf was called to Stockholm as historiographer-royal. To this new period belong Einleitung zur Historie der vormoralischen und Staatlichen lamen vom Ancien, libri V.; ab expeditione Gustavi Adolphi regis in Germaniam ad olimnationem usque Christianii et De libri C. De carolo Gustavi gestis. In his historical works Pufendorf is hopelessly dry; but he professes a great respect for truth and generally draws from archives. In his De habitu religionis christianae od vitam cievem he traces the limits between ecclesiastical and civil power. This work propounded for the first time the so-called "collegial" theory of church government (Kollegalialsystem), which, developed later by the learned Lutheran theologian Christoph Mathäus Pfaff (1686-1760), formed the basis of the relations of church and state in Germany and more especially in Prussia.

This theory makes a fundamental distinction between the supreme jurisdiction in ecclesiastical matters (Kirchenhoheit oder jus circa sacra), which it conceives as inherent in the power of the state in respect of every religious community, and the so-called "legal jurisdiction" (Kirchengewalt oder jus in se) inherent in the church, but in some cases vested in the state by tacit or expressed consent of the ecclesiastical body. The theory was of importance because, by distinguishing church from state while preserving the essential supremacy of the state, it prepared the way for the principle of toleration. It was put into practice to a certain extent in Prussia in the 18th century; but it was not till the political changes of the 19th century led to a great mixture of confessions under the power of the government, that it was put into practice by the Protestant governments to make a working compromise with Rome in respect of the Catholic Church established in their states.

In 1688 Pufendorf was called to the service of Frederick William, elector of Brandenburg. He accepted the call, but he had no sooner arrived than the elector died. His son Frederick III. fulfilled the promises of his father; and Pufendorf, historiographer and privy councelor, was instructed to write a history of the Elector Frederick William (De rebus gestis Frederici Wilhelmi Magni). The king of Sweden did not on this account cease to testify his goodwill towards Pufendorf, and in 1694 he created him a baron. In the same year, on the 26th of October, Pufendorf died at Berlin and was buried in the church of St Nicholas, where an inscription to his memory is still to be seen.

Pufendorf was at once philosopher, lawyer, economist, historian and statesman. His influence was considerable, and he has left a profound impression on thought, not only on that of Germany but for the world. But the value of his work was much under-estimated by posterity. Much of the enthusiasm with which he was received rests with Leibnitz, who would never recognize the incontestable greatness of one who was constantly his adversary, and whom he dismissed as "viv parum jurisconsultus et minime philosophus." It was on the subject of the pamphlet of Severinus de Monzambano that their quarrel began. The conservative and timid Leibnitz was beaten on the battlefield of politics and public law, and the aggressive spirit of Pufendorf aggravated yet more the dispute, and so widened the division. From that time the two writers could never meet on a common subject without attacking each other.

PUFF-BALL, in botany, the common name for a genus of fungi (known botanically as Lycoperdon), and so called because of the cloud of brown dust-like spores which are emitted when the mature plant bursts. They are common in meadows and woods and on heaths or lawns, and when young resemble white balls, sometimes with a short stalk, and are fleshy in texture. If cut across in this state, they show a compact rind enclosing a loose tissue, in the interspaces of which the spores are developed; as the fungus matures it changes to yellowish-brown and brown and when ripe the rind tears at the apex and the spores escape through the aperture when any pressure is applied to the ball. When white and fleshy the fungus is edible. The fibrous mass which is produced after the spores have been used for tinder or as a stptic for wounds. The giant puff-ball, Lycoperdon giganteum, reaches a foot or more in diameter.

PUFF-BIRD, the name first given, according to W. Swainson (Zool. Illustrations, 1st series, vol. ii., text to pl. 99), by English residents in Brazil to a group of birds now placed in the sub-family Bucoinae, which with the Galbulinae or jacamars form
PUFFIN—PUGACHEV

the family Galbulidae of Coraciiform birds standing between the trogons (q.v.) and barbets, for a long time confounded, under the general name of barbets, with the Capitonidae of modern systematists. Each group has formed the subject of an elaborate monograph—the Capitonidae being treated by C. H. T. and G. F. L. Marshall (London, 1870-1871), and the Buccinidae by P. L. Sclater (London, 1879-1882). The Buccinidae are zygodactylous birds confined to the neotropical region, in the middle parts of which, and especially in its sub-Andean sub-region, they are, as regards species, abundant; while only two seem to reach Guatemala and but one Paraguay. As with most South American birds, the habits and natural history of the Buccinidae have been but little studied, and of only one species, which happens to belong to a rather abnormal genus, has the nidification been described. This is the Chilidoptera tenobrosa, which is said to breed in holes in banks, and to lay white eggs much like those of the kingfisher and consequently those of the jacamars. From his own observation Swainson writes (loc. cit.) that puff-birds are very grotesque in appearance. They will sit nearly motionless for hours on the dead bough of a tree, and while so sitting “the disproportionate size of the head is rendered more conspicuous by the bird raising its feathers so as to appear not unlike a puff-ball... When frightened their form is suddenly changed by the feathers lying quite flat.” They are very confiding birds and will often station themselves a few yards only from a window. The Buccinidae almost without exception are very plainly-coloured, and the majority have a spotted or mottled plumage suggestive of immaturity. The first puff-bird known to Europeans seems to have been that described by G. de L. Marcgrav, under the name of “tamata,” by which it is said to have been called in Brazil, and there is good reason to think that his description and figure—the last, comic as it is in outline and expression, having been copied by F. Willughby and many of the older authors—apply to the Bucco maculatus of modern orthodoxy—a bird placed by M. J. Brisson (Ornithologie, iv. 524) among the kingfishers. But if so, Marcgrav described and figured the same species twice, since his “Matuui” is also Brisson’s “Martin-pescheur tacheté du Brésil.”

P. L. Sclater divides the family into 7 genera, of which Bucco is the largest and contains 20 species. The others are Malacoptila and Monacha, each with 7, Nonnula with 5, Chelodiptera with 2, and Micromonacha and Hotapalotata with 1 species each. The most showy puff-birds are those of the genus Monacha, with an inky-black plumage, usually diversified by white about the head, and a red or yellow bill. The English name of a sea-bird, the Fratercula arctica of most ornithologists, known however on various parts of the British coast as the bottleneke, coilteneh, pope, sea-parrot and tammy-norie, to say nothing of other still more local designations, some (as marrot and willock) shared also with allied species of Alcidae, to which family it belongs. Of old time puffins were a valuable commodity to the owners of their breeding-places, for the young were taken from the holes in which they were hatched, and “being exceeding fat,” as Carew wrote in 1602 (Surrey of Cornwall, fol. 33), “were kept salted, and reputed for fish, as coming nearest thereto in their taste.” In 1345, according to a document from which an extract is given in Heath’s Islands of Scilly (p. 100), those islands were held of the Crown at a yearly rent of 300 puffins or 6s. 8d., being one-sixth of their estimated annual value. A few years later (1464), either through the birds having grown scarcer or money dearer, the rent was doubled (op. cit. p. 196) to have been 1

There cannot be much doubt that the same puffin given to these young birds, salted and dried, was applied on account of their downy clothing, for an English informant of Gesner’s described one to him (Hist. avium, p. 110) as wanting true feathers, and being covered only with a sort of woolly black plumage. It is right, however, to state that Catesby expressly declares (Rarior. animal. Wiribus, fol. 21) that the name is derived “a naturali voc pupin. Skeat states that this is a diminutive, which favours the view that it was originally used as a name for these young birds. The parents were probably known by one or other of their many local appellations.

It is stated by both Gesner and Caius that they were allowed to be eaten in Lent. Ligon, who in 1673 published a History of the Island of Barbadoes, speaks (p. 37) of the ill taste of puffins “which we have from the isles of Scilly,” and adds “this kind of food is only for servants.” Puffins used to resort in vast numbers to certain stations on the coast, and are still plentiful on some, reaching them in spring with remarkable punctuality on a certain day, which naturally varies with the locality, and after passing the summer there leaving their homes with similar precision. They differ from most other Alcidae in laying their single egg (which is white with a few grey markings when first produced, but speedily begrimed by the soil) in a shallow burrow, which they either dig for themselves or appropriate from a rabbit, for on most of their haunts rabbits have been introduced. Their plumage is of a glossy black above—the cheeks grey, encircled by a black band—and pure white beneath; their feet are of a bright red or orange, but the most remarkable feature of these birds, and one that gives them a very comical expression, is their huge bill. This is very deep and laterally flattened, so as indeed to resemble a couler, as one of the bird’s common names expresses; but moreover it is parti-coloured—blue, yellow and red—curiously grooved and still more curiously embossed in places, that is to say during the breeding season, when the birds are most frequently seen. But it had long been known to some observers that such puffins as occasionally occur in winter (most often washed up on the shore and dead) presented a beak very different in shape and size, and to account for the difference was a standing puzzle. Many years ago Bingley (North Wales, i. 354) stated that puffins “are said to change their bills annually.” The remark seems to have been generally overlooked; but it has proved to be very near the truth, for after investigations carefully pursued during some years by Dr Bureau of Nantes he was in 1877 enabled to show (Bull. Soc. Zool. France, ii. 377-399) that the puffin’s bill undergoes what may be called an annual moult, of some of its most remarkable appendages, as well as certain horny outgrowths above and beneath the eyes, dropping off at the end of the breeding season, and being reproduced the following year. Not long after the same naturalist announced (op. cit.) iv. 1-68 that he had followed the similar changes which he found to take place, not only in other species of puffins, as the Fratercula corniculata and F. cirrhata of the Northern Pacific, but in several birds of the kindred genera Ceratohina and Simorhynchus inhabiting the same waters. The name puffin has also been given in books to one of the shearwaters which belong to the sub-family Procellariidae of the Petrels (q.v.), and Carlsberg Puffin was present at the siege of Copenhagen. He led for the next few years a wandering life; was more than once arrested and imprisoned as a deserter; and finally, after frequenting the monasteries of the “Old Believers,” who exercised considerable influence over him, suddenly proclaimed himself (1773) to be Peter III. The story of Pugachev’s strong resemblance to the murdered emperor is a later legend. Pugachev dubbed himself Peter III, the better to attract to his standard all those (and they were many) who attributed their misery to

See Zoologist for 1878, pp. 233-240.
the government of Catherine II., for Peter III. was generally remembered as the determined opponent of Catherine. As a matter of fact Pugachev and his followers were hostile to every form of settled government. The one thought of the destitute thousands who joined the new Peter was to sweep away utterly the intolerably oppressive upper-classes. Pugachev's story was that he and his principal adherents had escaped from the clutches of Catherine, and were resolved to redress the grievances of the people, give absolute liberty to the Cossacks, and put Catherine herself away in a monastery. He held a sort of mimic court at which one Cossack impersonated Nikita Panin, another Zachary Chernuishev, and so on. The Russian government at first made light of the rising. At the beginning of October 1773 it was simply regarded as a nuisance, and 500 roubles was considered a sufficient reward for the head of the troublesome Cossack. At the end of November 28,000 roubles were promised to whomever should bring him in alive or dead. Even then, however, Catherine, in her correspondence with Voltaire, affected to treat "Pafaill le Marquis de Pugachev" as a mere joke, but by the beginning of 1774 the joke had developed into a very serious danger. All the forts on the Volga and Ural were now in the hands of the rebels; the Bashkirs had joined them; and the governor of Moscow reported great restlessness among the population of central Russia. Shortly afterwards Pugachev captured Kazan, reduced most of the churches and monasteries there to ashes, and massacred all who refused to join him. General Peter Panin, the conqueror of Bender, was thereupon sent against the rebels with a large army, but difficulty of transport, lack of discipline, and the gross insubordination of his ill-paid soldiers paralysed all his efforts for months, while the innumerable and ubiquitous bands of Pugachev were in nearly every engagement. Not till August 1774 did General Mikhailov inflict a crushing defeat upon the rebels near Tarsinsy, where they lost ten thousand in killed and prisoners. Panin's savage reprisals, after the capture of Penza, completed their discomfiture. Pugachev was delivered up by his own Cossacks on attempting to fly to the Ural (Sept. 14), and was executed at Moscow on the 11th of January 1775.

See N. Dubrovkin, Pugachev and his Associates (Russ. Petersburg, 1884); Catherine II., Political Correspondence (Russ. Fr. Ger.; Petersburg, 1885, &c.); S. I. Grudzich, Emilian Pugachev (Russ.; Petersburg, 1902). (R. N. B.)

PUGET, PIERRE (1622-1694). French painter, sculptor, architect and engineer, was born at Marseilles on the 31st of October 1622. At the age of fourteen he carved the ornaments of the galleries built in the port of his native city for the decoration and construction of a ship were entrusted to him. Soon after he went to Italy on foot, and was well received at Rome by Pietro di Cortona, who employed him on the ceilings of the Barberini Palace and on those of the Pitti at Florence. In 1643 he returned to Marseilles, where he painted portraits and carved the colossal figure-heads of men-of-war. After a second journey to Italy in 1646 he painted also a great number of pictures for Aix, Toulon, Cuers and La Ciotat, and sculptured a large marble group of the Virgin and Child for the church of Lorgues. His caricatures for the balcony of the Hôtel de Ville of Toulon were executed between 1655 and 1657. N. Pouquet employed Puget to sculpture a Hercules for his château in Vaux. The artist's desire to paint gradually subsided before his passion for sculpture, and a serious illness in 1665 brought Puget a prohibition from the doctors which caused him wholly to put aside the brush. The fall of Pouquet in 1666 found Puget at Genoa. Here he executed for Sublet des Noyers his French Hercules (Louvre), the statues of St. Sebastian and of Alexandre Sauli in the church of Carignano (c. 1664), and much other work. The Doria family gave him a church to build; the senate proposed that he should paint their council chamber. But Colbert bade Puget return to France, and in 1669 he again took up his old work in the dockyards of Toulon. The arsenal which he had there undertaken to construct under the orders of the duke of Beaufort was destroyed by fire, and Puget, disheartened, took leave of Toulon. In 1685 he went back to Marseilles, where he continued the long series of works of sculpture on which he had been employed by Colbert. His statue of Milo (Louvre) had been completed in 1682, Perseus and Andromeda (Louvre) in 1684; and Alexander and Diogenes (bas-relief, Louvre) in 1685, but, in spite of the personal favour which he enjoyed, Puget, on coming to Paris in 1688 to push forward the execution of an equestrian statue of Louis XIV., found courts intrigues too much for him. He was forced to abandon his project and retire to Marseilles, where he remained till his death on the 2nd of December 1694. His last work, a bas-relief of the Plague of Milan, which remained unfinished, was placed in the council chamber of the town hall of his native city.

In spite of Puget's visits to Paris and Rome his work never lost its local character: his Hercules is fresh from the galleries of Toulon; his saints and virgins are men and women who speak Provençal. His best work, the St. Sebastian at Genoa, though a little heavy in parts, shows admirable energy and life, as well as great skill in contrasting the decorative accessories with the simple surface of the nude. There is in the museum of Aix in Provence the bust of a long-haired young man in pseudo-classical costume which is believed to be a portrait of Louis XIV. made by Puget at the time of the king's visit in 1660. See Léon Lagrange, Pierre Puget (Paris, 1868, with a catalogue of works); Charles Ginoux, Annales de la vie de P. Puget (Paris, 1894); Philippe Auquier, Pierre Puget ... biographie critique (Paris, 1903).

PUGILISM (from Lat. pugil, boxer, Gr. pugix, with clenched fist), the practice or sport of fighting with the fists. The first mention of such fighting in literature is found in the 23rd book of the Iliad, and shows that in Homer's time the art was already highly developed. The occasion was the games at the funeral of Patroclus, the champions engaged being Eteocles, the elder brother of the wooden horse, and Euryalus. Each combatant seems to have been naked except for a belt, and to have worn the cestus. The fight ends with the defeat of Euryalus. According to Virgil (Aeneid, vi.) similar games took place within the walls of Troy at the funeral of Hector, the principal boxers being Dares, the winner, and the gigantic Butex, a pupil of Ancyus, Paris, the Trojan champion, abstaining from the contests. Further on we find the account of the games on the occasion of the funeral of Anchises, in the course of which Dares, the Trojan, receiving no answer to his challenge from the Sicilians, who stood aghast at his mighty proportions, claims the prize; but, just as it is about to be awarded him, Eutellos, an aged but huge and sinewy Sicilian, arises and casts into the arena as a present to the victor, and all are rewarded with blood and brains, which he has inherited from King Euryx, his master in the art of boxing. The Trojans are now appalled in their turn, and Dares, aghast at the fearful implements, refused the battle, which, however, is at length begun after Aeneas has furnished the heroes with equally matched cesti. For some time the young and lusty Dares circles about his gigantic but old and stiff opponent, upon whom he rains a torrent of blows which are avoided by the clever guarding and dodging of the Sicilian hero. At last Eutellos, having got his opponent into a favourable position, raises his tremendous right hand on high and aims a terrible blow at the Trojan's head; but the wary Dares deftly steps aside, and Eutellos, missing his adversary altogether, falls headlong by the impetus of his own blow, with a crash like that of a falling pine. Shouts of mingled exultation and dismay break from the multitude, and the friends of the aged Sicilian rush forward to raise their fallen champion and bear him from the arena; but, greatly to the astonishment of all, Eutellos motions them away and returns to the fight more keenly than before. The old man's blood is stirred, and he attacks his youthful enemy with such furious and headlong rushes, buffeting him grievously with both hands, that Aeneas puts an end to the battle, though barely in time to save the discomfited Trojan from being beaten into insensibility.

Although fist-fighting was supposed to have been a feature of the mythological games at Olympia, it was not actually introduced into the historical
Olympic contests until the 23rd Olympiad after the re-establishment of the famous games by Iphitus (about 880 B.C.). Onomastos was the first Olympic victor. In heroic times the boxers are supposed to have worn the Ἠώς, or belt, but in the Greek games the contestants, except for the cestus, fought entirely naked, since the custom had been introduced in the 15th Olympiad, and was copied by the contestants at the Pythian, Nemean, Isthmian and Panathenaic games (see GAMES, CLASSICAL). At Olympia the boxers were rubbed with oil to make them supple and limit the flow of perspiration, a precaution the more necessary as the Olympic games were held during the hottest part of the year. The cesti, of which there were several varieties, were bound on the boxers’ hands and wrists by attendants or teachers acting as seconds. On account of the weight of the gloves worn, the style of boxing differed from that now in vogue (see BOXING), the modern straight-from-the-shoulder blow having been little used. Both Homer and Virgil speak of “falling blows,” and this was the common method of attack, consisting more in swinging and hammering than in punching. The statue of a Greek boxer in the Louvre shows the right foot forward, the left hand raised as if to ward off a blow from above, and the right hand held opposite the breast, the whole attitude more resembling that of a warrior with sword and shield than of a modern boxer. The pugilists of Rome, who were in many cases Greeks and employed Greek methods, exaggerated the brutality of the fist-fight to please the Roman taste, and the sanguinary contest between Dares and Entellus, described above, although in some respects an anachronism as an account of a pugilistic battle in primitive times, was doubtless an exact portrayal of the encounters to be seen in Virgil’s day in the circuses of Rome. Nevertheless it must not be understood that the boxing matches at the Greek games were not themselves severe to the point of brutality, in spite of the fact that style and grace of movement were sedulously taught by the masters of the time. The Greek champions trained for months before the games, but encounters between athletes armed with such terrible weapons as the loaded cestus were bound to result in very serious bruises and even disfigurement. Pluck was as highly thought of as at the present day, and it was related of a certain Eurydamas that, when his teeth were battered in, he swallowed them rather than show that he was hurt, whereas his antagonist, in despair at seeing his most furious blows devoid of effect, gave up the battle. As, on account of the swinging style of blows, the ears were particularly liable to injury ear-protectors (ἀσχημορίδες) were generally used in practice, though not in serious combats. The so-called “pancratist’s ear,” swollen and mis-shapen, was a characteristic feature of the Greek boxer. The satirists of the time flung their grim jests at the champion bruisers. Lucilius writing of a Greek boxer of Etruria (Anthologia epigrammatum graecorum), says, “Aulos, the pugilist, condescends to the God of Pisa all the bones of his cranium, gathering up one by one. Let him but return alive from the Nemean Games, O mighty Jupiter, and he shall suffer the without doubt, the vertebrae of his neck, which is all he has left!”

The rules of Greek boxing were strict. No wrestling, grappling, kicking nor biting were allowed, and the contest ended when one combatant owned himself beaten. On this account pugilism and the *pancratium* (see below) were forbidden by Lycurgus, lest the Spartans should become accustomed to an acknowledgment of defeat (Plutarch, Lycurgus). In spite of the terrible injuries which often resulted from these contests it was strictly forbidden to kill an adversary, on pain of losing the prize. Rhodes, Aegina, Arcadia and Elis produced most of the Olympic victors in boxing, which was considered as an excellent training for war. According to Lucan (Anaeh. 3) Solon recommended it for pedagogic purposes, and the contest with the *sphairei*, or studded cesti, was added by Plato to his list of warlike exercises as being the nearest approach to actual battle.

The Greek athletic contest called *pancratium* (πανκρατος, complete, or all-round, contest) was introduced into the Olympic games in the 38th Olympiad, was a combination of boxing and wrestling in which the contestants, who fought naked, not wearing even the cestus, were allowed to employ any means except biting to wring from each other the acknowledgment of defeat. Boxing, wrestling, kicking, dislocation of joints, breaking of bones, pulling of hair and strangling were freely indulged in. The fight began with sparring for openings and was continued on the ground when the contestants fell. Many pancratists excelled in obtaining quick holds of their opponents’ fingers, which they crushed and dislocated so completely that all effective opposition ceased. Sudden attacks resulting in the dislocation of an arm or leg were also taught, reminding one of the Japanese jiu-jitsu. The *pancratium* was considered by the Greeks the greatest of all athletic contests and, needless to say, only the most powerful athletes attempted it. It became popular in Rome during the Empire and remained so until the time of Justinian.

Diagoras of Rhodes, his three sons and many grandsons, who were sung by Pindar (Olymp. 7), were the most celebrated of the Olympic boxing champions. One of the sons, Dorieus, was three times victorious at Olympia in the *pancratium*, and during his career won eight Olympian, eight Isthmian, seven Nemean and one of the Pythian prizes. Many famous champions also came from the Greek colonies, like the Locrian Euthymus, who conquered three times at Olympia. Another celebrated fighter and wrestler was Milo of Crotona (520 B.C.).

Boxing was evidently in vogue in very ancient times in Italy, imported, in all probability, from Greece, for Livy (i. 35) relates that, at the first celebration of the great Roman games (ludi, romani magnique varie appetiti) by Tarquinii Priscus (6th century B.C.), boxers were brought from outlying provinces; and there was an old tradition that a school of pugilism flourished in Etruria in heroic times. During the republic boxing was cultivated as a gentlemanly exercise, and we find Cato the Elder giving his son instruction in the art (Plutarch, Cale Major). Tacitus (Ann. xvi. 3) says that the emperor Caligula imported the best Campanian and African pugilists for the gladiatorial games, and Strabo (ii. 3) records that the Lusitanians and also the Indians, who gave virgins as prizes, boxed. The art remained popular in Italy down to a late period of the Empire.

From the fall of the Roman Empire to the beginning of the 19th century pugilism seems to have been unknown among civilized nations with the single exception of the English.

The first references to boxing in England as a regular sport occur towards the end of the 17th century, but little mention is made of it before the time of George I., when “prize-fighters” engaged in public encounters for money, with the backsword, falchion, foil, quarter-staff and single-stick, and, to a less extent, with bare fists, the last gradually gaining in popularity with the decline of fencing. The most celebrated of these fighters and the one who is generally considered to have been the first champion of England, fighting with the bare fists, was James Figg, who was supreme from 1719 to 1730. Figg was succeeded by Captain Cribb, both of whom made way in 1734 for Jack Broughton, who built the amphitheatre for public displays near Tottenham Court Road and who was undisputed champion until 1750. Broughton seems to have been a man of intelligence, and to him is ascribed the scientific development of the art of boxing. During his time the sport became truly national and the prize-fighter the companion of the greatest in the land. Among Broughton’s successors were Slack, “Big Ben” Brain, Daniel Mendoza (a Jew who flourished about 1790 and was the proprietor of the Lyceum in the Strand), J. Jackson, Tom Cribb, Jem Belcher, Pearce (called the “Game Chicken”), and John Gully, who afterwards represented Pontefract in Parliament.

To Broughton is ascribed the invention of boxing-gloves for use in practice. All prize-fights, however, took place with bare knuckles in roped-off spaces called rings, usually in the open air. Pugilists toughened their hands by “picking” them in a powerful astringent solution. A fight ended when one
of the "bruisers," as they were called, was unable to "come to the scratch," i.e. the middle of the ring, at the call of the referee at the beginning of a new round. Each round ended when one fighter fell or was knocked or thrown to the ground, but a pugilist "going down to avoid punishment," i.e. without being struck by the opponent, was liable to forfeit the fight. Wrestling played an important rôle in the old prize-ring, and a favourite method of weakening an adversary was to throw him heavily and then fall upon him, seemingly by accident, as the manoeuvre, if done intentionally, was foul. The fighting was of the roughest description, low tricks of all kinds being practised when the referee's attention was diverted, gouging out an adversary's eye being by no means unknown. Until 1793 pugilists wore long hair, but during a fight in that year Jackson caught Mendoza by his long locks and held him down helpless while he hit him. This was adjudged fair by the referee, with the result that prize-fighters have ever since cropped their head. Nevertheless there were rules which no fighter dared to overstep, such as those against kicking, hitting below the belt, and striking a man when he had fallen.

From the time of Cribb the English champions were Tom Spring (1824), Jem Ward (1825), Jem Burke (1833), W. Thompson, called "Bendigo" (1830-1845), Ben Caunt (1841), W. Perry, the "Tipton Slasher" (1850), Harry Broome (1851), Tom Sayers (1857-1860), Jem Mace (1861-1863), Tom King (1863), and again Mace, until 1872.

In America boxing began to be popular about the beginning of the 19th century. The first recognized national champion was Tom Hyer (1841-1848), who was followed by James Ambrose (born in Ireland), called "Yankee Sullivan;" John Morrissey (afterwards elected to the United States Congress); John C. Heenan; Tom Allen (of England); Jem Mace (of England); J. Kilrain; John L. Sullivan (1880-1881); J. J. Corbett (1862-1897); Robert Fitzsimmons (1867-1900) (born in Cornwall); James J. Jeffries. The defeat of the last named by the negro Jack Johnson in 1910 caused a great sensation.

What is still the most celebrated prize-fight of modern times took place at Farnborough in April 1860, between Tom Sayers and the huge youthful American pugilist J. C. Heenan, the "Benicia Boy," who had been defeated in America by Morrissey, but had succeeded to the championship upon the latter's retirement. The English champion was a much smaller and lighter man than his challenger, a fact which increased the popular interest in the fight. Although the local English authorities endeavoured to prevent it taking place, Heenan, complaining that he had "been chased out of eight counties," the ring at Farnborough was surrounded by a company containing representatives of the highest classes, and the exaggerated statement was made that "Parliament had been emptied to patronize a prize-fight." The battle lasted for 2 hours and 20 minutes, during which Heenan, owing to his superior weight and reach, seemed to have the advantage, although nearly blinded by Sayers' hard straight punches. During one of the opening rounds a tendon in Sayers' right ring finger was cut, and in the 10th round he sustained a cut in the face. In the 12th round Heenan was thrown and fallen, but was able to rise. Heenan was knocked down twice in the 15th round, and Sayers was knocked down once in the 19th, but the fight continued. The battle ended with a decision of "no decision," as neither man was able to gain the decision of the referee, or was able to "count out" the opponent. The decision was reversed on appeal, and Sayers was awarded the prize. The fight was considered by many to be the greatest in the history of prize-fighting, and it is recorded that the American pugilist was unable to "count out" his opponent, and that Heenan was "bothered," i.e. druged, and this lack of fairplay, added to the brutality of fist-fights, gave the death-blow to pugilism of the old kind. In its place came fighting and boxing with padded gloves, small ones weighing about 4 oz. being used by professionals, while amateurs, who boxed and spurred rather than fought (see BOXING), made use of larger and softer gloves.

An added impetus was given to boxing as well as pugilism in 1866 by the founding of the "Amateur Athletic Club" by John C. Chambers, who, assisted by the marquess of Queensberry, drew up the code of rules for competitions still in vogue and called after that nobleman, who, in 1867, presented cups for the amateur championships at the different weights. These rules prohibit all rough and unfair fighting, as well as wrestling, and divide a match into rounds of three (or two) minutes each, with half a minute rest between the rounds. It is a matter of agreement in professional battles whether in "breaking away" after a clinch blows may be struck or not. When a contestant is knocked down (a man on one knee is technically down) he is allowed ten seconds, usually counted aloud by the referee, in which to rise and renew the fight. Should he be unable to do so he is "counted out" and loses the match.

See FISTIANA (London, 1868); American FISTIANA (New York, 1876); Egan, Boxiana (London, 1818-1824); PUNION, BOXING, and Wrestling, in the Badminton Library (London, 1889); R. G. A. Winc, Boxing, lsthmanian Library (London, 1897).

PUGIN, AUGUSTUS WELBY NORTHMORE (1812-1852), English architect, son of Augustus Charles Pugin (1762-1832), a Frenchman by birth who settled in London as an architectural draughtsman and had several pupils who rose to fame, was born in Store Street, Bedford Square, on the 1st of March 1812. After an education at Christ's Hospital he entered his father's office, where he displayed a remarkable talent for drawing. His father was for many years engaged in preparing a large series of works on the Gothic buildings of England, almost, if not quite, the first illustrated with accurate drawings of medieval buildings; and the son's early youth was mostly occupied in making minute measured drawings for these books. In this way his enthusiasm for Gothic art was first aroused. All through his life, both in England and during many visits to Germany and France, he continued to make great numbers of drawings and sketches, in pen and ink or with sepia monochrome, perfect in their delicacy and precision of touch, and masterpieces of skilful treatment of light and shade. At first he acted as assistant in his father's work, and his own independent efforts to obtain business were not very successful. In 1837 he was employed to design furniture in a medieval style for Windsor Castle; and in 1831—the year he married his first wife, Ann Garnett, who died in childbirth a year later—he designed scenery for the new opera of Kenilworth at Her Majesty's theatre. But he got into money difficulties, and soon after his marriage he was imprisoned for debt. When he came out again incurred serious losses over an attempt to start a shop for supplying architectural accessories of his own designing, which he had to give up. But after his second marriage in 1833 to Louisa Burton (d. 1844), and his reception into the Roman Catholic Church shortly afterwards, he began to obtain more steady architectural practice and by degrees he acquired the reputation which has made his name stand foremost among those responsible for the English Gothic revival (see ARCHITECTURE: "The Gothic Revival"). No man had so thoroughly mastered the principles of the Gothic style in its various stages, both in its leading lines and in the minutest details of its mouldings and carved enrichments. In 1837–1843 he assisted Charles Barry by working out the details of the designs for the new Houses of Parliament at Westminster; and though his exact share in the designs was subsequently the subject of bitter controversy after both he and Barry were dead, there is no doubt that, while he was working as Barry's paid clerk, a great deal in the excellence of the details was due to him and to his training of the masons and carvers. His conversion to Roman Catholicism, while part and parcel of his
devotion to Gothic art, naturally brought him employment as an architect mainly from Roman Catholics; and many of his executed works suffered from the fact that his designs were not fully carried out, owing to a desire to save money or to spend it so as to make the greatest possible display. For this reason his genius is often more fairly displayed by his drawings than by the buildings themselves. In almost every case his design was seriously injured, both by cutting down its carefully considered proportions and by introducing shams (above all things hateful to Pugin), such as plaster groining and even cast-iron carving. The cathedral of St George at Southwark, and even the church in Farm Street, Berkeley Square, London, are melancholy instances of this. Thus his life was a series of disappointments; no pecuniary success compensated him for the destruction of his best designs, as in him the man of business was thoroughly subordinate to the artist. He himself used to say that the only church he had ever executed with unalloyed satisfaction was the one at Ramsgate, which he not only designed but paid for. Pugin was very broad in his love for the medieval styles, but on the whole preferred what is really the most suited to modern requirements, namely the Perpendicular style of the 15th century, and this he employed in his simpler domes and spires. Much of this was in his own house at Ramsgate and in the stately Adare Hall in Ireland built for Lord Dunraven. The cathedral of Killarney and the chapel of the Benedictine monastery of Douai were perhaps the ecclesiastical buildings which were carried out with least deviation from Pugin's original conception.

Apart from his work as an architect, his life presents little of detail to record. In 1836 he published his Contrasts; or a Parallel between the Architecture of the 15th and 19th centuries, in which he seriously criticized the architecture of Protestantism. His other principal publications were True Principles of Christian Architecture (1841); Glossary of Ecclesiastical Ornament (1844); and Treatise on Chancel Screens and Rood Lofts (1851). He was a skilful etcher, and illustrated in this way a number of his works, which were written with much eloquence, great antiquarian knowledge and considerable humour. This last gift is exemplified in a series of etched plates in his Contrasts; on one side is some noble structure of the middle ages, and on the other an example of the same building as erected in the 19th century. In 1849 he married a third time, daughter of Thomas Knill. Early in 1852 he was attacked by insanity, and he died on the 14th of September that year. His eldest son by his second wife, Edward Welby Pugin (1834-1875), was also an accomplished architect, who carried on his father's work.

See B. Ferrez, Recollections of A. W. Pugin and his Father (London, 1861).

**PUISNE** (from O. Fr. *puisné*, modern *puisin*, later born, inferior; Lat. *postea*, afterwards, and *natus*, born), a term in law meaning "inferior in rank." It is pronounced "puny," and the word, so spelt, has become an ordinary adjective meaning weak or undervized. The judges and barons of the common law courts at Westminster, other than those having a distinct title, were called *puisne*. By the Supreme Court of Judicature Act 1877, a "puisne judge" is defined as a judge of the High Court other than the lord chancellor, the lord chief justice of England, the master of the rolls, the lord chief justice of the common pleas, and the lord chief baron, and their successors respectively.

**PUJAH** or *Pooja*, the Hindu ceremonies in idol-worship. Colloquially the word has come to be applied by Anglo-Indians to any kind of rite; thus "pujah of the flag" is the sepyo term for skating of the colours.

**PUKET** (also known by the Chinese name *Tongkah*), the first Siamese port on the west coast of the Malay Peninsula, situated on the eastern side of the island of Junk Ceylon (Malay, "Ujong Salang") in 4° 50' N. and 98° 24' E. It is the headquarters of the high commissioner of the Siamese administrative division of the same name, and has a population of about 30,000, of which more than a third is Chinese. Beneath the town and around it lie deposits of tin ore which have been worked by Chinese from ancient times, and the extraction of which still furnishes occupation for the majority of the inhabitants. In 1907, dredging for tin in the harbour was undertaken by a European company. Puket has been a resort of European merchants since the 16th century. During the ancient wars between Siam and Burma it was more than once attacked by the latter, but was relieved by forces from Nakhon Sri Tammarat (Ligore) on the mainland. The Siamese mining department has a branch at Puket under control of European officers.

**PULASKI, CASIMIR**, Count (1748-1779), Polish soldier, was born in Podolia in 1748, and took a prominent share, under his father Count Joseph Pulaski, in the formation of the confederation of Bar and in the military operations which followed, becoming ultimately commander-in-chief of the Polish patriot forces. Driven into exile about 1772, Pulaski went to America and joined the army of Washington in 1777. He distinguished himself at once in the battle of Brandywine, was made a brigadier-general and chief of cavalry by Congress, and fought at Germantown, and in the battles of the winter 1777-78, after which he raised a mixed corps called the Pulaski legion. At the head of this force he won further distinction in the southern theatre of war, and successfully defended Charleston in May 1779. He was mortally wounded in the unsuccessful attack on Savannah (Oct. 9) and died two days later on board ship. Congress voted a monument to his memory; and though this vote has never been carried into execution, Lafayetted laid the cornerstone of a monument in Savannah in 1824, and this was completed in 1855.

**PULCI, LUIGI** (1431-1487), Italian poet, was born at Florence, of a well-connected family. His elder brother Luca (d. 1470) was also a poet, author of *Pistole, Dridiade d'amore,* and *Cirifio Calvano.* Luigi was patronized by Cosimo, Piero, and Lorenzo de' Medici, and was the author of various works in poetry and prose. He is famous, however, as the first to bring artistic romance into Italian literature in his heroic poem *Morgante Maggiore* (Venice, 1481), an epic of a giant converted to Christianity, who accompanies Orlando (Roland). *(See Italian Literature.)*

**PULGAR, HERNANDO DE** (1436-1492), Spanish prose-writer, was born at Pulgar (near Toledo) in 1436 and was educated at the court of John II. Henry IV. made him one of his secretaries, and under Isabella's husband, first as to other, and finally as historiographer-royal. He is said to have died in 1492. His *Crónica de los Reyes Católicos*, wrongly ascribed in the first edition (1565) to Antonio de Lebrija, is often inaccurate and always obsequious; but the record is not without value as regards events within the author's personal experience. Pulgar's *Claro Vares de Castilla* (1486), an account of celebrities at the court of Henry IV., is interesting in matter and style. He compiled a commentary (1487?) on the *Coplas de Mingo Revufo*. His *Letters*, written to various persons of eminence, were first published in 1485-1486.

**PULICAT**, a town of British India, in Chingleput district, Madras, 23 m. N. of Madras city. Pop. (1901), 5448. The Dutch built a fort here as early as 1669, and it was for a long time their chief settlement on the Coromandel coast. Repeatedly captured, it did not finally become British until 1825. It gives its name to the Pulicat lake, a shallow lagoon stretching for about 37 m. along the coast. The seaward side is formed by the island of Sririhot, which supplies firewood to Madras city.

**PULKOVO** or *Pulkovskoye*, or Pulkovskoye, in the government of St Petersburg, 10 m. S. of the city of St Petersburg. Pop. 2000. It contains the Pulkovo observatory, on a hill 248 ft. high, in 59° 46' 18" N. and 30° 10' 40" E. It was built in 1833-1839.

**PULLEY**, a wheel, either fixed to a turning axle or carried freely on a stationary one, the periphery of which is adapted to receive some form of wrapping connector. A pulley carried on a rotating shaft and connected to another pulley on a second shaft by an endless band consisting of a flat belt, rope, chain or similar connector serves for the transmission of power from the one shaft to the other and is known as a driving pulley;
while combinations of pulleys or "sheaves," mounted in fixed or movable frames or "blocks," constitute mechanisms used to facilitate the raising of heavy weights. The word appears in Mid. Eng. as pulley or polley (late), also as poleyn (Prompt. Parl.). The first forms seem to be from the O. Fr. poulii, which itself is regarded as coming from the O. Eng. pulken, to pull. The Low Lat. forms polea, polegia, whence Span. polea and Ital. polegia, are apparently from the Fr. poulii. The earliest form, poleyn, is represented in Fr. by poulain, literally a col, Low Lat. pulianus, pulius, the young of any animal, the root of which is seen in English "foal." Poulain was used of a rope to let casks down into a cellar or to raise heavy weights. The use of the name of an animal for a mechanical device is not uncommon, cf. "crane," or "easel," from Du. ezel, literally "little ass."

**Driving pulleys** are usually constructed of cast iron, and are of circular form, having a central navel by which they are secured to the shaft by keys or other fastenings, and straight or curved arms connecting the nave to the rim, which latter is of a form adapted to the connector. Pulleys are usually cast in one piece, and the proportions of the various parts are designed to resist the unknown stresses due to contraction of the casting in cooling, in addition to the stresses to which pulleys are subjected in use. The rim is slightly wider than the belt, and is of such a section as will suffice to resist the stress due to the pull of the belt, which is commonly taken as 80 lb per inch of width for single belting and 140 lb per inch of width for double belting. The rim is also subject to a centrifugal tension of amount \(\frac{wv^2}{2g}\) pounds per square inch of section, where \(w\) is the weight in pounds of a length of one foot of the pulley rim one square inch in section, and \(v\) is the velocity of the rim in feet per second. This stress amounts to 1043 lb per square inch, if the velocity is 100 ft per second. The combination of these stresses, and when in the rim velocity of cast-iron pulleys to 80 or 100 ft per second. The dimensions of the navel depend to a large extent on the method of keying or otherwise securing the pulley to the shaft. The number of the arms is arbitrary, and they may be curved to diminish the liability to fracture from contraction in the cooling of the cast iron, but in other respects are preferably straight, since they are then lighter and stronger. The arms are elliptical in cross-section, diminishing from the nave to the rim, and are usually designed as equally loaded cantilevers, fixed at the nave and free at the rim. These assumptions are probably not nearly correct, and, as the stresses caused by the cooling of the casting are unknown, it is necessary to choose a low working stress of about one ton per square inch. The statistical experiments of C. H. Benjamin (American Machinist, 1868) on cast-iron pulleys loaded by a belt to imitate the conditions in practice led him to the conclusion that the rim is usually not sufficiently rigid to load the arms equally, and that the ends of the arms are subjected to bending movements of opposite sign, that at the nave being almost invariably the greater.

Pulleys are also built up of wrought iron and steel, and can then be constructed entirely free from internal stress; they are thus much lighter and stronger, and are not liable to fly to pieces like cast iron if they break. Fig. 1 shows a built-up pulley having a cast-iron nave A, straight wrought-iron arms B, screwed therein and connected to a steel plate-rim C by riveted ends, and also by screwed flanges D riveted on each side to the rim. The pulley is in halves to facilitate forming, and when in the rim sections C are joined by plates E, bolted or riveted to the rim. The two halves of the nave are secured by bolts or rivets passing through the flanges F, and the pulley is connected to the shaft by a sunk key or by conical keys driven in between the shaft and the boss, which latter is bored to suit. A modified form of this arrangement of cone keys is shown in the figure, in which a screwed conical bush M, divided into several parts longitudinally, is clamped round the shaft, and screwed into the corresponding part of the nave until the grip is sufficient. The parts of the bush are glued to a sheet of emery paper, so that its rough side may give a better grip on the shaft.

Pulleys are also made of paper, wood, and other materials. Wooden pulleys are preferably made of maple, the rim being formed of small sections morticed, pinned and glued together, with the grain set in such directions that any warping of the material will leave the cylindrical form practically unaltered. Wooden pulleys are generally made in two halves, bolted together at the rim and nave, and are provided with wooden spokes dovetailed into the rim and secured by keys. The pulley is secured to the shaft by conical keys, to give a frictional grip on both the side to and the pulley; these keys may have their exterior surfaces eccentric to the shaft, with corresponding recesses in the nave, so that the pulley and keys virtually form one piece.

If the centre of gravity of a pulley is on the axis of rotation, and the whole mass is distributed so that the axis of inertia coincides with the axis of rotation, there can be no unbalanced force or unbalanced couple as the pulley revolves. The magnitude of the unbalanced force, for a mass of \(w\) pounds at a radius of \(r\) feet and a velocity of \(v\) feet per second, is expressed by \(\frac{wv^2}{2g}\); and, since the force varies as the square of the velocity, it is necessary carefully to balance a pulley running at a high speed to prevent injurious vibrations. This can be accomplished by attaching balance-weights to the pulley until it will remain stationary in all positions, when its shaft rests on two horizontal knife-edges in the same horizontal plane, or, preferably, the pulley and shaft may be supported on bearings resting on springs, and balanced by attached weights until there is an imperceptible vibration of the springs at the highest speed of rotation.

The rims of pulleys, round which flat bands are wrapped, may be truly cylindrical, in which case the belt will run differently at any part of the pulley, or the rim may be swelled towards the centre, when the central line of the band will tend to run in the diametral plane of the pulley. This self-guiding property may be explained by the tendency which a flat band has, when running upon a conical pulley in a direction normal to its axis, to describe a spiral path as it wraps on to the surface because of the lateral stiffness of the material; the advancing side therefore tends to rise towards the highest part of the cone. If two cones are placed back to back the belt tends to rise to the ridge and stay there. In practice the pulley rim is curved to a radius of from three to five times its breadth, and this not only guides the belt, but allows the line of direction of the advancing side to vary to a small extent, depending on the elasticity of the material.

Parallel shafts may be driven by flexible bands or connectors passing over pulleys, the central planes of which coincide, without any guiding arrangements for the belting. The shafts revolve in the same or opposite directions, according as the belt is open or crossed. Means of changing the relative speeds of rotation are furnished by pulleys of continuously varying diameter, or by speed cones (see Mechanics: Applied). A common arrangement for driving a lathe spindle, in either direction at several definite speeds, is to provide a countershaft on which are mounted two fixed pulleys and two loose pulleys to accommodate two driving belts from the main shaft, one of which is open and the other crossed. The belts are moved laterally by the forks of a striking gear pressing on the advancing sides of the belts, and the pulleys are arranged so that the belt when the loose pulleys, or can be shifted so that one wraps round a fixed pulley while the other still remains on its loose pulley. Motion in either direction is thereby obtained, and a considerable variation in the speed of rotation can be obtained by providing a cone pulley on the counter-shaft, which drives the cone pulley secured to the lathe.
spindle by a separate hand. The dimensions of the pulleys are generally so arranged that the return motion of the lathe spindle is faster than the forward motion. An alternative arrangement consists in providing two loose pulleys on the counter-shaft, driven by open and crossed belts respectively, and arranging two clutches on the shaft, so that by the movement of a sliding block, controlled by hand, one or other of the clutches can be put in gear.

The proportions of cone pulleys for open or crossed belts may be determined by considering the expression for the half length \( l \) of a belt wrapping round pulleys of radius \( r_1 \) and \( r_2 \) respectively, and with centres distant \( c \) apart. The value of \( l \) may be easily shown to be

\[
\frac{1}{2}(r_1 + r_2)\pi \frac{c}{\sin a} = \frac{1}{2} \frac{c}{\sin a}.
\]

The value of \( a \) is in general small, and an approximate solution may be obtained by substituting two or three terms of the expansions for \( \sin a \) and \( \cos a \). This, however, leads to a troublesome numerical solution. An accurate geometrical solution by C. Culmann gives

\[
r_1 = \frac{l}{\pi} - c (a \sin a + \cos a) - \frac{c}{2} \sin a,
\]

\[
r_2 = \frac{l}{\pi} - c (a \sin a + \cos a) + \frac{c}{2} \sin a.
\]

The value of \( a \) is generally determined by the diagram (fig. 2), and for any radius \( DE \) at an angle \( a \) and corresponding tangent \( EG \) terminated by the evolute, the perpendicular distance of \( G \) from the line \( AD \) is \( c (\cos a + a \sin a) \). If now a line is drawn from \( A \) to the bisector \( H \) of the side \( BC \), it will meet the vertical through \( G \) in \( I = c (a \sin a + \sin a) \). A circular arc, centre \( D \) and radius \( c/2 \), meets \( DE \) in \( K \), and the perpendicular KL gives \( \frac{c}{2} \sin a \). This distance is marked off from the point \( L \) in each direction, whereby the points \( M \) and \( N \) are obtained, the distance apart of which represents the value \( r_1-r_2 \). If now the value \( \frac{l}{\pi} = O \) be marked off, and a horizontal line be drawn through the point \( O \), the line OM represents \( r_1+r_2 \). Repeating this construction for all values of \( a \) between 0° and 90°, we obtain a curve BPC which can be used for determining the ratios of corresponding drums of cone pulleys or of conical drums for open belts.

The curve BPC is generally used with the ascissa spaced more conveniently for practical applications, and a modification of the diagram by J. F. Klein (Journ. Franklin Inst., vol. lxxix.) is often used instead.

When pulleys are mounted on shafts which are parallel to one another, the band will retain its position, provided that its central line advances towards each pulley in the diametral plane of the latter. This condition is fulfilled in the example shown by fig. 3, in which the central planes of each pulley pass through the points of delivery of the other pulley for the given direction of motion. If the motion is reversed the condition is no longer satisfied and the belt will leave the pulleys. In more complicated cases guide pulleys must be used. In the most general case for inclined pulleys, any two points may be chosen on the line of intersection of the diametral planes, and tangents drawn to the pitch circles of the pulleys. Guide pulleys are set with their diametral planes in the planes containing corresponding pairs of tangents, and a continuous belt wrapped round these pulleys in due order can then be run in either direction.

The rims of pulleys for hemp or other ropes or cords are grooved, and the sides are usually either inclined at 45° or curved to give a sharper angle at the outside than at the bottom of the groove; in the latter case, as the rope wears it engages in a groove of greater angle and less effective grip. Wire ropes are injured by the lateral crushing of the material, and in this case the grooves are wide enough to allow the rope to rest on the rounded bottom, which is lined with leather or wood to diminish the wear and increase the friction. In English practice there are as many separate endless ropes as there are pairs of grooves in the two pulleys to be connected, but in cases of American practice the rope is continuously wound round the two pulleys, and the free end passes over a pulley mounted on a movable weighted carriage to adjust the tension. It is of considerable importance that the effective radius of action of the rope remain constant throughout each pulley, otherwise the wear on the rope becomes very great and its life is diminished.

The grooves must be turned exactly alike, and the rope must be of the same diameter throughout to diminish slip.

Pulleys may be detachably connected to a shaft by friction clutches, so that they may be thrown in and out of engagement at will. The section, fig. 4, shows a clutch for a rope-driven pulley A, which runs freely on a bush B on the shaft, and is provided with an enlarged cylindrical nave or clutch box C. A split ring D, carried by the clutch and turning with it, can be thrust against the clutch box by right- and left-handed screws E, so that a sufficient grip is obtained to cause the clutch and the pulley to turn as one piece. The engagement of the pulley and clutch is determined by a hand-controlled block F sliding on the shaft, the movement of which is communicated to the right- and left-handed screw shafts by links G connected to the lever H.

The resistance to slipping of a flat belt on a pulley may be obtained by considering the equilibrium of a small arc of the pulley surface subtending an angle \( \theta \) at the centre, and having tensions \( T \) and \( T+\Delta T \) at its extremities. Neglecting quantities of the second order, the pressure on the pulley is \( T \theta \), and the friction is \( \mu \theta (T+\Delta T) \) where \( \mu \) is the coefficient of friction between the belt and the pulley. We have therefore \( \Delta T = \mu T \theta \). Integrating the expression for an angle of wrapping \( \theta \), we obtain the relation

\[
\log \frac{T_2}{T_1} = \Delta \theta,
\]

where \( T_1 \) and \( T_2 \) are the end tensions. For leather belts on cast-iron pulleys the value of \( \mu \) may be taken as 0.4, giving a ratio of the tensions on the tight and slack sides of \( T_1/T_2 = 3:514 \), when the angle of wrapping is 180°. For ropes in the grooves of cast-iron pulleys, where \( \phi \) is the inclination of the sides of the grooves, that is, the value of the normal pressure is increased in the ratio of \( \cosec \phi \). A usual value of \( \mu \) for hemp ropes on cast-iron pulleys is 0.3, and the exponential log ratio is therefore \( 0.3 \phi \cosec \phi \) when \( \theta = \pi \). At high speeds the centrifugal tension of the belt or rope, of amount \( wp^2 \), may be considerable, and must be subtracted from the end tensions.

**Pulley Blocks.**—Frames or blocks containing pulleys or sheaves are used in combination for lifting heavy weights. There are usually two blocks, of which one \( A \) (fig. 5) is fixed, and the other \( B \) is movable, and a rope or chain, with one end secured to one of the blocks at \( C \), passes round the sheaves in a continuous coil, leaving a free end \( D \) at which the effort is applied. In the arrangement shown there are three equal sheaves in each block, and each set turns on a pin secured in the framing. The load, supported by the lower hook, is raised by hauling on the free end and, neglecting any slight obliquity of the plies of rope, the free end moves six times as fast.
as the lower block carrying the weight, and in the absence of friction and other resistances the mechanical advantage will be in the same ratio of the effort to the resistance. In practice the full advantage of this or any other similar combination is not realized, because of the friction of the sheaves against the pin or shaft, and more important still is the stiffness of the rope, which requires work to be done upon it to bend it round the sheave and straighten it again. The effect of pin friction is equivalent to diminishing the radius of the effort and increasing that of the resistance.

For a single pulley of diameter D, turning on a fixed pin of diameter d, the relation of the effort E to the load W, where f is the coefficient of friction, is

\[ E = \frac{W}{1 - 2f/D} \]

approximately. The resistance of the rope to bending causes an additional resistance, which experiment shows can be expressed in the form \( W_R/c \), where \( c \) is a coefficient. Hence \( E = W(1 + 2f/D + c) \). As \( c \) is a coefficient of friction, it is impossible to separate its effects from those of other resistances, and it is therefore impossible to determine the mechanical advantage of a pulley, as is done in the case of a wheel and axle.

The efficiency of a pulley depends on the amount of rope wound on it, which is determined by the friction of the sheaves, as well as by the stiffness of the rope. The efficiency of a pulley is given by

\[ \text{Efficiency} = \frac{E}{W} \]

In the case of a double pulley, the efficiency is

\[ \text{Efficiency} = \frac{E}{2W} \]

The efficiency of a pulley is always less than unity, and the mechanical advantage is always greater than unity when the load is self-sustained, and we thus obtain a relation between R and E in the form \( t - a/2 - c \), which shows to a first approximation, that as \( c \) approaches unity a high efficiency is obtainable, while the self-sustaining power of the tackle is retained. The Weston differential pulley block is a typical example. The upper pulley carries a pair of chain pulleys A (fig. 6), secured together by a pinion toothed wheel, and the lower pulley is secured to a pinion toothed wheel, with an endless chain D and d. The pulley block is passed through guides C and D, encircles these pulleys and the single loose pulley E of the lower block, as indicated. With this arrangement a single revolution of the upper sheave causes a double revolution of the pulley block on one side by an amount \( \pi D \), and to unwind an amount \( \pi d \) on the other side, and in consequence the lower sheave is raised by \( \pi (D - d)/2 \). Hence, neglecting friction, E = \( \frac{1}{2} \pi (R + M) \), i.e. E = \( \frac{1}{2} \pi (R - d/D) \). The advantage of the pulley block is increased, if a greater difference of E from R is required, a further mechanical advantage can be obtained by employing a separate hand-wheel and chain, or by forming the upper sheave with an annular spur-pinion wheel. The pulley block is then an endless chain, as in the Tangye form of Weston pulley-block. The efficiency of the Weston pulley-block is less than 50%, and it does not therefore overhaul. An objection to this form of block is the great length of the chain, which may sag on the ground and pick up dirt and grit, and thereby interfere with the smooth working of the mechanism. Other forms, which do not require so lengthy a chain, sometimes employ an epicyclic train to obtain the reduced advantage. The Moore and Head block has two equal chain-wheels A, B, fig. 7, loosely mounted on an axle C, and provided with annular toothed gear-wheels which usually differ by one tooth. A spur pinion D, gearing with both wheels, is carried loosely on an eccentric E forming part of the central pin, so that this latter is turned by the hand-wheel F and chair G the axis of the pinion describes a circle the diameter of which equals the throw of the eccentric, and a small relative motion of the two sheaves takes place, depending on the number of the teeth of the spur wheels. The motion obtained is divided between the two vertical parts of the chain H, which is wound round each sheave in opposite directions, with a free loop I between, while the ends are attached to the lifting hook. This form is self-sustaining at all loads.

In order to obtain a self-sustaining pulley tackle, which will have an efficiency of more than 50%, various arrangements are adopted, which, during lifting automatically throw out a great advantage and cause it to come into action again after the weight is removed. A worm-gear tackle of this description is shown in fig. 8, in which a worm 7, which latter turns loosely in the casing and is provided with a pawl not shown in the figure; this pawl allows freedom of motion when the load is being raised, the frictional grip between the two surfaces prevents return motion of the worm shaft and the load remains suspended, but it may be lowered by turning the hand-wheel so as to overcome the friction brake. Various other arrangements of friction brakes have been devised to give a resistance proportional to the load.

Blocks, for lifting very heavy weights, are sometimes provided with an electric motor for driving the worm, when the worm is mounted on a pinion wheel, and sometimes carries a spur-pinion gear-wheel with a spur-wheel on the lifting shaft, whereby a much greater mechanical advantage is obtained with a small loss by friction of the spur gearing. The Weston differential pulley block is an example of the latter type, and serves to illustrate this point.

PULLMAN—PUMA

PULLMAN, formerly a town of Cook county, Illinois, U.S.A., and now a part of the city of Chicago. Here are the works of the Pullman Palace Car Company, steel forging plants, and other factories. The place was founded in 1880 by George Mortimer Pullman (1831–1897), the inventor of the Pullman sleeping car, and the founder (1867) of the Pullman Palace Car Company, who attempted to make it a “model town.” Even the public works were the property of the Pullman Company and were managed as a business investment. Popular discontent with the conditions led to the annexation of Pullman to Chicago in 1889, but until 1910 the corporation held most of the property. In June and July 1894 a bitter railway strike developed from a controversy between employed and employers in the Pullman works. (See Chicago and Illinois: History.)

PULPIT (from Lat. pulpitum, a staging, platform: equivalents are Fr. chaire d’église, Ital. pulpito, Ger. Kanzel), a raised platform with enclosed front, whence sermons, homilies, &c., were delivered. Pulpits were probably derived in their modern form from the ambones in the early Christian Church (see AMBO). There are many old pulpits of stone, though the majority are of wood. Those in churches are generally hexagonal or octagonal; and some stand on stone bases, and others on slender wooden stems, like columns. The designs vary accordingly to the periods in which they were erected, having panelled, tracing, cusplings, crockets, and other ornaments then in use. Some are extremely rich, and ornamented with colour and gilding. A few also have fine canopies or sounding-boards. Their usual place is in the nave, mostly on the north side, against the second pier from the chancel arch. Pulpits for addressing the people in the open air were common in the medieval period, and stood near a road or cross. Thus there was one at Spital Fields, and one at St Paul’s, London. External pulpits still remain at Magdalen College, Oxford, and at Shrewsbury. Pulpits, or rather places for reading during the meals of the monks, are found in the refectories at Chester, Beaullieu, Shrewsbury, &c., in England; and at St Martin’s Grammar School, St Germain des Prés, &c., in Paris; also in the cloisters at St Dié and St Lo. Shortly after the Reformation the canons ordered pulpits to be erected in all churches where there were none before. It is supposed that to this circumstance owe many of the time of Elizabeth and James. Many of them are very beautifully and elaborately carved, and are evidently of Flemish workmanship. The pulpits in the Mahomedan mosques, which are known as “mimbars” are quite different in form, being usually canopied and approached by a straight flight of steps. These have a doorway at the foot, with an enriched lintel and boldly moulded head; the whole of the work to this and to the stairs, parapet and pulpit itself being of wood, richly inlaid, and often in part gorgeously painted and gilt.

PULQUE, or PULQUE FUESTE, the national beverage of the Mexican natives. It is prepared by fermenting the juice of a number of species of the agave (agava potatorum, americana, &c.). The cultivation of the agave for purposes of pulque manufacture constitutes a considerable local industry, the capital invested running into several millions sterling. The juice obtained by tapping the agave is termed aguamiel. A quantity of this is allowed to ferment naturally for about ten days, and the product so obtained is termed madre pulque (mother of pulque). A small quantity of this is added to fresh aguamiel, and thereby a rapid fermentation is induced, the pulque being ready for consumption within a day or two. It has a somewhat heavy flavour, resembling sour milk, but it is much esteemed by the natives on account of its cooling, and according to them wholesome and nutritious, properties.

PULSE. (1) (O. Fr. pois, Lat. puli, pulitis, Gr. πός, a porridge of beans, peas, &c., in botany, a collective term for beans, peas, and other members of the order Leguminosae (q.v.), which is characterized by having a legume or pod for the fruit. (2) (M. Eng. pou, pouce, O. Fr. pous, mod. pouce, Lat. pulsus, sc. venarum, the beating of the veins, pollere, to drive, beat), throbbing or beating; in physiology the rhythmical beating due to the changes of blood-tension in the arteries consequent on the contractions of their elastic tissues (see Vascular System).

PULSKY, FERENCZ AUREL (1814–1897), Hungarian politician and author, was born on the 17th of September 1814 at Eperjes. After studying law and philosophy at the high schools of his native town and Miskolcz, he travelled abroad. England particularly attracted him, and his fascinating book, Aus dem Tagebuch eines in Grossbritannien reisenden Ungarn (Pesth, 1837), gained for him the membership of the Hungarian Academy. Elected to the Reichstag of 1840, he was in 1848 appointed to a financial post in the Hungarian government, and was transferred in like capacity to Vienna under Esterhazy. Suspected of intriguing with the revolutionists, Pulsky fled to Budapest to avoid arrest. Here he became an active member of the committee of national defence, and when obliged to fly the country he joined Kossuth in England and with him made a tour in the United States of America. In collaboration with his wife he wrote a narrative of this voyage, entitled White, Red, Black (3 vols., London, 1853). He was condemned to death (1853) in contumacia by a council of war. In 1856 he went to Italy, took part in Garibaldi’s expedition to Aspromonte (1862), and was interned as a prisoner of war in Naples. Amnestied by the emperor of Austria in 1866, he returned home and re-entered public life; was from 1867–1876, and again in 1884, a member of the Hungarian Diet, joining the Déak party. In addition to his political activity, he was president of the literary section of the Hungarian Academy, and director of the National Museum at Budapest, where he became distinguished for his archaeological researches. He employed his great influence to promote both art and science and Liberal views in his native country. He died on the 9th of September 1897. Among his writings are Die Jacobiner in Ungarn (Leipzig, 1851) and Eleiet és Korom (Pest, 1880), and many treatises on Hungarian questions in the publications of the Academy of Pest.

Some Reminiscences of Kossuth and Pulsky were published by F. W. Newman in 1888.

PULTUSK, a town of Russian Poland, in the government of Warsaw, 33 m. N. of the city of Warsaw, on the right bank of the Narew. Pop. (1897), 15,878. The town was almost entirely destroyed by fire in 1875. It is now well built, and had before the fire a palace (1319) which was formerly a residence of the bishops of Plock. The industries include woollen, linen and hosiery mills, copper works and potteries. In 1703 Charles XII. of Sweden defeated and captured the greater part of a Saxon army near this town, and in the same locality the French defeated the Russians in December 1806. The town was founded as early as 956.

PUMA, a name, probably of native origin, introduced into European literature by the early Spanish writers on South America (as Garcilaso de la Vega and Hernandez) for one of the largest cats (Felis coulour) of the New World. It is generally called couguar” by the French, “leon” by the Spanish Americans, and “panther” by the Anglo-American hunters of the United States (see CARNIVORA). Though often spoken of as the American lion, chiefly on account of its colour, it rather resembles the leopard of the Old World in size and habits: usually measuring from nose to root of tail about 40 in., the tail being rather more than half that length. The head is small compared with that of other cats and has no mane. The ears are large and rounded. The tail is cylindrical, with some bushy elongation of the hairs near the end, but not forming a distinct tuft. The general colour of the upper parts and sides of the adult is a tawny yellowish brown, sometimes having a grey or silvery shade, but in some cases dark or inclining to red; and upon these and other differences which are probably
PUMICE—PUMP

constant locally, a number of sub-species have been named. The lower parts, inner surface of the limbs, throat, chin and upper lip are dirty white; the outside of the ears, particularly at their base, and a patch on each side of the muzzle black; the end of the tail dusky. The young are, when first born, spotted with dusky brown and the tail ringed. These markings generally fade, and quite disappear before the animal becomes full grown.

The puma has an exceedingly wide range of geographical distribution, extending over a hundred degrees of latitude, from Canada in the north to Patagonia in the south, and formerly was generally diffused in suitable localities from the Atlantic to the Pacific Ocean, but the advances of civilization have curtailed the extent of the districts which it inhabits. In Central America it is still common in the dense forests which clothe the mountain ranges as high as 8000 or 9000 ft. above the sea level. Though an expert climber, it is by no means confined to wooded districts, being frequently found in scrub and reeds along the banks of rivers, and even in the open pampas and prairies. Its habits much resemble those of the rest of the group to which it belongs; and, like the leopard, when it happens to come within reach of an abundant and easy prey, as the sheep or calves of an outlying farming station, it kills far more than it can eat, either for the sake of the blood only or to gratify its propensity for destruction. It rarely attacks man, and when pursued escapes if possible by ascending trees. Several instances have occurred of pumas becoming tame in captivity. Edmund Kean, the actor, had one which followed him about like a dog. When caressed pumas purr like domestic cats.

PUMICE (Lat. pumex, spumex, spuma, froth), a very porous, froth-like, volcanic glass. It is an igneous rock which was almost completely liquid at the moment of effusion and was so rapidly cooled that there was no time for it to crystallize. When it solidified the vapours dissolved in it were suddenly released and the whole mass swelled up into a froth which immediately consolidated. Had it cooled under more pressure it would have formed a solid glass or obsidian (q.v.); in fact if we take fragments of obsidian and heat them in a crucible till they fuse they will suddenly change to pumice when their dissolved gases are set free. Hence it can be understood that pumice is found only in recent volcanic countries. Artificial substances resembling pumice can be produced by blowing steam through molten glass or slag, and when a mass of slag is suddenly cooled by being tipped into the sea (as is the case at the blast furnaces of Whitehaven in Cumberland) it swells up into a pumiceous form so light and full of vesicles that it will float on water. Any type of lava, if the conditions are favourable, may assume the pumiceous state; but basalt and andesites do not so often occur in this form as do trachytes and rhyolites. Pumices are most abundant and most typically developed from andesite which reason they usually accompany obsidians, in fact in Lipari and elsewhere the base of a lava flow may be black obsidian while the upper portion is a snow white pumice.

Small crystals of various minerals occur in many pumices; the commonest are felspar, augite, hornblende and zircon. If they are abundant they greatly diminish the economic value of the rock, as they are hard and wear down more slowly than the glassy material; consequently they produce scratches. The cavitites of the pumice are sometimes rounded, but may also be elongated or tubular owing to the flowing movement of the solidifying lava. The glass itself forms threads, fibres and thin partitions between the vesicles. Rhyolite and trachyte pumices are white, contain 60 to 75% of silica and the specific gravity of the glass is 2.3 to 2.4; andesite pumices are often yellow or brown; while pumiceous basalts, such as occur in the Sandwich Islands, are pitch black when freshly formed.

Good pumice is found in Iceland, Hungary, Nevada, Teneriffe, New Zealand, Pantellaria and the Lipari Islands. The last-named are the chief sources of pumice for the arts and manufactures. At Campo Bianco in Lipari there is an extinct volcanic cone with a breached crater from which a dark stream of obsidian has flowed. For industrial purposes the best varieties are obtained from Monte Pellegrino and Monte Briona. The pumice is extracted by means of shafts and tunnels driven through the soft incoherent stone. It is brought out in blocks of irregular shape and size and is trimmed into slabs and graded into several qualities before it is exported to Canneto, which is the centre of the pumice trade. The workmen say that even pumice occurs in beds or veins, which are probably lava flows and are separated by valueless rock or by obsidian. Its value depends entirely on the regularity, size and shape of the steam cavities and on the absence of minute crystals. From time immemorial there has been a tradition of pumice being one of the principal sources of wealth to the inhabitants of this island. An inferior pumice, known in Lipari as Alessandrina, is used for smoothing oilcloth. Though all the Aeolian Islands are volcanic no pumice is exported from any of the others. In Iceland and Hungary pumice also occurs, but not in sufficient quantity or of such quality as to render it worth working on a large scale. It is estimated that in Lipari there are 170 pumice quarries (or mines) giving employment to 1200 persons and producing 6000 tons of pumice per annum. The price varies with the quality: from 3 lire per 100 kilograms for the commonest sorts to 200 or 300 lire for the best pieces, the average being about 15 lire. Much pumice is used by shipbuilders for the construction of ships, and is crushed, mixed with water to produce a cement, and then shaped by blowing air and forms an ingredient of metal polishes and some kinds of soap. It is often confounded with diatom earth or triopoli powder, but can easily be recognized by the aid of the microscope by simple chemical tests.

Aging the older the pumice occurs, but usually has its cavities filled up by deposits of secondary minerals introduced by percolating water; hence it is of no value for industrial purposes. Pumice, in minute fragments, has been shown to have an extremely fine distribution over the earth's surface at the present day. It occurs in all the deposits which cover the floor of the deepest portion of the oceans, and is especially abundant in the abysmal red clay. In some measure this pumice has been derived from submarine volcanic eruptions, but its presence is also accounted for by the fact that pumice will float on water for months, and is thus distributed over the sea by winds and currents. After a long time it becomes waterlogged and sinks to the bottom, where it gradually becomes incorporated in the sedimentary deposits which are gathering there. After the great eruption of Krakatoa in 1883 banks of pumice covered the surface of the sea for many miles and rose in some cases for four or five ft. above the water level. In addition to this it is blown to a great height and was borne away by the winds, ultimately settling down in the most distant parts of the continents and oceans.

PUMP, a machine which drives a liquid from one point to another, generally at different levels, the latter being usually the higher; an air-pump is an appliance for exhausting or introducing air into vessels, and for dividing or uniting vessels containing liquids.

The word appears apparently first in English in the Prometheus Parvulorum, c. 1440, of a ship's pump (haustorium), in Dutch (pompe), a little later, dialectically, of a conduit pipe for water, but in the sense of a large air-pump it occurs in Germany before the 17th century. The Fr. pompe is derived from Teut. The Ger. variant of Pumpe is Plumppe, which is generally taken as being an echoic word, imitating the sound of the plunger, but the primary notion seems to be that of a pipe or tube. To plump, in the sense of "to make more vivid, to sharpen, to pip" (see the note on the word in the New English Dictionary).
removing the air or other gas from a vessel, whilst a compression pump compresses the air. The simplest forms of pumps employed for forming liquid in vessels are of the form of an engine, in which the portion of essentially of a piston moving in a cylinder, provided with inlet and outlet pipes, together with certain valves. The disposition of these valves divides this type of pump into suction and force pumps.

Fig. 1 shows the arrangement in a suction pump. A is the cylinder within which the piston B is moved up and down by the rod C. D is the inlet pipe (the lower extremity of which is placed beneath the liquid to be removed), and G is the outlet pipe. E is a valve in the inlet pipe opening into the cylinder; and the piston is perforated by one or more holes, each fitted with valves opening outwards on its upper surface. On raising the piston the valve F remains closed and a vacuum tends to be created in the cylinder, but the pressure of the atmosphere forces the liquid up the tube D and it raises the valve E and passes into the cylinder. On reversing the motion the valve E closes and the liquid is forced through the valve F to the upper part of the cylinder. On again raising the piston, the lower part of the cylinder, whilst the previously raised liquid is ejected from the delivery pipe. Obviously the action is intermittent. Moreover, the height of the liquid is conditioned by the driving force, and since this equals 34 ft. of water, the lift cannot be theoretically more than this distance when water is being pumped. In practice it may be considerably less, owing to leakage at the valves and between the piston and cylinder.

In the force pump (fig. 2) there is no such limitation to the lift. In this case the piston is solid, and the outlet pipe, G which is placed at the bottom of the cylinder, has a valve F opening outwards, the inlet pipe and valve are the same as before. On raising the piston the liquid rises in the cylinder, the valve E opening and F remaining shut. On reversing the piston, the lower part of the cylinder, whilst the previously raised liquid is ejected from the delivery pipe. It is seen that the action is intermittent, liquid only being discharged during a down stroke. Moreover, this mechanical force is that which is supplied to the piston rod, the lift is only conditioned by the power available and a continuous supply can be maintained. The air-pump, therefore, being driven by a means of the lift, forms the basis of the air-pump.

**Air-pumps.**—Pumps for evacuating vessels may be divided into three classes: (1) mechanical, (2) mercurial, and (3) jet pumps; the last named are treated in Hydraulic.

**Mechanical.**—The invention of the mechanical air-pump is generally attributed to Oeg von Guericke, consul of Magdeburg, who exhibited his instrument by 1654; it was first described by Gaspar Schott, professor of mathematics at Württemberg, in his *Mechanica hydraulico-pneumatica*, and afterwards (in 1672) by Guericke in his *Experimenta nova Magdeburgica de vacuo stopia.* It consisted of a spherical glass vessel opening below by means of a stop-cock and narrow nozzle into the cylinder of an “exhausting syringe,” which inclined upwards from the extremity of the nozzle. The cylinder, in which a well-fitting piston worked, was provided at its lower end with two valves. One of these opened from the nozzle into the cylinder, the other from the cylinder into the outside air. During the down-stroke of the piston the former was pressed home, so that no air entered the nozzle and vessel, while the latter was forced open by the air which so escaped from the cylinder. During the return-stroke the latter was kept closed in virtue of the partial vacuum formed within the cylinder, while at the same time the former was forced open by the pressure of the denser air in the vessel and nozzle. Thus, at every complete stroke of the piston, the air in the vessel or receiver was diminished by that fraction of itself which is expressed by the ratio of the volume of the available cylindrical space above the outward opening valve to the whole volume of receiver, nozzle and cylinder. The action is essentially that of the common suction pump. The construction was subsequently improved by many experimenters, notably by Boyle, Hawksbee, Smee and others; and more recently two pump barrels were employed, so obtaining the same degree of exhaustion much more rapidly. This type of pump is, however, not very efficient, for there is not only leakage about the valves and between the piston and cylinder, but at a certain degree of exhaust the air within the vessel is insufficient to raise the inlet valve; this last defect has been met in some measure by using an extension of the piston to open and close the valve.

The so-called oil-air-pumps are much more efficient; the valve difficulty is avoided, and the risk of leakage minimized; whilst in addition there is no air clearance between the piston and the base of the cylinder as in the older mechanical forms. The Fleuss pump may be taken as an example. The piston, provided with a valve opening upwards, is packed in the cylinder by a leather cup which is securely pressed against the sides of the cylinder by the atmospheric pressure. The piston rod passes through a valve in the upper part of the cylinder which is held to its seat by a spring. The inlet pipe enters an elliptical vessel which communicates with the cylinder a little way up from its base, whilst at the base there is a relief tube leading into the elliptical vessel already mentioned. Oil is placed both above the upper valve seating, and also in the cylinder up to the height of the lower edge of the inlet pipe. The action is as follows: On raising the piston it cuts off communication with the inlet pipe and then-compresses the air above, forcing it through the upper valve and oil into the atmosphere. Some of the oil is also driven out, but as the valve does not close until the piston has descended a short distance, a certain amount of oil returns. On lowering the piston its valve opens and air passes in from the vessel to be exhausted; this is further raised on the next stroke and so on. The Max Kohl pumps are based on the same principle, but are constructed with more elaborate detail, leading to a greater efficiency, an exhaust of 0-0008 mm. being claimed as readily obtainable.

The invention of the barometer and Torricelli’s explanation of the vacuity above the mercury column placed before the members of the Florentine academy a ready method of obtaining vacua; for to exhaust a vessel it was only necessary to join, by means of a tube provided with stop-cocks, the vessel to a barometer tube, fill the compound vessel with mercury and then to invert it in a basin containing this liquid, whereupon the mercury column fell, leaving a Torricellian vacuum in the vessel, which could be removed after shutting off the stop-cocks. This was the only method known until the invention of the mechanical air-pumps; it was subsequently employed by Count Rumford, and as late as 1845, Edward A. King patented filament electric lamps exhausted by the same process.

**Mercurial.**—Although modern mercurial pumps have assumed a multiplicity of forms, their actions can be reduced to two principles, one statical, the other hydrodynamical—at the same time instruments have been devised utilizing both these principles.

**Statical Pumps.**—The earliest mercurial pump, devised by Swedenborg and described in his *Miscellanea observata circa res naturales* (1722), was statical in action, consisting essentially in replacing the solid piston of the mechanical pump by a column of mercury, which by being alternately raised and lowered gradually exhausted a vessel. A more complicated pump, but of much the same principle, was devised in 1784 by Joseph Baader, to be improved by C. F. Hindenburg in 1787, by A. N. Edelcrantz in 1804 and by J. H. Patten in 1824; whilst in 1851 Rankine Kennedy resuscitated the idea for the purpose of exhausting filament electric lamps. The pump devised by
PUMPKIN—PUN

H. Geissler of Bonn, and first described in 1858 by W. H. Theodor Meyer in a pamphlet Uber das geschickte elektische Licht surpassed all previous forms in both simplicity and efficiency.

The general scheme of Geissler's pump is shown in fig. 3. A and B are pear-shaped glass vessels connected by a long narrow India-rubber tube, which must be sufficiently strong in the body (or strengthened by a linen coating) to stand an outward pressure of \( \pi \) to \( \frac{10}{4} \) atmospheres. A terminates below in a narrow vertical tube \( c \) which is a few inches longer than the height of the barometer, and to the lower end of this tube the India-rubber tube is attached which connects A with B. At the upper end of A is a glass two-way stop-cock, by turning which the vessel A can either be made to communicate with the vessel to be exhausted, or with the atmosphere, or can be shut off from both when the cock holds an intermediate position. The apparatus, after having been carefully cleaned and dried, is charged with pure and dry mercury which must next be worked backwards and forwards between A and B to remove all the air-bells. The air is then driven out of A by lifting B to a sufficient level, turning the cock to connect A with the vessel to be exhausted, causing the gas to expand into and almost fill A. The cock is now shut against both communications, the reservoir lifted, the gas contents of A discharged and so on, until, when after an exhaustion mercury is let into A, the metal strikes against the top without interposition of a gas-bell. In a well-made apparatus the pressure in the exhausted vessel is now reduced to \( \frac{1}{3} \) or \( \frac{1}{5} \) of a millimetre, or even less. An absolute vacuum cannot be produced on account of the unavoidable air-film between the mercury and the walls of the apparatus.

As it takes a height of about 30 inch of mercury to balance the pressure of the atmosphere, a Geissler pump necessarily is a somewhat long-legged and unwieldy instrument; in addition, the long tube is liable to breakage, and can be shortened only by the two vessels A and B brought more closely together, and the somewhat objectionable India-rubber tube be dispensed with, if we connect the air-space in B with an ordinary air-pump, and by means of it do the greater part of the sucking and the whole of the lifting work. An instrument thus modified was constructed by Poggendorff in 1865.

Even a Geissler's stop-cock requires to be lubricated to be absolutely gas-tight, and this occasionally proves a nuisance. Hence a number of attempts have been made to do without stop-cocks altogether. In the pump generally attributed to Töpler, but which was previously devised by J. M. of Warsaw in 1828, who termed it a "innovation pump with low consumption," this is attained by using, both for the inlet and the outlet, vertical capillary glass tubes, soldered the former to somewhere near the bottom, the latter to the top of the vessel. These tubes, being more than 30 inch in height, obviously act as efficient means of exhausting the already considerable height of the pump is thus multiplied by two. This consideration led Alexander Mitscherlich, N. Neisen and others to introduce glass valves in lieu of stop-cocks. A pump similar to Töpler's construction was devised by Mendelejoff, and the original device has been much improved by Wiedemaur, Bessel-Hagen and others.

The best-known pump of this type was invented in 1865 by H. Sprengel, although the idea had been previously conceived by Magnus and Buff. The instrument, in its original (simplest) form (fig. 4), consists of a vertical capillary glass tube \( a \) of about 1 mm. bore, provided with a lateral branch \( b \) near its upper end, which latter, by an India-rubber joint governable by a screw-clamp, communicates with a funnel. The lower end is bent into the shape of a

hook, and dips into a pneumatic trough. The vessel to be exhausted is attached to \( b \) and, in order to extract its gas contents, a properly regulated stream of mercury is allowed to fall through the vertical tube. Every drop of mercury, as it enters from the funnel, entirely closes the narrow tube like a piston, and in going past the place where the side tube enters entraps a portion of air and carries it down to the trough, where it can be collected. If the vertical tube, measuring from the point where the branch comes in, is a few inches greater than the height of the barometer, and the glass and mercury are perfectly clean, the apparatus slowly but surely produces an almost absolute vacuum.

The great advantages of Sprengel's pump lie in the simplicity of its construction and in the readiness with which it adapts itself to the gases. It did excellent service in the hands of Graham for the extraction of gases occluded in metals. Many improvements on the original construction have been proposed.

Many other devices have been introduced for facilitating the production of vacua. For example Raps in 1893 described an automatic arrangement to be used in connexion with a Töpler pump; whilst in 1893 Schulze-Berge devised a rotary form. For the description of these forms see Winkelmann, Handbuch der Physik (1906), 1, 1316. The history of mercurial pumps is treated by S. F. Thompson, The Development of the Mercurial Air Pump (1888).

For the production of high vacua, see VACUUM TUBE; LIQUID GASES.

PUMPKIN, the fruit of the gourd Cucurbita Pepo, well-known in English cottage gardens, and largely cultivated in continental Europe and North America. The pumpkin varies much in form, being sometimes nearly globular, but more generally oblong or ovoid in shape; the rind is smooth and very variable in colour. It is a useful plant to the American backwoods farmer, yielding, both in the ripe and unripe condition, a valuable fodder for his cattle and pigs, being frequently planted at intervals among the maize that constitutes his chief crop. The larger kinds acquire a weight of 40 to 80 lb but smaller varieties are in more esteem for garden culture. When ripe the pumpkin is boiled or baked, or made into various kinds of pie, alone or mixed with other fruit; while small and green it may be eaten like the vegetable marrow. The name squash is applied in America to this and other species of the genus Cucurbita. The name is adapted from an American Indian word (see L. H. Bailey, Cyclopaedia of American Horticulture, where is a fuller account of the squashes).

Summer squashes are mostly varieties of C. Pepo; winter squashes are either C. maxima or C. moschata, chiefly the former. The varieties of pumpkins and squashes are numerous and of great variety in size and shape; it is difficult to keep them pure if various kinds are grown together, but the true squashes (C. maxima) do not hybridize with the true pumpkin species. If carefully handled to avoid cracking of the skin, and kept dry and fairly warm, winter squashes may be kept for months.

PUN, a play upon words, particularly the use of a word in two or more different applications or of two or more words similar in sound but with different meanings by which a humorous or ludicrous effect is produced; thus Charles 1.'s Court Jester is said to have made the punning grace "great praise be to God and little Laud to the devil" for which the archbishop dismissed him from his service. Another famous pun was that upon The Beggar's Opera, which "made Gay rich and Rich gay." Thomas Hood was the king of pun-makers. "They went and told the sexton, and the sexton told the bell" ("Sally Brown") is one example among the innumerable puns with which his poems are filled. The derivation of the word is not known. It first appears in the second half of the 17th century. Skeat
PUNCH, the abbreviated form of Punchinello (Ital. Pulcinella, Pulcinella), the most popular of the puppets or marionettes (q.v.), and the chief figure in the "Punch and Judy" show. It is of Italian origin, though its history is by no means free from obscurity. The earlier etymologists sought to trace the name to various mythical Italian goddesses (Aurelia, Brigitta, etc.), but the character was first furnished, F. Galliani adopts the theory which derives it from the name of Puccio d'Aniello, a vintager near Naples, who, having by his wit and grotesque appearance vanished some storytelling comedians in their own sphere, was induced to join the troop, and whose place, by reason of his popularity, was supplied after his death by a masked actor who imitated his dress and manner. The claims of other individuals—Paolo Cinella, Pollicino, and Pulcinella, a Neapolitan dealer in fools—have also found supporters, and the derivation of the name and character from some old mystery representing Pontius (O. Eng. Pouns; Fr. Ponce) Pilate and Judas, or the Jews, was formerly popular. It has even been suggested that the title is a modification of pollo sarca (I move much) as expressive of the restlessness which is characteristic of the puppet; and the assumption that the character was invariably of diminutive size has given rise to its reference to the word puntiglio, (the diminutive of puntone, a small, fine point, a caviar or quibble. No historical connexion, however, has been found between the words.

Punch, having beat obscurity. It appearance or individuals expressive as "chicken" was and and sentative sceniche hood transmitted Pulcinella. to is slang the diminutive Baretti, the between assumption in Italian Neapolitan imitation was popularity, imitated was in the character the peasants of Accera. This would place the origin of the Italian Pulcinella somewhere about the commencement of the 17th century, the original character appearing to have been of that a country clown, hook-nosed, shrill-voiced, cowardly, boastful and often stupid, yet given at times to knavish tricks and shrewd sayings. In thorough accordance with this date, we find that the earliest known appearance of Polichinelle in France is at the beginning of the reign of Louis XIV., in the show of the puppet-playing dentist Jean Brioché. It might have been expected that the shrewd and wittier side of the character would most commend itself to the French mind, and there is good reason to believe that the Polichinelle of Brioché was neither a blunderer nor a fool. The puppet was almost immediately seized upon as the medium of political satire of the kind exemplified in the Letter of Polichinelle to Cardinal Masarin (1649), and it is described in the Combat du Cyrayo de Bergerac, as a "petit Esope de bois, remuant, tournant, virant, dansant, riant, parlant, petant" and as "cet hétéroclite marmouset, disons mieux, ce drolifique boosu." In this there appears signs of transformation, whether the importation to France took place before or after the alleged Improvements of Caïcées. The punchback had been long associated in France with wit and laughter, and there are, therefore, ad abounding among Pepys's and Defoe's diaries to make it probable that the northern Punch was of French origin, a Gallic type under an Italian name, though there does not seem to be sufficient reason for adopting his suggestion that Polichinelle was a burlesque portrait of Béarnais. The date of its introduction into England has been disputed, J. Payne Collier being of opinion that Punch and King William came together, a second theory suggesting an earlier origin with the Huguenot refugees. In view of its popularity in France prior to the Restoration, however, it would be strange if its migration had been so long delayed, and it is more than probable that it crossed the channel in the wake of the Royalists. Apart from the general references by S. Pepys (1662) and by J. Evelyn (1667) to an Italian puppet-show at Covent Garden, the former makes mention (1669) of some poor people who called their fat child Punch, "that word being become a word of common use for all that is thick and short." An allusion to "Punchinells" in Butler's Satire on English Imitation of the French, and Aubrey speaks of "a Punchinello holding a dial" as one of the ornaments of Sir Samuel Lely's house at Whitehall. But, though the puppet did not travel in the train of William of Orange, allusions to it became far more frequent after the Revolution of 1688, and the skill of the Dutch in their treatment of puppet mechanism may have enhanced its attractiveness. In 1703 it was introduced at Bartholomew Fair into a puppet play of the creation of the world; in 1709 (Taller, No. 16) it was to be found in a representation of the Deluge, though in a different part from that of the Monus Polichinelle of Alexis Piron's Arlequin-Dessaloon (1722); and in 1710 (Spectator, No. 14) it is mentioned as a leading figure in Powell's puppet-show at Covent Garden. The alleged satire on Robert Walpole, entitled A Second Tale of a Tub, or the History of Robert Powell, the Puppet-Showman (1715), furnishes some details of Punch's performance, and has an interesting wood-piece representing Powell with Punch and his wife. The Judy (or Joan, as she appears to have been sometimes called) is not of a specially grotesque order, but the Punch is easily recognizable in all but the features, which are of the normal puppet type.
Other allusions are to be found in Gay's *Shepherd's Week—
Saturday* (1731) and Swift's *Dialogue between Mad Mundinus and
Timothy* (1728). The older Punchinello was far less restricted
in his actions and circumstances than his modern successor. He
fought with allegorical figures representing want and wear-
iness as well as with his wife and with the police, was on intimate
terms with the patriarochs and the seven champions of Christen-
dom, sat on the lap of the queen of Sheba, had kings and dukes
for his companions, and cheated the Inquisition as well as the
common hangman. Powell seems to have introduced a trained
pig which danced a minuet with Punch, and the French (among
whom Punch is now usually styled Guignol, originally a puppet
hailing from Lyons) having occasionally employed a cat in the
place of the dog Toby, whose origin is somewhat uncertain.
A typical version of the modern play, with illustrations, was
published by Payne Collier and Cruikshank in 1828 (3rd ed.,
1844).

(R. M. W.)

**PUNCH.** (1) To pierce, perforate, make a hole or stamp a
mark, &c., with a tool known as a "punchon" or "punch." The
verb is derived from the substantive; the original is Lat.
*punctio,* a pricking, from *pungere,* to prick. This gave Ital.
*punzone,* O. Fr. *poinson,* mod. *poison.* Both these French
forms mean also a cask, from which the English "puncheon,"
(a liquid measure varying in capacity from 72 to 120 gallons is
taken. This is probably the same word as that for the tool,
and refers to a mark or sign stamped or "punched" on the cask.
The origin may therefore be paralleled by the explanation of
"hogshead" as referring to a mark of an "oxhead" branded
on the measure. (2) To beat or hit, especially in such collo-
quialisms, as "to punch one's head." This is not the same word
as (1) but is a shortened form of "punish," from Lat. *punire,*
of which the ultimate origin is *poena,* penalty, from which is
derived "pain." (3) The name of a drink, composed of spirits,
water, sliced lemons or limes, or lemon-juice, together with
sugar and spice, and served hot. According to the spirit with
which it is made, it is known as brandy, whisky, rum-punch, &c.
Milk-punch is made of milk and spirit, bottled and served cold.
The word is the English representative of the Hindostani *panch,*
five (from the number of ingredients), and was introduced from
the East.

**PUNCTUATION** (Lat. *punctum,* a point), the theory or art of
"pointing" a literary composition so as to divide it properly
into sentences and portions of sentences, which the "points"
are used to mark at their close, with a view to precision in the
meaning of a continuous set of written words, by the indication
of what would be pauses or changes of expression if they were
spoken. The uses of the chief "points" are explained as fol-
lows in the "Rules for Compositors" at the Oxford University
Press, compiled by Mr Horace Hart, the university printer:
The "full stop" or "period" () marks the end of a sentence.
The "colon" (;) — Greek *κώδων,* a limb—is at the transition
point of the sentence. The "semicolon" (;) separates different
statements. The "comma" (,) — Gr. *σημα.* This separates,
periods of self-contained clauses, phrases, and particles.
(The terms "period" — Greek *περιόδος* — "colon," "comma,"
now identified in punctuation with the signs here given, were
borrowed from the Greek grammarians, who originally described
either the whole sentence or a longer or shorter part of it
respectively in this way.) Among other signs, the "dash" (
—) marks abruptness or irregularity. The "exclamation"
(!) marks surprise. The "interrogation" or "query" (?) asks
the question. The "apostrophe" (') marks elisions or the possessive
case. "Quotes," quotation-marks or "inverted commas" ("")
define quoted words. Irregularities or interpolations in a
sentence are marked by various forms of bracket (,) or paren-
thesis. Literary usage and the practice of printing-houses vary,
however, so much that it is impossible to define exactly and
shortly the part played by some of these points in a reasonable
system of punctuation. The Oxford Rules already mentioned,
which deal also with spelling and other pitfalls in literary
composition and printing, carry the authority of such experts
as Dr J. A. H. Murray and Dr Henry Bradley; and the art of
punctuation may be studied also in such works as H. Beadnell's
*Spelling and Punctuation,* P. Allardyce's *Stops: or how to
punctuate,* T. L. de Vinne's *Correct Composition,* and T. Lefèvre's
*Guide pratique du compositeur.* The acceptance of a conven-
tional system of modern punctuation is mainly due to the
invention of printing, and to the ingenuity and care of individual
typographers. In the earlier forms of writing the letters ran
on continuously in lines; it was only by degrees that actual
words were divided from one another by spacing within the
line; then later came the distribution of words into sentences
by means of points, and the introduction by Aldus Manutius
in the 16th century of a regular system for these. The chief
signs were inherited by the printers from the dots of the Greek
grammarians, but often with altered meanings; thus the Greek
interrogation mark (?) becomes the modern semicolon. (See
PALaeOGRAPHY and TYPOGRAPHY.)

**PUNDIT** (Hindi *pundit,* Skr. *pandita*), a learned man, a teacher,
particularly one skilled in Sanskrit and Hindu law, religion and
philosophy. Before the institution of the High Courts in
1862, the Supreme Court of India had a law officer styled the
Pundit of the Supreme Court, who advised the English judges
on points of Hindu law. The term is frequently applied,
somewhat derisively, or humorously, to learned persons, to
those who claim by long official or other experience to lay down
the law or dictate principles of conduct.

**PUNIC WARS,** a name specially appropriated to the wars
between Rome and Carthage in the 3rd and 2nd centuries B.C.
The origin of these conflicts is to be sought in the position which
Rome acquired about 275 B.C. as suzerain and protector of all
Italy. Her new obligation to safeguard the peninsula against
foreign interference made it necessary that she should not allow
the neighbouring island of Sicily to fall into the hands of a
strong and expansive power. Carthage, on the other hand, had
long been anxious to conquer Sicily and so to complete the
chain of island posts by which she controlled the western
Mediterranean.

First Punic War (264–241 B.C.).—The proximate cause of the
first outbreak was a crisis in the city of Messana, commanding
the straits between Italy and Sicily. A band of Campanian
mercenaries, which had forcibly established itself within the
town and was beinghard pressed in 264 by Hiero II. of Syracuse,
exploited for help both to Rome and Carthage and thus brought
a force from either power upon the scene. The Carthaginians,
arriving first, occupied Messana and effected a reconciliation
with Hiero. The Roman commander nevertheless persisted
in throwing troops into the city, and by seizing the person of
the Carthaginian admiral during a parley induced him to withdraw
his garrison. The Romans thus won an important strategic
post, but their aggression was met by a declaration of war from
Carthage and Syracuse.

Operations began with a joint attack upon Messana, which
the Romans easily repelled. In 263 they advanced with a
considerable force into Hiero's territory and induced him to
seek peace; an alliance with them. Having thus secured their
foothold on the island they set themselves to wrest it completely
from Carthage. In 262 they besieged and captured the enemy's
base at Agrigentum, and proved that Punic mercenary troops
could not stand before the infantry of the legions. But they
made little impression upon the Carthaginian fortresses in the
west of the island and upon the towns of the interior which
mostly sided against them. Thus in the following campaigns
their army was practically brought to a standstill.

In 260 the war entered upon a new phase. Convinced that
they could gain no serious advantage so long as the Carthaginians
controlled the sea and communicated freely with their island
possessions, the Romans built their first large fleet of standard
battleships. At Mylae, off the north Sicilian coast, their
admiral C. Duilius defeated a Carthaginian squadron of superior
manoeuvring capacity by a novel application of grappling and

4The chronology here given is the traditional one, but recent
researches tend to show that many events have been anadated
by one year.
boarding tactics. This victory left Rome free to land a force on Corsica and expel the Carthaginians (259), but did not suffice to loosen their grip on Sicily.

After two more years of desultory warfare the Romans decided to carry the war into the enemy's home territory. A large armament sailed out in 256, repelled a vigorous attack by the entire Carthaginian fleet off Cape Ecnomus (near Agrigentum) and established a fortified camp on African soil at Clypea. The Carthaginians, whose citizen levy was utterly disorganized, could neither keep the field against the invaders nor prevent their subjects from revolting. A single campaign compelled them to sue for peace, but the terms which the Roman commander Atilius Regulus offered were intolerably harsh. Accordingly they equipped a new army in which, by the advice of a Greek captain of mercenaries named Xanthippus, cavalry and elephants formed the strongest arm. In 255, under Xanthippus' command, they offered battle to Regulus, who had taken up position with an inadequate force near Tunes, outmanoeuvred him and destroyed the bulk of his army. A second Roman armament, which subsequently reached Africa after defeating the full Carthaginian fleet off Cape Hermoumum, did not venture to reopen the campaign, but withdrew all the remaining troops.

The Romans now directed their efforts once more against Sicily. In 254 they carried the important fortress of Pangrum (Palermo) by an attack from the sea; but when Carthage threw reinforcements into the island the war again came to a standstill. In 251 at last the Roman general L. Metellus brought about a pitched battle near Panormus in which the enemy's force was effectively crippled. This victory was followed by an investment of the chief Punic base at Lilybaeum by land and sea. The besiegers met with a gallant resistance, and in 240 were compelled to withdraw by the loss of their fleet in a surprise attack upon the neighbouring harbour of Drepanum (Trapani), in which the admiral Claudius Pulcher was repulsed with a loss of 93 ships. Meanwhile other losses in storms on the high seas so reduced the Roman fleet that the attack upon Sicily had to be suspended. At the same time the Carthaginians, who felt no less severely the financial strain of the prolonged struggle and had a war in Africa on their hands, reduced their armaments and made no attempt to deliver a counter-attack. The only noteworthy feature of the ensuing campaigns is the skilful guerilla war waged by a new Carthaginian commander, Hamilcar Barca, from his strong positions on Mt. Erice (247–244) and Mt Eryx (244–242) in Western Sicily, by which he effectually screened Lilybaeum from the Roman land army.

In 242 Rome resumed operations on sea. By a magnificent effort on the part of private citizens a fleet of 200 warships was equipped and sent out to renew the blockade of Lilybaeum. The Carthaginians hastily collected a relief force, but in a battle fought off the Aegates or Aegeusae islands (west of Drepana) their fleet was caught at a disadvantage and mostly sunk or captured (March 10, 241). This victory, by giving the Romans undisputed command of the sea, rendered certain the ultimate fall of the Punic strongholds in Sicily. The Carthaginians accordingly opened negotiations and consented to a peace by which they abandoned Sicily and the Lipari Islands to Rome and paid an indemnity of 420 talents (about £800,000).

The Interval between the First and Second Wars (241–218 B.C.).—The loss of naval supremacy not only deprived Carthage of her predominance in the western Mediterranean, but exposed her overseas empire to disintegration under renewed attacks by Rome. The temper of the Roman people was soon made manifest during a conflict which broke out between the Carthaginians and their discontented mercenaries. Italian traders were allowed to traffic in munitions of war with the mutineers, and a gross breach of the treaty was perpetrated when a Roman force was sent to occupy Sardinia, whose insurgent garrison had offered to surrender the island (239). To the remonstrances of Carthage the Romans replied with a direct declaration of war, and only withheld their attack upon the formal cession of Sardinia and Corsica and the payment of a further indemnity.

From this episode it became clear that Rome intended to use her victory to the utmost. To avoid complete humiliation Carthage had no resource but to humiliate her adversary. The recent complications of foreign and internal strife had indeed so weakened the Punic power that the prospect of renewing the war under favourable circumstances seemed remote enough. But the scheme of preparing for a fresh conflict found a worthy champion in Hamilcar Barca, who sought to compensate for the loss of Sicily by acquiring a dominion in Spain where Carthage might gain new wealth and form a fresh base of operations against Rome. Invested with an unrestricted foreign command, he spent the rest of his life in founding a Spanish empire (236–228). His work was continued by his son Hannibal, who was placed at the head of the army in 220. These conquests aroused the suspicions of Rome, which in a treaty with Hasdrubal confined the Carthaginians to the south of the Ebro, and also guaranteed the independence of Saguntum, a town on the east coast which pretended to a Greek origin. In 219 Hannibal laid siege to Saguntum and carried the town in spite of a stubborn defence. It has always been a debatable point whether his attack contravened the new treaty. The Romans certainly took this view and sent to Carthage to demand Hannibal's surrender. But his defiant policy was too popular to be disavowed; the Carthaginian council upheld Hannibal's action, and drew upon itself an immediate declaration of war.

Second Punic War (218–201 B.C.)—The 'Hannibalic' War.—It seemed as though the superiority of the Romans at sea must enable them to choose the field of battle. They decided to embark one army for Spain and another for Sicily and Africa. But before their preparations were complete Hannibal began that series of operations by which he dictated the course of the war for the greater part of its duration. Realizing that so long as Rome commanded the resources of an united Italian confederacy no foreign attack could beat her down beyond recovery, he conceived the plan of cutting off her supply of strength at the source by carrying the war into Italy and causing a disruption of the League. His chances of ever reaching Italy seemed small, for the sea was guarded by the Roman fleets and the land route was long and arduous. But the very boldness of his enterprise contributed to its success; after a six months' march through Spain and Gaul and over the Alps, which the Romans were nowhere in time to oppose, Hannibal arrived in the plain of the Po with 20,000 foot and 6000 horse, the pick of his African and Spanish levies (autumn 218: for details see Hannibal).

His further advance was here disputed by some Roman troops which had been recalled from the Spanish expedition. But the superiority of the Carthaginian cavalry and the spread of insurrection among the Gaulish inhabitants forced the defenders to fall back upon the Apennines. At the end of the year the Roman army was reinforced by the division from Sicily and led out to battle on the banks of the Trebia. Hannibal, by superior tactics, repelled the assailants with heavy loss, and thus made his position in north Italy secure.

In 217 the campaign opened in Etruria, into which the invading army, largely reinforced by Gauls, penetrated by an unguarded pass. A rash pursuit by the Roman field force led to its being entrapped on the shore of Lake Trasimene and destroyed with a loss of 40,000 men. This catastrophe left Rome completely uncovered; but Hannibal, having resolved not to attack the capital before he could collect a more overwhelming force, directed his march towards the south of Italy, where he hoped to stir up the peoples who had formerly been Rome's most stubborn enemies. The natives, however, were everywhere slow to join the Carthaginians, and a new Roman army under the dictator Q. Fabius Maximus ("Cunctator"), which, without ever daring to close with Hannibal, persistently dogged his steps on his forays through Apulia and Campania, prevented his acquiring a permanent base of operations.

The eventful campaign of 216 was begun by a new aggressive move on the part of Rome. An exceptionally strong field army, estimated at 85,000 men, was sent forth in order to crush the Carthaginians in open battle. On a level plain near Cannae in
Apulia, which Hannibal had chosen for his battle-ground, the Roman legions delivered their attack. Hannibal deliberately allowed his centre to be driven in by their superior numbers, while Hasdrubal's cavalry wheeled round so as to take the enemy in flank and rear. The Romans, surrounded on all sides and so cramped that their superior numbers aggravated their plight, were practically annihilated, and the loss of citizens was perhaps greater than in any other defeat that befell the Republic. The moral effect of the battle was no less momentous. The south Italian nations at last found courage to secede from Rome, the leaders of the movement being the people of Capua, the second greatest town of Italy. Reinforcements were sent from Carthage, and several neutral powers prepared to throw their weight into the scale on Hannibal's behalf. At first sight it seems strange that the battle of Cannae did not decide the war. But the resources of Rome, though terribly reduced in respect both of men and of money, were not yet exhausted. On north and central Italy the insurrection spread but little, and could be sufficiently guarded against with small detachments. In the south the Greek towns of the coast remained loyal, and the numerous Latin colonies continued to render important service by interrupting free communication between the rebels and detaining part of their forces. In Rome itself the quarrels between the nobles and commons, which had previously unsettled her policy, gave way to a unanimity unparalleled in the annals of the Republic. The guidance of operations was henceforth left to the senate, which by maintaining a firm and persistent policy until the conflict was brought to a successful end earned its greatest title to fame.

The subsequent campaigns of the Italian War assume a new character. Though the Romans contrived at times to raise 200,000 men, they could only spare a moderate force for field operations. Their generals, among whom the veterans Fabius and M. Claudius Marcellus, held the most important commands, rarely ventured to engage Hannibal in the open, and contented themselves with observing him or skirmishing against his detachments. Hannibal, whose recent accessions of strength were largely discounted by the necessity of assigning troops to protect his new allies or secure their wavering loyalty, was still too weak to undertake a vigorous offensive. In the ensuing years the war resolved itself into a multiplicity of minor engagements which need not be followed out in detail. In 216 and 215 the chief seat of war was Campania, where Hannibal vainly attempted to establish himself on the coast and experienced a severe repulse at Nola. In 214 the main Carthaginian force was transferred to Apulia in hopes of capturing Tarentum. Though Croton and Locri on the Calabrian coast had fallen into his hands, Hannibal still lacked a suitable harbour by which he might have secured his overseas communications. For two years he watched in vain for an opportunity of surprising the town, while the Romans narrowed down the sphere of revolt in Campania and defeated other Carthaginian commanders.

In 212 the Carthaginian power seemed to be breaking up after Cannae. The diversions which Roman diplomacy provided for Philip in Greece and the maintenance of a patrol squadron in the Adriatic prevented any effective co-operation on his part with Hannibal. The campaign of 207 decided the war in Italy. Though Hannibal still maintained himself for some years in Calabria, this was chiefly due to the exhaustion of Rome after the prodigious strain of past years and the consequent reduction of her armaments. In 203 Italy was finally cleared of Carthaginian troops. Hannibal, in accordance with orders from home, sailed back to Africa, and another expedition under his brother Mago, which had sailed to Liguria in 205 and endeavoured to rouse the slumbering discontent in Cisalpine Gaul and Etruria, was driven back on the coast and withdrawn about the same time.

b. The Subsidiary Campaigns.—Concurrently with the great struggle in Italy the Second Punic War was fought out on several other fields. It will suffice merely to allude to the First Macedonian, of 205-202, which was chiefly won by M. Licinius Pera, and to the伊利rian expedition of 212, which was wholly unimportant. The Roman power seemed to be breaking up after Cannae. The diversions which Roman diplomacy provided for Philip in Greece and the maintenance of a patrol squadron in the Adriatic prevented any effective co-operation on his part with Hannibal.

In view of the complete stagnation of agriculture in Italy the Romans had to look to Sardinia and Sicily for their food supply. Sardinia was attacked by a Carthaginian armament in 215, but a small Roman force sufficed to repel the invasion. In Sicily a more serious conflict broke out. Some isolated attacks by Punic squadrons were easily frustrated by the strong Roman fleet. But in 215 the conflict broke out. Some isolated attacks by Punic squadrons were easily frustrated by the strong Roman fleet. But in 215 when Hannibal finally laid siege to Messana, the Romans were compelled to raise a fleet and a force of troops, and Hannibal was driven back to his native Spain.

Spain.

The conflict in Spain was second in importance to the Italian War alone. From this country the Carthaginians drew large supplies of troops and money which might serve to reinforce Hannibal; hence it was in the interest of the Romans to challenge their enemy within his Spanish domain.
Though the force which Rome at first spared for this war was small in numbers and rested entirely upon its own resources, the generals Publius and Gnaeus Scipio by skilful strategy and diplomacy not only won over the peoples north of the Ebro and defeated the Carthaginian leader Hasdrubal Barca in his attempts to restore communication with Italy, but carried their arms along the east coast into the heart of the enemy's domain. But eventually their successes were nullified by a rash advance. Deserted by their native contingents and cut off by Carthaginian cavalry, among which the Numidian prince Massinissa rendered conspicuous service, the Roman generals were slain and their troops were destroyed in detail (212 or 211).

Disturbances in Africa prevented the Punic commanders from reaping the full fruit of their success. Before long the fall of Capua enabled Rome to transfer troops from Spain to Italy, and in 209 the best Roman general of the day, the young son and namesake of the recently slain P. Scipio, was placed in command. The now leader signalized his arrival by a bold and successful coup-de-moi at upon the great arsenal of Carthage, Novo. Though he failed to prevent Hasdrubal Barca from marching away to Italy, Scipio profited by his departure to push back the remaining hostile forces the more rapidly. A last effort by the Carthaginians to retrieve their losses with a fresh army was frustrated by a great victory at Ilipa (near Corduba), and by the end of 206 they were completely driven out of the peninsula.

In 205, Scipio, who had returned to Rome to hold the consulship, proposed to follow up his victories by an attack upon the home territory of Carthage. Though the presence of Hannibal in Italy at first deterred the senate from sanctioning this policy, the general popularity of the scheme overbore all resistance. Scipio was granted a force which he organized and supplemented in Sicily, and in 204 sailed across to Africa. He was here met by a combined levy of Carthage and King Syphax of Numidia, and for a time possession of the island of Utica was at stake. But after an engaging battle, by a surprise attack upon the enemy's camp, which resulted in the total loss of the allied force by sword or flame. In the campaign of 203 a new Carthaginian force was destroyed by Scipio on the Great Plains not far from Utica, their ally Syphax was captured, and the renegade Massinissa (q.v.) reinstated in the kingdom from which Syphax had recently expelled him. These disasters induced the Carthaginians to sue for peace, but before the very moderate terms which Scipio offered could be definitely accepted a sudden reversal of opinion caused them to recall Hannibal's army for a final trial of war, and to break off negotiations. In 202 Hannibal assumed command of a composite force of citizen and mercenary levies stiffened with a corps of his veteran Italian troops. After an abortive conference with Scipio he prepared for a decisive battle at Zama (an inland site not yet identified with certainty). Scipio's force was smaller in numbers, but well trained throughout and greatly superior in cavalry. Hannibal, in order to reach an attack, by the Carthaginian elephants, cut through the first two lines of the enemy, but was unable to break the reserve corps of veterans. The battle was ultimately decided by the cavalry of the Romans and their new ally Massinissa, which by a manoeuvre recalling the tactics of Cannae took Hannibal's line in the rear and completely destroyed it. The Carthaginians having thus lost their last army again applied for peace and accepted the terms which Scipio offered. They were compelled to cede Spain and the Mediterranean islands still in their hands, to surrender their warships, to pay an indemnity of 10,000 talents (about £2,400,000) within fifty years and to forfeit their independence in affairs of war and foreign policy.

The Second Punic War, by far the greatest struggle in which either power engaged, had thus ended in the complete triumph of Rome. This triumph is not to be explained in the main history of the Carthaginians' method of attack. The history of the First Punic War, and that of the Second outside of Italy, prove that the Romans were irresistible on neutral or Carthaginian ground. Carthage could only hope to win by invading Italy and using the enemy's home resources against him. The failure of Hannibal's brilliant endeavour to realize these conditions was not due to any strategical mistakes on his part. It was caused by the indomitable strength of will of the Romans, whose character during this period appears at its best, and to the compactness of their Italian confederacy, which no shock of defeat or strain of war could entirely disintegrate. It is this spectacle of individual genius overborne by corporate and persevering effort which lends to the Second Punic War its peculiar interest.

The Third Punic War (149-146 B.C.)—The political power of Carthage henceforth remained quite insignificant, but its commerce and material resources revived in the 2nd century with such rapidity as to excite the jealousy of the growing mercantile population of Rome and the alarm of its more timid statesmen. Under the influence of these feelings the conviction—sedulously fostered by Cato the Elder, the Censor—that "Carthage must be destroyed" overbore the scruples of more cautious statesmen. A casus belli was readily found in a formal breach of the treaty, committed by the Carthaginians in 154, when they resisted Massinissa's aggressions by force of arms. A Roman army was despatched to Africa, and although the Carthaginians consented to make reparation by giving hostages and surrendering their arms, they were goaded into revolt by the further stipulation that they must emigrate to some inland site where they would be debarred from commerce. By a desperate effort they created a new war equipment and prepared their city for a siege (149). The Roman attack for two years completely miscarried, until in 147 the command was given to a young officer who had distinguished himself in the early operations of the war—Scipio Aemilianus, the adoptive grandson of the former conqueror of Carthage. Scipio made the blockade stringent by walling off the islethus on which the town lay and by cutting off its sources of supplies from overseas. He then took up a position on this island where he effected an entrance in the face of a determined and insistent resistance. The struggle did not cease until he had carried house by house the streets that led up to the citadel. Of a population probably exceeding half a million only 50,000 remained at the final surrender. The survivors were sold into slavery; the city was razed to the ground and its site condemned by solemn imprecations to lie desolate for ever. The territory of Carthage, which had recently been much narrowed by Massinissa's encroachments, was converted into a Roman province under the name of "Africa."

BIBLIOGRAPHY.—1. Ancient Authorities. For the First Punic War Polybius, bk. 1, provides a trustworthy and impartial account, but owing to his conciseness leaves many problems of chronology and strategy unstated. For the Second Punic War 3 of Polybius presents a complete and detailed record down to Carthage, bks. 7-15 contain fragmentary notices of which the most continuous deal with the campaigns of Scipio. Livy (bks. 23-30) gives a continuous and detailed narrative, partly based upon Polybius and other good authorities, partly upon untrustworthy Roman annalists of the period. The Third War is described in Appian’s Res Lysicae, chs. 67 sqq., and the fragments of Polybius, bks. 36-39.

PUNISHMENT (from Lat. punire, to punish, from poena, punishment, Gr. poiein), the infliction of some kind of pain or loss upon a person for a misdeed, i.e. the transgression of a law or command. Punishment may take forms varying from capital punishment, flogging and mutilation of the body to imprisonment, fines, and even death sentences which come into operation only if an offence is repeated within a specified time. The progress of civilization has resulted in a vast change alike in the theory and in the method of punishment. In primitive society punishment was left to the individuals wronged or their families, and was vindictive or retributive: in quantity and quality it would bear no special relation to the character or gravity of the offence. Gradually there would arise the idea of proportionate punishment, of which the characteristic type is the lex talionis; “an eye for an eye.” The second stage was punishment by individuals under the control of the state, or community; in the third stage, with the growth of law, the state took over the primitive function and provided itself with the machinery of “justice” for the maintenance of public order. Henceforward crimes are against the state, and the exaction of punishment by the wronged individual is illegal (cf. Lynch Law). Even at this stage the vindictive or retributive character of punishment remains, but gradually, and specially after the humanist movement under thinkers like Beccaria and Jeremy Bentham, new theories begin to emerge. Two chief trains of thought have combined in the condemnation of primitive theory and practice. On the one hand the retributive principle itself has been very largely superseded by the protective and the reformatory; on the other punishments involving bodily pain have become objectionable to the general sense of society. Consequently corporal and even capital punishment occupy a far less prominent position, and tend everywhere to disappear. It began to be recognized also that stereotyped punishments, such as belong to penal codes, fail to take due account of the particular condition of an offence and the character and circumstances of the offender. A fixed fine, for example, operates very unequally on rich and poor. Modern theories date from the 18th century, when the humanitarian movement began to teach the dignity of the individual and to emphasize his rationality and responsibility. The result was the reduction of punishment both in quantity and in severity, the improvement of the prison system, and the first attempts to study the psychology of crime and to distinguish between classes of criminals with a view to their improvement (see Crime; Prison; Children’s Courts; Juvenile Offenders). These latter problems are the province of criminal anthropology and criminal sociology, sciences so called because they view crime as the outcome of anthropological and social conditions. The man who breaks the law is himself a product of social evolution and cannot be regarded as solely responsible for his disposition to transgress. Habitual crime is thus to be treated as a disease. Punishment can, therefore, be justified only in so far as it (i) protects society by removing temporarily or

permanently one who has injured it, or as acting as a deterrent, or (2) aims at the moral regeneration of the criminal. Thus the retributive theory of punishment with its criterion of justice as an end in itself gives place to a theory which regards punishment solely as a means to an end, utilitarian or moral, according as the common advantage or the good of the criminal is sought.

PUNJAB, a province of British India, so named from the “five rivers” by which it is watered: the Jhelum, Chenab, Ravi, Beas and Sutlej, all tributaries of the Indus. Geographically the Punjab is the triangular tract of country of which the Indus and the Sutlej to their confluence form the two sides, the base being the lower Himalaya hills between those two rivers; but the British province now includes a large tract outside those boundaries. Along the northern border Himalayan ranges divide it from Kashmir and Tibet. On the west it is separated from the North-West Frontier province by the Indus, until that river reaches the border of Dera Ghazi Khan district, which is divided from Baluchistan by the Suliman range. To the south lie Sind and Rajputana, while on the east the rivers Jumna and Tons separate it from the United Provinces.

The Punjab includes two classes of territory, that belonging to the British Crown, and that in possession of 134 feudatory chiefs, almost all of whom pay tribute. The total area of the province is 13,741 sq. m., of which 97,200 sq. m. are British territory and the remainder belongs to native states. The British territory is divided into 20 districts, grouped under the five divisions of Delhi, Lahore, Jullundur, Rawalpindi and Multan; while the native states vary in size from Bahawalpur, with an area of 15,000 sq. m., to the tiny state of Dorkot, with an area of 8 sq. m. and a total population of 518 souls. They may be grouped under three main heads: the Punjlian states of Patiala, Jind and Nabha and the Sikh state of Kipurthana, occupying the centre of the eastern plains; the Mahomedan state of Bahawalpur between the Sutlej and the Rajputana desert; and the hill states, among the Punjab Himalayas held by ancient Rajput families, including Chamba, Mandi, Sakt, Sirutm and the Simla states.

Physical Features.—The mountain regions of the Punjab fall under four separate groups. To the north-east of the province lies the Himalayan system, with the fringing range of the Siwalks at its foot. In the south-eastern corner the Aravalley system sends out insignificant outliers, which run across Gurgaon and Delhi districts and strike the Jumna at Delhi. The lower portion of the western frontier is constituted by the great Suliman chain; while the north-western districts of the province are traversed by the hill system known as the Salt range. The mountain system of the Himalayas, so far as it concerns the Punjab, consists primarily of three great ranges running in a generally north-westward direction from the head-waters of the Sutlej to the Indus: the western Himalayas or Zanskar or Bara Lacha range, the mid-Himalayas or Pir Panj range, and the outer or sub-Himalayas. From these three great ranges spring numerous minor ranges, as ribs from a backbone, the whole forming a confused system of mountain chains and valleys, the breadth of which is some 90 m. at its eastern extremity from Lahul to the Siwalks of Hosharpur, and some 150 m. measured at its western extremity across Kashmir.

The Five Rivers. The “five rivers” of the Punjab are each of large volume; but, on account of the great width of sandy channel in their passage through the plains, their changing courses, and shifting shoals, they are of no value for steam navigation, though they all support a considerable boat-traffic. Of recent years most of them have been utilized for purposes of irrigation, and have turned the sandy desert of

1 Tuliis, in juridical Latin, the abstract noun from talis, such, alike, hence “retaliation.” See Exod. xx. 24; Lev. xxiv. 20; Deut. xix. 21.

2 This idea combined with the retributive is found as early as Deut. xix. 20: “And those which remain shall hear and fear, and shall henceforth commit no more any such evil.”
the Punjab into one of the great wheat fields of the British Empire.

While the general name Punjab is applied to the whole country of the "five rivers," there are distinct names for each of the doabs (do, two; ab, water) or tracts between two adjoining rivers. The country between the Sutlej and the Beas is called the Jullundur Doab; it includes the districts of Jullundur and Hoshiarpur. The long strip between the Beas and the Ravi, containing the greater part of Gurdaspur, Amritsar, Lahore, Montgomery, and Multan districts, is called the Bari Doab. Rechana Doab is the tract between the Ravi and the Chenab, embracing Sialkot and Gujranwala districts, with the trans-Ravi portions of the districts of the Bari Doab. Chaj or Jech is the doab between the Chenab and the Jhelum (Gujrat and Shahpur districts and part of Jhang), and Sind, Sagar is the name of the large doab between the Jhelum and the Indus, including Rawalpindi, Jhelum and Muzafergarh districts, with parts of Shahpur, Bannu and Dera Ismail Khan. The higher and dryer parts of the doabs are called bar. They are waste, but not barren, scantily covered with low shrubs, and capable, when watered, of being well cultivated. The bar is the great camel-grazing land. Large areas of Muzaffargarh and Multan districts are Bhal, barren tracts of shifting sand. The middle part of the Bari Doab, in Amritsar district, bears the distinctive name of Manjha (middle) as the centre and headquarters of the Sikh nation, containing their two sacred tanks of Amritsar and Taran Taran. The Malwa Sikhs, again, are those of the cis-Sutlej country.

South of the Himalayas stretch the great plains, which constitute by far the larger proportion of the province. With the exception of the Himalayan and Salt range tracts the Punjab presents, from the Jumna on the east to the Sullumans in the west, one vast level, unbroken save by the wide eroded channels within which the great rivers have filled their beds, by the insignificant spurs of the Aravalli range in the south-eastern corner, and the low hills of Chiniot and Kirana in Jhang. The whole of these vast plains is of alluvial formation. Stones are unknown save at the immediate foot of the hills; micaceous river sand is to be found everywhere at varying depths; and the only mineral is nodular accretions of limestone, called kankar, which is used for the construction of roads. The soil is a singularly uniform loam, the quality being determined by the greater or smaller proportion of sand present. In the local hills and drainage lines the constant deposit of argillaceous particles has produced a stiff tenacious soil, especially adapted to rice cultivation, while in the beds of the great rivers, and on the wind-fretted water-sheds pure sand is commonly found. Where neither sand nor the saline efflorescence called rh is present, the soil is uniformly fertile, if only the rainfall be sufficient or means of irrigation be available. Throughout the greater part of the western plains, however, the insufficiency of rainfall is a perpetual menace. The upland part of the country was that of wide steppes of intrinsically fertile soil, useful, however, only as grazing grounds for herds of camels or cattle.

The Punjab may be divided into four great natural divisions: the Himalayan track, the submontane tract, the eastern and western plains and the Salt range tract, which have characteristics widely different from each other. The Himalayan track, which includes the Punjab Himalayas, consists of 20,000 sq. m. of sparsely inhabited mountain, with tiny hamlets perched on the hillsides or nestling in the valleys. The people consist chiefly of Rajputs, Kandals, Girdharis, Brahmans and Urdu speaking people. The western part of the track, from each other by a line passing through Lahore, are dissimilar in character. The eastern are arable plains of moderate rainfall and almost without rivers, except along their northern and eastern edges. The Himalayan track, which includes the Punjab Himalayas, the great cities of Delhi, Amritsar and Lahore. They formed, until the recent spread of irrigation, the most fertile, wealthy and populous portion of the province. The western plains, except where canal irrigation has been introduced, consist of arid pastures with scanty rainfall, traversed by the five great rivers, of which the broad valleys alone are cultivable. They are inhabited largely by Mohammedan tribes, and it is in this tract that irrigation has worked such great changes. The Chenab and Jhelum Canal colonies are already pronounced successes, and it is hoped that in process of time the Lower Bari Doab and the Sind-Sagar Doab will be similarly improved. The numerous mineralized beds, especially of coal, in the salt range, has an area of 10,000 sq. m., consisting of some of the most fertile and thickly populated portions of the province. Its population comes midway between the peoples of the hills and of the plains in hair, dress, complexion and language. The Muslims and Hindus have more in common than either has with the Moghuls or the British. The former are generally more spoken, and Rajput and hill menials more common than in the plains. The Gujars form a special feature of this zone. Its only large town is Sialkot. The Salt range tract includes a district of Rawalpindi and Jhelum and a small portion of Shahpur district, and consists of some 9000 sq. m. of broken and confused country.

Geology.—By far the greater part of the Punjab is covered by alluvial and wind-blow deposits of the plain of the Indus. The silts and sands of the Indus and its tributaries are distributed over the whole plain. The deposits of sand and gravel, which have been formed and spread by the wind, are found in a very strong position, in spite of the lapse of time which it indicates. At the bottom of the Carboniferous series there is usually a boulder bed, the boulders of which have been brought from a distance and are frequently of granite or of schist. Between them is a clay, but very strongly marked, in spite of the lapse of time which it indicates. There are various other deposits of clay in other parts of the peninsula, in Australia and in South Africa, indicating a southern glacial period in late Carboniferous times. Above the sandstones the beds at times dip at an angle of 90°, the bottoms of which the boulders have been washed away, and thus the Productus and Carstite limestones. The former is believed to belong to the Upper Carboniferous and Permain, the latter to the Trias. Jurassic beds are found only in the western portion of the range.

Climate.—Owing to its sub-tropical position, scanty rainfall and cloudless skies, and the wide expanse of untilled plains, the climate of the Punjab presents greater extremes of both heat and cold than can be found on any other part of the continent. Between the middle of September and the middle of March it is extremely hot, while from the beginning of October to the end of March there is a magnificent cool season, resembling that of the Riviera, with warm bright days and very cold nights. The first three months of the hot season, from April till the end of June, a dry heat is experienced, with a temperature rising to 120° F. in the shade. At the end of June the monsoon arrives, the rains break, and though the heat is less intense the air is moist, and from the middle of August the temperature gradually falls. This is the most unhealthy period of the year, being exceedingly malicious. The Punjab enjoys two well-marked seasons of rainfall; the monsoon period, lasting from the middle of June till the middle of September, and the winter period. The rains depend upon the extent of the south-west monsoon, which becomes exhausted in its passage over the great plains of Sind and Rajputana, while the west winds from Baluchistan pass over and are lost. The climate of the plains is often described as a perpetual summer; this is true of the upper parts of the Indus Valley, and of the western portion of the Punjab, but the climate is never so oppressive as in the Doab below the Jhelum and the Indus. The rains are everywhere abundant, and the most unhealthy periods are during the months of June and July. The climate of theSalt range is a perpetual winter. The cold is intense, and the snow of the Himalayas melts only in late April or early May.
cultivation in Kashmir has been more encouraging. Potatoes are grown extensively on cleared areas on the hills. The Punjab produces freely many of the Indian grapes. Grapes are grown in many of the Himalayan valleys where the rain is not so excessive; but much of the fruit is lost through the heat and the original beds. The greater the forests are the deciduous (Cedrus Deodara) and chill (Pinus longfolia) trees in the hills, the plantations of shisham (Dalbergia Sissoo) and sal (Shorea robusta) in the plains, and the fuel raths or preserves (Akaan) in the tracts.

Manufactures.—Most of the native manufactures of the Punjab are those common to other parts of India, such as the mahogany, plain woollen blankets, unglazed pottery, ropes and cord, grass matting, paper, leather-work, brass vessels, simple agricultural implements, and the like, useful in the tracts. Other manufacturing products, not so general, yet not peculiar to the Punjab, are woollen fabrics, carpets and shawls, silk cloths and embroidery, jewelry and ornamental metal-work, wood and ivory carving, turned and lacquered woodwork, glazed pottery, arms and armours, and musical instruments. But some of these classes of manufactures are represented by work of special kinds or special excellence in particular parts of the Punjab, notably the silk fabrics of Multan and Bahawalpur; the cotton cloths, of Lahore and Amritsar; the khatam or glazed woodwork (an ancient art still practised in a few places); koji-kari, inlaid metal-work (gold wire on steel), chiefly made at Gujrat and Sialkot; shawls and other fine woolen fabrics, made by Kashmiri workmen, and in the North-West Frontier Provinces; and the embroidery for shawls, scarfs and turbans, at Delhi, Lahore and Multan; embroidery on cloth for elephant-trappings, bed and table covers, &c, at Lahore and Multan; enamelled ornaments, in Lahore; and the muzzull emblems, held by the Cawal Of Simla; lacquered woodwork, at Pak Pattan. Cotton-weaving gives employment to about a million persons, but the most flourishing industry is the woolen factories of Amritsar, Gurdaspur and elsewhere. The sugar industry is the great one of the Punjab, as of other parts of India, by unwise copying of European patterns. The Lahore School of Art attempts to correct this and promote the study and execution of native forms and designs. The Lahore Museum contains a collection of the finest manufactured articles, as well as raw products, of the Punjab; and also a large collection of the sculptures, mostly Buddhist, and many of Greek workmanship, found in the north-west of the province.

Trade.—The prosperity of the Punjab is almost wholly dependent upon agriculture. In a normal year the principal feature of the trade is the movement of wheat to Karachi, which is the chief port for the province. But in a bad season, when the rains fail, this movement is at once checked, the wheat is held in reserve and the export is very small. In 1905-1906, 323 million maunds of wheat were exported, but 1905 was a bad season and the amount fell to 21 million maunds. The other chief articles of export are raw wool and raw cotton. The chief imports are rice, sugar, jute, wood, tea, iron, cotton goods, cotton piece-goods, sugar, metals and jute goods. The trade in the main staples of grain and piece-goods is in the hands of the largest European and native firms. In addition to the foreign trade there is a commerce between the United Provinces, and with the United Provinces and the United Provinces, and with the Trans-frontier trade with Kashmir, Ladakh, Yarkand and Tibet on the north, and with Afghanistan on the west.

Irrigation.—Irrigation for large areas is from canals and from reservoirs, and for smaller areas from wells. The canals are of two kinds; those carrying a permanent stream throughout the year, and those which fill only on the periodical rising of the rivers, the latter being known as "imperadon canals." There are only a few examples in the country using facilities for forming reservoirs, by closing off the natural streams and allowing them to be filled with such rainfall. The old canals made by the Mohamadun rulers, of which the principal are Feroz's Canal from the Jumna and the Hadi Canal from the Kali, have been improved or reconstructed. Of the new irrigation canals the principal are those on the Sindh, drawn from the Sutlej near Rupar, which irrigates parts of the native states of Patiala, Nabha and Jhinda, as well as British territory; the Bari Doab Canal from the Kali; the Chenab Canal (the prosperous Chenab colony); and the Jhelum Canal irrigating the Jhelum colony. The total area irrigated by the canals of the province in 1905-1906 was 8,914,500 acres, the eight major works, the Western Jumna, Bari Doab, Chenab, Hadi Kali, Sutlej, Beas, Jhelum, and the Tawi, contributing 7,477,000 acres, the Sindh and Indus accounting for all but 751,000 acres. The ravages of the boll-worm in the cotton crop made 1906 an unfavourable year, but in spite of that the Lower Chenab Canal paid nearly 21% on capital borrowed, the Bari Doab 17% and the Western Jumna nearly 10%.

Railways.—The Punjab is well supplied with railways, which have their central terminus at Delhi. One main line runs from Umballa through Lahore and Rawalpindi towards Peshawar; another main line runs from Lahore to Multan, and thence to the sea at Karachi; while a third runs along the line between the Indus, from Attock southwards. From Delhi to Umballa there are two lines, one of the North-Western through Meerut and Safarpan in the United Provinces, and a more direct route which connects to Kali. A short line runs to the hills, whence a further continuation to Simla has been opened. The south-east of the province is served by two branches of the Rajputana system, which have their termini at Delhi and Ferozepore; and also by the Southern Punjab, which runs from Delhi to Bahawalpur.

Population.—The total population of the Punjab (including native states) according to the census of 1901 was 24,754,737, showing an increase of 6.4% in the decade. The Jats, who number some five millions, form the backbone of the cultivating community. Large numbers of them have become Sikhs or Mahommedans in the tracts where those religions predominate. The Rajputs, with a total of over a million and three-quarters, comprise tribes of different religions, races and social systems. By religion they are mostly Mahommedan, only about one-fourth being Hindus, while a very few are Sikhs. By race they include the ancient ruling tribes of the Jumna valley, the Tomar and Chauhan, which gave Delhi its most famous Hindu dynasties; the Bhatis of the south and centre, which have migrated from Bikanir and Jeyulsore into their present seats; the Sial of Jhang; and the Punwars of the south-west. In the northern or submontane districts the Rajputs also represent the old ruling tribes, such as the Chibbs of Gujrat, the Januas of the Salt range and others, while in Kangra district they preserve a very old type of Hindu aristocracy. The Gujars are an important agricultural and pastoral tribe. They are most numerous in the eastern half of the province and in the districts of the extreme north-west, especially in Gujrat, to which they have given their name. Baluchis and Pathans are strongly represented in the south-west. The distinctive religion of the Punjab is Sikhism (q.v.), though Sikhs form only 8% of the total population. Of the rest, Mahomedans are more numerous than Hindus.

Language.—Of the 24,754,737 people in the Punjab about 18,000,000 speak the principal language, Punjabi, which varies in character in different parts of the province. About 4,000,000 speak Hindustani (see HINDOSTANI), this number including those whose ordinary vernacular is Hindi, but who understand and are gradually adopting the more comprehensive Hindustani. These two languages are the most generally used throughout the province, but not equally in all parts. The other languages in use are more or less local. The hill dialects, known as Pahari, are akin to the language spoken in Rajputana; and so also is the speech of the Gujars. Hindustani is the language of the law courts and of all ordinary officials and other communications with chiefs and people.

Administration.—The administration is conducted by a lieutenant-governor, who is appointed by the governor-general, subject to the approval of the Crown. Two commissioners take the place of the provincial council in the other provinces. A system of the "crown regulations" is to be found in the title of deputy-commissioner for the district officer elsewhere called collector. The highest judicial authority is styled the chief court, consisting of five judges, which corresponds to the high court elsewhere. A legislative council, first created in 1857, was enlarged in 1900 to 26 members, of whom ten are officials and five are elected. The province is distributed into five divisions or commissionerships. Most of the commissioners also exercise political functions over the native states within their jurisdiction.

Education.—The Punjub University, which was founded in 1882, differs from other Indian universities in being more than a merely examining body. It is responsible for the management of the Oriental College at Lahore, and takes part in the improvement of vernacular literature. It also conducts Oriental examinations side by side with those in English, and has been the first to introduce a series of examinations in science from matriculation to the degree, as well as a final school examination in clerical and commercial subjects. The higher and special educational institutions are the Lahore Government College, the Cambridge
University Mission College at Delhi, the Medical School and the Mayo School of Art at Lahore; and the Punjab Chiefs' College, also at Lahore.

History.—For the early history of the Punjab from the Aryan immigration to the fall of the Mogul dynasty see India: History. It deserves, however, to be noted here that from the time of Alexander onwards Greek settlers remained in the Punjab, and that Greek artists gave their services for Buddhist work and introduced features of their own into Indian architecture. Besides the bases and capitals of large Greek columns at Shahderi (Taxila) and elsewhere, numerous sculptures of Greek workmanship have been found at various places. These are single statues (probably portraits), also figures of Buddha, and representations of scenes in his legendary history, and other subjects. They are obtained from ruins of monasteries and other buildings, from mounds and the remains of villages or monumental tobes. Of Buddhist buildings now remaining the most conspicuous as well as distinctive in character are the tobes (stupa), in shape a plain hemisphere, raised on a platform of two or more stages. One of the largest of these is at Manikiala, 14 m. east of Rawalpindi. These Buddhist buildings and sculptures are all probably the work of the two centuries before and the three or four after the beginning of the Christian era. The character of the sculptures is now well known from the specimens in the India Museum, South Kensington, and both originals and casts of others in the Lahore Museum. Unfortunately they have no names or inscriptions, which give so much value to the sculptures of the Bharhut tope.

The several bodies of settlers in the Punjab from the earliest times have formed groups of families or clans (not identical with Indian castes, but in many cases joining them), which have generally preserved distinct characteristics and followed certain classes of occupation in particular parts of the country. Some of the existing tribes in the Punjab are believed to be traceable to the early Aryan settlers, as the Bhatti tribe, whose special region is Bhattiana south of the Sutlej, and who have also in the village of Pindi Bhattian a record of their early occupation of a tract of country on the left bank of the Chenab, west of Lahore. The Dogras, another Aryan clan, belong to a tract of the lower hills between the Chenab and the Ravi. Others similarly have their special ancient localities. To the earlier settlers—the dark race (Dasyu) whom the Aryans found in the country, and who are commonly spoken of as aborigines—belonged, as is supposed, the old tribe called Takka, whose name is found in Taksha-sila or Taxila. And from the later foreigners again, the Indo-Scythians, are probably descended the great Jat tribe of cultivators, also the Gugars and others.

It was during the events which brought Baber, the first of the Mogul dynasty, to the throne, that the sect of the Sikhs was founded by Nanak; and it was under the persecution of Aurangzeb that they were raised into a nation of warriors by Govind Singh, the tenth and last of the gurus. For their tenets and history see Sikhism.

The break-up of the Mogul Empire in the 18th century allowed the Sikhs to establish themselves, as a loosely organized community of marauders, in the eastern plains of the Punjab, on both banks of the Sutlej. Here, after long intermecine warfare, one of their chiefmen succeeded in enforcing his authority over the rest. This was Ranjit Singh, the "Lion of the Punjab," born in 1780, who acquired possession of Lahore as his capital in 1799. Ranjit was a man of strong will and immense energy, of no education but of great acuteness in obtaining the knowledge that would be of use to him. When he endeavoured to include the Sikh states south of the Sutlej within his jurisdiction, the heads of these states—chiefs of Sirhind and Malwa, as they were called—sought and obtained in 1808 the protection of the British, whose territories had now extended to their neighbours. The British were at this time desirous of alliance with Lahore as well as with Kabul, for protection against supposed French designs on India. A British envoy, Charles Metcalfe, was received by Ranjit at Kasur in 1809 and the alliance was formed. Ranjit steadily strengthened himself and extended his dominions.

In 1809 he got possession of Kangra, which the Nepalese were besieging. In 1813 he acquired the fort of Attock on the other side of the Punjab; and in the same year he obtained from Shah Shuja, now a refugee in Lahore, what he coveted as much as territory, the celebrated Koh-i-nor diamond, which had been carried off by Nadir Shah from Delhi. In 1818, after some failures in previous years, he captured Multan. Kashmir, which had successfully opposed him several times, was annexed the following year, and likewise the southern part of the country between the Indus and the hills. The Peshawar valley he succeeded in adding four years later, but he found it best to leave an Afghan governor in charge of that troublesome district. These trans-Indus and other outlying tracts were left very much to themselves, and only received a military visit when revenue was wanted. Peshawar was never really ruled till Avitaible was sent there in later years. When he was gradually raising his large and powerful army Ranjit received into his service certain French and other officers, who drilled his troops and greatly improved his artillery. Whilst he relied on these foreigners for military and sometimes also for administrative services, he drew around him a body of native ministers of great ability, of whom the brothers Gulab Singh and Dhian Singh of Jammu were the most influential.

Ranjit always maintained friendly relations with the British government, and just before his death gave tacit approval to the scheme for placing Shah Shuja on the throne of Kabul. His death in 1839 was followed by six years of internal anarchy, princes and ministers being murdered in quick succession, while all real power passed to the army of 50,000 trained troops. At last this army, unpaid and unmanageable, demanded to be led into British territory, and had their way. They crossed the Sutlej in December 1845. The battles of Moodkee, Ferozeshah and Aliwal were followed by the rout of the Sikh army at Soobraon on the 10th of February 1846, when they were driven back into the Sutlej with heavy loss, and the British army advanced to Lahore. Of the Sikh guns 256 fell into the hands of the British in these actions on the Sutlej. A treaty was made at Lahore on the 9th of March with the chiefs and ministry who were to hold the government on behalf of the young maharaja, Duleep Singh. By this treaty the Jullundur Doab and the hill district of Kangra were ceded to the British, also the possessions of the maharaja on the left bank of the Sutlej. In addition the British demanded a money payment of £1,500,000. The services of Gulab Singh, raja of Jammu, to the Lahore state, in procuring the restoration of friendly relations with the British, were specially recognized. His independent sovereignty in such lands as might be made over to him was granted. The Sikh government, unable to pay the whole of the money demand, further ceded, as equivalent for £1,000,000, the hill country between the Beas and the Indus, including Kashmir and Hazara. Gulab Singh was prepared to give the amount in place of which Kashmir was to have become British, and by a separate treaty with him, on the 18th of March 1846, this was arranged. At the request of the British, Ranjit Singh, who was left at Lahore for the protection of the maharaja and the preservation of peace, to restore order and introduce a settled administration a British resident was appointed, who was to guide and control the council of regency, and assistants to the resident were stationed in different parts of the country.

Peace was not long preserved. The governor of Multan, Diwan Mulraj, desired to resign. Two British officers sent by the resident to take over charge of the fort were murdered, on the 19th of April 1848, and their escort went over to the diwan. Another of the assistants to the resident, Lieutenant Herbert Edwardes, then in the Derajat, west of the Indus, on hearing of their fate, collected a force with which to attack the Multan army while the insurrection was yet local. This he did with signal success. But Multan could not fall before such means as he possessed. The movement spread, the operations widened, and the Sikh and British forces were in the field again. Multan was taken. The severe battle of Chillianwalla on the 13th of January 1849 left the Sikhs as persistent as after the two terrible
days of Ferozeshah in the previous campaign. And it needed the crushing defeat of Gujrat, on the 21st of February 1849, to bring the war to a conclusion, and this time to give the Punjab to England. It was annexed on the 2nd of April 1849.

For the government of the new province, including the Jullundur Doab, previously annexed, and the cis-Sutlej states, a board of administration was appointed consisting of three members. In place of this board a chief commissioner was appointed in 1853, aided by a judicial commissioner and a financial commissioner. British troops, European and native, of the regular army were stationed at the chief cities and other places east of the Indus and at Peshawar. For the rest of the trans-Indus territory a special body of native troops, called the Punjab frontier force, was raised and placed under the orders of the chief commissioner. During the Mutiny of 1857 the Punjab, under Sir John Lawrence as chief commissioner, was able to send important aid to the force engaged in the siege of Delhi, while suppressing the disturbances which arose, and meeting the dangers which threatened, within the Punjab itself. In 1858 the Delhi territory, as it was called, west of the Jumna, was transferred from the North-Western Provinces to the Punjab. The enlarged province was raised in rank, and on the 1st of January 1859 the chief commissioner became lieutenant-governor. In 1901 the frontier districts beyond the Indus were severed from the Punjab and made into a separate province called the North-West Frontier province.

Innes, The Sikhs and their Wars (1897); Professor R. G. B. Life of Lord Gough (1903); Mahomet Latif, History of the Punjab (Calcutta, 1891); and Punjab Gazetteer (2 vols., Calcutta, 1908).

PUNKAH (Hindostani ānkha), strictly a fan. In its original sense the punkah is a portable fan, made from the leaf of the palmyra; but the word has come to be used in a special sense by Anglo-Indians for a large swinging fan, fixed to the ceiling, and pulled by a coolie during the hot weather. The date of this invention is not known, but it was familiar to the Arabs as early as the 8th century, though it does not seem to have come into common use in India before the end of the 18th century. Of recent years it has largely been supplanted by the electric fan in barracks and other large buildings.

PUNSHON, WILLIAM MORLEY (1824–1881), English Non-conformist divine, was born at Doncaster, Yorkshire, on the 29th of May 1824. He was educated in his native town, and, after spending a few years in business, at the Wesleyan College, Richmond. In 1845 he received his first appointment, at Malham, Kent, and soon became famous as a preacher. After serving the usual period of probation he was ordained at Manchester in 1849 and for the next nineteen years travelled in several circuits, including some of the London ones (1856–1864). In 1868 he went to Chicago as the representative of the Wesleyan Methodist conference, and settling in Canada did much to advance the cause of his denomination. His preaching and lecturing drew great crowds both in the Dominion and in the United States, and he was five times president of the Canadian conference. He returned to England in 1873, was elected president of conference 1874, and in 1875 one of the missionary secretaries. He published several volumes of sermons, and a book of verse entitled Sabbath Chimes (1867, new edition 1886).

PUNT (from Lat. ponto, pontoon; connected with pons, bridge), a flat-bottomed boat, used for shallow waters, and propelled by punt or by poles. Formerly the word was applied to many such flat boats used for ferries, barges, lighters, &c., but it is now generally confined to a light flat boat very long in proportion to its width, with square ends, both at stem and bow, slightly narrowing from the centre, and propelled by pushing against the bottom of the river or other water by a long pole. Such boats are much used for sport or pleasure on rivers with shallow and hard gravelly beds; a small punt with a mounted duck gun and propelled by paddles or short oars is used for wild-fowling. A professional punting championship of England was instituted in 1876, and an amateur championship in 1886. Etymologically considered, “punt” certainly was adapted from ponto, a word used by Caesar (Bell. civ. iii. 22) of a light vessel for transport in Gaul. Later (as by Gallus and Ausonius) it was also applied to a floating-raft used as a bridge, a pontoon, and so connected with pons, bridge.

There are two other words which must be distinguished from the above, namely, punt and pun, both of which are used in the hands, drop and kick it before it reaches the ground, as distinguished from a “drop-kick,” where the kick is given half- volley, as it reaches the ground. This word is probably cognate with “bunt,” a dialectal word meaning to push, and both represent nasalized forms of the onomatopoeic “put” or “but.” The second, in the substantive “punter,” used in the general sense of a gambler or better, originally referred to one who at card games such as basset, baccarat, &c., stakes against the bank on both “punt” and “punter” to be referred to Fr. ponte, and ponte, which is usually taken as an adaptation of Span. panto, a point.

PUNTARENAS, or PUNTA ARENAS, a seaport and capital of the district (comarca) of Puntarenas, Costa Rica; on the Gulf of Nicoya, an inlet of the Pacific Ocean, and at the western terminus of the interoceanic railway from Limón. Pop. (1904), 3569. Puntarenas is the principal harbour of Costa Rica on the Pacific, and a port of call for the United States liners which ply between San Francisco and Panama. It has an iron pier and ample warehouse accommodation for its large and growing export trade in coffee and bananas. The district of Puntarenas comprises the entire littoral from Burica Point to the Rio de las Lajas, an affluent of the Gulf of Nicoya.

PUPIL (Lat. pupillus, orphan, minor, dim. of pupus, boy, allied to prec, from root pu- or pu-, to beget, cf. "pup," Lat. for "doll," the name given to the stage intervening between the larval and imaginal stages in certain insects), properly a word taken from Roman law, for one below the age of puberty (im- pulses), and not under patera potestas, who was under the protection of a tutel, a ward or minor (see Infant; and Roman Law). The term was thus taken by the Civil Law and Scots Law for a person of either sex under the age of puberty in the care of a guardian. Apart from these technical meanings the word is generally used of one who is undergoing instruction or education by a teacher. In education the term “pupil-teacher” is applied to one who, while still receiving education, is engaged in teaching in elementary schools. The system was introduced into England from Holland about 1840. At first the education which the pupil-teachers received was given at the schools to which they were attached. During the last quarter of the 19th century was developed a system of “pupil-teacher centres” where training and education was given. In 1907 was introduced “bursaries,” as an alternative; these enable those intending to become teachers to continue their education at training colleges or selected schools as “student teachers.” (See EDUCATION.)

A special use of the Lat. feminine diminutive pūpilla has been adopted in English and other languages for the central orifice in the iris of the eye, the pupil. The origin of the sense may be found in the parallel use in early English of “baby,” referring to small images seen reflected in that part of the eye (see Eye and Vision).

PURBECKIAN, in geology, the highest and youngest member of the Jurassic system of rocks. The name is derived from the district known as the Isle of Purbeck in Dorsetshire where the strata are splendidly exposed in the cliffs west of Swanage. The rocks include clays, shales and marls with marly, tuffaceous and shelly limestones and occasional oolitic and sandy strata. Nodules of chert are present in some of the limestones. The Purbeck beds follow the line of the Jurassic outcrop from Dorsetshire, through the Vale of Wardour, Swindon, Garsington, Brill and Aylesbury; they have been proved by borings to lie beneath younger rocks in Sussex; in Lincolnshire they are represented in part by the Spilsby Sands, and in Yorkshire by portions of the Speeton Clay. The thickness of the series in Wiltshire is 80 to 90 ft., but in Dorsetshire it reaches nearly 400 ft. In most places the Purbeckian rests conformably upon
the Portland beds and it is conformably overlaid by the Wealden formations; but there are in some districts distinct indications that the Portland rocks were uplifted and worn to some extent prior to the deposition of the Purbeck beds. The Purbeckian in England is divisible into three subdivisions, viz. Upper, Middle and Lower. The Upper Purbeck comprises 50-60 ft. of fresh-water clays and shales with limestones, the "Purbeck marble" and *Unio*-bed, in the lower part. The Middle division (50-150 ft.), mainly thin limestones with shaly partings, contains the principal building stones of the Swanage district; near the base of this subdivision there is a 5-in. bed from which an interesting suite of mammalian remains has been obtained; in this portion of the Purbeck series there are some marine bands. The Lower Purbeck (95-160 ft.) consists of fresh-water and terrestrial deposits, marls, and limestones with several fossil soils known as "dirt beds." This division is very extensively exposed on the Isle of Portland, where many of the individual beds are known by distinctive names. The chief building stones of Upway belong to this part of the Purbeckian.

No zonal fossil has been recognized for the British Purbeckian strata, but the horizons of the Middle Purbeck appear to have been of great importance in the study of the eurypterid *Eurypterus remipes* and the fossil *fossiliferous slates* of the Lower Jurassic. The Purbeckian equivalents of Spilsby and Speeton are in the zone of *Belomelittes lateralis*. Other marine fossils are *Hemicardites purbeckensis* and *Ostracodus stanimori*, the latter being abundant in the "Cinder Bed" of the Middle Purbeck; fresh-water fossils include *Vinparus* (P. Palmater), *Planorbis*, *Melanopsis*, *Unio*, *Cyrena*. A large number of insect genera has been found in the Middle and Lower Purbeck beds. Dinosaurs (*Iguanodon, Echinodon*), crocodiles (*Gomphosuchus*, *Pseudosuchus*), turtles (*Testudinella*), titanothere (*Srealodon*), *Chelone*, *Cleidostoma* (the crustacean *Arthropod*), are representative reptiles. The mammals, mostly derived from lower jaws, found in the beds mentioned above include *Pliology*, *Aphelotherium*, *Stylon*, *Triodon*, *Spindothorax*, and several others. The isolated crustacean *Arthrocystis Brodiei is very common in the Purbeck of the Vale of Wardour. The siliquid stumps and trunks of cycads and coniferous trees, often surrounded by great masses of calcareous concretions (*Burns*), are very characteristic of the dirt beds found at the head of the Purbeck. Chara is found in the fresh-water cherts of the Middle Purbeck.

Many geologists have ranged the Purbeck beds with the overlying Wealden formation on account of the similarity of their fresh-water fauna; but the marine fossils, including the fishes, ally the Purbeck more closely with the Upper Jurassic rocks of other parts, and it may be regarded as the equivalent of the Upper Volgan of Russia. The Purbeckian is present in the neighbourhood of Boulogne; in Cherbourg it was worked by *Cherbourg* and in the Hohne as *Hohne* and in the Krems. Chara is found in the fresh-water chert of the Middle Purbeck.

The building stones of the Purbeck beds have already been mentioned: the Purbeck or Paleudina marble, a grey or greenish limestone full of shells, was formerly extensively employed in cathedrals and churches. Stone tiles or "slats" were once used locally for roofing from the Lower Purbeck of Portland, Swanage and Swindon. Chara, which was formerly worked from the Lower Purbeck at Swanage, is extensively used for building. Chara is an important rock in the Purbeck of great size and is extensively used for building. Chara is an important rock in the Purbeck of great size and is extensively used for building. Chara is an important rock in the Purbeck of great size and is extensively used for building. Chara is an important rock in the Purbeck of great size and is extensively used for building.

**See JUSSARIS; also The Jurassic Rocks of Great Britain (1865), vol. v. and "The Geology of the Isle of Purbeck and Weymouth," Memoirs of the Geol. Survey (1868).**

**PURCELL, HENRY** (1655-1695). English musical composer, was born in 1658 in St Ann's Lane, Old Pye Street, Westminster. Of his father, Henry Purcell (or Puscell), was a gentleman of the chapel-royal, and in that capacity sang at the coronation of Charles II.; he had three sons, Edward, Henry and Daniel— the last of whom (d. 1717) was also a prolific composer. After his father's death in 1664 young Henry Purcell was placed under the care of the countess of Oxford, a lady of extraordinary probity and kindness. Through the interest of this affectionate guardian, who was himself a gentleman of His Majesty's chapel, Henry was admitted to the chapel-royal as a chorister, and studied first under Captain Henry Cooke (d. 1672), "master of the children," and afterwards under Pelham Humfrey (1647-1674), his successor, a pupil of Lully. He is said to have composed well at nine years old; but the earliest work that can be certainly identified as his is an ode for the king's birthday, written in 1670. (The dates for his compositions are often uncertain, though recent research has done much to fix them more authoritatively.) After Humfrey's death he continued his studies under Dr John Blow. In 1676 he was appointed copyist at Westminster Abbey—not organist, as has sometimes been erroneously stated—and in the same year he composed the music to Dryden's *Aurigne-Zele*, and Shadwell's *Epsom Wells* and *The Libertine.* These were followed in 1677 by the music to Mrs Behn's tragedy, *Abdelazer,* and in 1678 by an overture and masque for Shadwell's new version of Shake-peare's *Timon of Athens.* The excellence of these compositions is proved by the fact that they contain songs and choruses which never fail to please, even at the present day. The masque in *Timon of Athens* is a masterpiece, and the chorus "In these delightful pleasant groves" in *The Libertine* is constantly sung with applause by English choral societies. In 1679 he wrote some songs for Playford's *Choice Ayres, Songs and Dialogues,* and also an anthem, the name of which is not known, for the chapel-royal. From a letter written by Thomas Purcell, and still extant, we learn that this anthem was composed for the exceptionally fine voice of the Rev. John Gostling, then at Canterbury, but afterwards a gentleman of His Majesty's chapel. Purcell wrote several anthems at different times for this extraordinary voice, a *basso profundo,* the compass of which is known to have comprised at least two full octaves, from D below the A-bass to F above the tenor-a-fist. The music to these four compositions is known; but one, "They that go down to the sea in ships," though certainly not written until some time after this period, will be best mentioned here. In thankfulness for a providential escape of the king from shipwreck Gostling, who had been of the royal party, put together some verses from the Psalms in the form of an anthem, and requested Purcell to set them to music. The work is a very fine one but very difficult, and contains a passage which traverses the full extent of Gostling's voice, beginning on the upper D and descending two octaves to the lower.

In 1680 Dr Blow, who had been appointed organist of Westminster Abbey in 1669, resigned his office in favour of his pupil; and Purcell, at the age of twenty-two, was placed in one of the most honoured positions an English artist could occupy. He now devoted himself almost entirely to the composition of sacred music, and for six years entirely severed his connexion with the theatre. But during the early part of the year, and in all probability before entering upon the duties of his new office, he had produced two important works for the stage, the music for Lee's *Theodosius* and D'Urley's *Virtuous Wife.* The composition of his opera *Dido and Aeneas*, which forms a very important landmark in the history of English dramatic music (see OPERA), has been attributed to this period, though its earliest production has been shown by Mr W. Barclay Squire to have been between 1688 and 1690. It was written to a libretto furnished by Nahum Tate, at the request of Josiah Priest, a professor of dancing, who also kept a boarding-school for young gentlemen, first in Leicester Fields and afterwards at Chelsea. It is a musical drama in the strictest sense of the term, a genuine opera, in which the action is entirely carried on in recitative, without a word of spoken dialogue from beginning to end; and the music is of the most genial character— a veritable inspiration, overflowing with spontaneous melody, and in every respect immensely in advance of its age. It never found its way into the theatre, though it appears to have been very popular among private circles. It is believed to have been extensively copied, but one song only was printed by Purcell's widow in *Orpheus Britannicus,* and the complete work remained in manuscript until 1848, when it was printed by the Musical Antiquarian Society, under the editorship of Sir George Macfarren.

In 1682 Purcell was appointed organist of the chapel-royal, vice Edmund Lowe deceased, an office which he was able to hold conjointly with his appointment at Westminster Abbey. He had recently married, his eldest son being born in this year. His first printed composition, *Twelve Sonatas,* was published in 1684. For some years after this his pen was busily employed in the production of sacred music, odes addressed to the king and royal family, and other similar works. In 1685 he wrote two
of his finest anthems. "I was glad" and "My heart is inditing," for the coronation of James II. In 1687 he resumed his connex-

on with the theatre by furnishing the music for Dryden's
tragedy, Tyrannic Love. In this year also Purcell composed a

march and quick-step, which became so popular that Lord
Wharton adapted the latter to the fatal verses of Lilliburlero;

and in or before January 1688 he composed his anthem "Blessed

are they that fear the Lord," by express command of the king.

A few months later he wrote the music for D'Urfey's play, The

Fool's Preferment. In 1690 he wrote the songs for Dryden's

version of Shakespeare's Tempest, including "Full fathom five" and

"Come unto these Yellow Sands," and the music for

Betterton's adaptation of Fletcher and Massinger's Prophetaes

(continues called Dioecesan), and Dryden's Amphitryon; and

in 1691 he produced his dramatic masterpiece, King Arthur,

also written by Dryden, and first published by the Musical

Antiquarian Society in 1843. In 1692 he composed songs and

music for The Fairy Queen (an adaptation of Shakespeare's

Midsummer Night's Dream), the score of which (discovered

in 1901) was edited in 1903 for the Purcell Society by

J. S. Shedlock. But Purcell's greatest work is undoubtedly his Te Deum and

Jubilate, written for St Cecilia's Day, 1664, the first English

Te Deum ever composed with orchestral accompaniment.

In this he pressed forward so far in advance of the age that the work

was annually performed at St Paul's Cathedral till 1712, after

which it was performed alternately with Handel's Utrecht Te

Deum and Jubilate until 1743, when it finally gave place to

Handel's Dettingen Te Deum. Purcell did not long survive the

production of this great work. He composed an anthem for

Queen Mary's funeral, and two elegies. He died at his house in

Dean's Yard, Westminster, on the 21st of November 1695, and

was buried under the organ in Westminster Abbey. He left a

widow and three children, three having predeceased him. His

widow died in 1706. She published a number of his works,

including the now famous collection called Orpheus Britannicus

(two books, 1698, 1703). Besides the operas already mentioned, Purcell wrote Don Quixote,

Bondoza, The Indian Queen and others, a vast quantity of sacred

music, and numerous odes, cantatas and other miscellaneous pieces.

(See the list in Grove's Dictionary of Music.)

A Purcell Club was founded in London in 1836 for promoting the

performance of Purcell's music, but was dissolved in 1863. In 1876

a Purcell Society was founded, which has done excellent work in

publishing new editions of his works.

PURCHASE, SAMUEL (1572-1626), English compiler of works

on travel and discovery, was born at Thaxted, Essex, and

graduated at St John's College, Cambridge, in 1600; later he

became B.D., with which degree he was admitted at Oxford in

1615. In 1604 he was presented by James I. to the vicarage of

Eastwood, Essex, and in 1614 became chaplain to Archbishop

Abbot and rector of St Martin's, Ludgate, London. He had

previously spent much time in London on his geographical work.

In 1613 he published Purchas, his Pilgrimage; or, Relations of the

World and the Religions observed in all Ages (4th ed. much

enlarged, 1626); in 1610 Purchas, his Pilgrim, Microcosmus,

or the histories of Man. Relating the wonders of his Generation,

vanities in his Degeneration, Necessity of his Regeneration; and in

1613 Hakluytus Posthumus or Purchas his Pilgrimes, containing a

History of the World in Sea Voyages and Lande Travells, by

Englishmen and Others (4 vols.). This continuation of Hakluyt's

Principal Navigations was partly based on Mss. left by Hakluyt.

The fourth edition of the Pilgrimage is usually catalogued as

vol. v. of the Pilgrimes, but the two works are essentially

different. Purchas died in September or October 1626, according
to some in a debtors' prison. None of his works was reprinted
till the Glasgow reissue of the Pilgrimes in 1905-1907. As an
editor and compiler Purchas was often injudicious, careless and

even unfaithful; but his collections contain much of value, and

are frequently the only sources of information upon important

questions affecting the history of exploration.

PURCHASE, in its common sense, that which is acquired

by the payment of money or its equivalent. The original

meaning of the word (O. Fr. pourchacier, pourchassier, etc., popular,

Lat. pro-capitale) was to pursue eagerly, hence to acquire. Thus

"purchase" was early used by the lawyers (e.g. Britton,
in 1293) for the acquisition of property by other means than

inheritance or mere act of law, including acquirement by

escheat, prescription, occupancy, alienation and forfeiture;

more generally, purchase in law means acquisition of land by

bargain or sale, according to the law of "vendor and purchaser"

(see CONVEYANCING). A later development of meaning is found

in the use of the word for a mechanical contrivance by which

power can be excited or applied, a hold or fulcrum. This first

appears (16th century) in the nautical use of the verb, to haul

up a rope or cable by some mechanical device, the root idea being

apparently to "gain" or "advantage" over the rope bit by bit.

PURGATORY (Late Lat. purgatorium, from purgere, to purge),

according to Roman Catholic faith, a state of suffering after

death in which the souls of those who die in venial sin, and of

those who still owe some debt of temporal punishment for

mortal sin, are rendered fit to enter heaven. It is believed that

such souls continue to be members of the Church of Christ; that

they are helped by the suffrages of the living—that is, by prayers,
alms and other good works, and more especially by the sacrifice

of the Mass; and that, although delayed until "the last

farthing is paid," their salvation is assured. Catholics support

this doctrine chiefly by reference to the Jewish belief in the

efficacy of prayer for the dead (2 Macc. xii. 42 seq.), the tradition

of the early Christians, and the authority of the Church.

Irenaeus regards as heretical the opinion that the souls of the

departed pass immediately to glory: Tertullian, Cyprian, the Acts

of the Apostles, Eusebius, and Chrysostom in the 4th century and

Basil, Gregory of Nyassa, Ambrose, Chrysostom and Jerome, all speak of

prayer for the dead and seem to imply belief in a purgatory, but

their view seems to have been affected by the pre-Christian doctrine

of Hades. Of some of the Greeks, notably Origen, teach that even the

perfect must go through fire in the next world. Augustine

writes (De VIII. Dulletii questionibus) that "it is not incredible

that imperfect souls will be saved by some purgatorial fire," to

which they will be subjected for varying lengths of time according

to their needs; but in other passages he seems to hold the contrary

opinions (De civitate, xx. 25, xxi. 13, 26; Enchiridion, 69). Gregory

the Great was the first to formulate the doctrine in express terms, "de

equibus sanitatem culpis esse judicale purgatorium ignis credendus est

diligenter praebet," and made the regulation a part of the

law of the Western Church, and was definitely affirmed at the councils

of Lyons (1274), Florence (1439) and Trent. Concerning the word

purgatory, Innocent IV. writes: "Forasmuch as (the Greeks) say

that this place of purification is not indicated by their doctors by

an appropriate and accurate word, we will, in accordance with the

tradition and authority of the holy fathers, that henceforth it be

called purgatorium, for in this temporary fire are cleansed not
deadly captives or Niches, which cannot be remitted by penance, but

those lesser venial sins which, if not removed in life, afflic men after death.

Many points about purgatory, on which the Church has no

definition, have been subjects of much speculation among

Catholics. Purgatory, for example, is usually thought of as

having some position in space, and as being distinct from heaven

and hell; but any theory as to its exact latitude and longitude,

such as underlies Dante's description, must be regarded as

imaginative. Most theologians since Thomas Aquinas and

Bonaventura have taught that the souls in purgatory are

tormented by material fire, but the Greeks have never accepted

this opinion. It must be inferred from the whole practice of

indulgences as at present authorized that the pains of purgatory

are measurable by years and days; but here also everything

is indefinite. The Council of Trent, while it commands all bishops

to teach "the sound doctrine of purgatory handed down by the

treasnable fathers and sacred councils," bids them exclude from

popular addresses all the "more difficult and subtle questions

relating to the subject which do not tend to edification."
PURI—PURIFICATION

of the pre-Nicene fathers on the subject. An authoritative statement of the present Eastern doctrine is to be found in the Longer Catechism of the Orthodox Church (Q. 375)—

"Such souls as have departed with faith but without having had time to bring forth fruits meet for repentance may be aided towards the attainment of a blessed resurrection by prayers offered in their behalf, especially such as are offered in union with the oblation of the Body and Blood of Christ, and by works of mercy done in faith for their memory."

The efficacy of prayers for the dead, and indirectly the doctrine of purgatory, were denied by early Gnostic sects, by Arians in the 4th century, and by the Waldenses, Cathari, Albigenses and Lollards in the middle ages. Protestants, with the exception of a small minority in the Anglican communion, unanimously reject the doctrine of purgatory, and affirm that "the souls of believers are at their death made perfect in holiness and do immediately pass into glory." Rejection of an intermediate state after death follows the Protestant interpretation of justification by faith as logically as the doctrine of purgatory results from the Catholic idea of justification by works.

An analogy to purgatory can be traced in most religions. Thus the fundamental ideas of a middle state after death and of a purificatory process are met with in Zoroaster, who takes souls through twelve stages before they are sufficiently purified to enter heaven; and the Stoics conceived of a middle place of enlightenment which they called eternitas.

The principal authoritative statements of the Catholic Church on the doctrine of purgatory were made at the Council of Florence (Decret. unianiz.), and at that of Trent (Sess. vi. can. 30; Sess. xxii., c. 2, can. 3; Sess. xxv.). See H. J. D. Denziger's Enchiridion; J. B. Fegfeuer (Mainz, 1879); and L. Rix, Nuz und Tod der Engel (Regensburg, 1856). A very elaborate treatise from the Catholic standpoint is that of Cardinal Bellarmino, De purgatorio. The subject is discussed, moreover, in all major works on dogmatic theology. There is a representative Catholic statement by Hensen in the Kirchenlexikon under the title "Fegfeuer," 2nd ed., vol. 4, col. 1284—1296; and a corresponding Protestant presentation by Rud. Hoffmann in Hauck's Realencyclopädie, 3rd ed. vol. v. pp. 788—792 (C. H. H.).

PURI, or JAGANNATH, a town and district of British India, in the Orissa division of Bengal. The town is on the sea-coast, and has a railway station. Pop. (1901), 49,334, including an exceptional number of pilgrims. As containing the world-famous shrine of Jagannath (see JUGGERNAUT), Puri is perhaps the most frequented of all Hindu places of pilgrimage. Sanitation is effected by the Puri Lodging-House Act, which provides for the appointment of a special health officer, and for the licensing of lodging-houses both in the town and along the pilgrims' route.

The District of Puri has an area of 2499 sq. m. The population in 1901 was 1,017,284, showing an increase of 7·6% in the decade. For the most part the country is flat, the only mountains being a low range, rising in the west, runs south-east in an irregular line towards the Chilka lake and forms a water-parting between the district and the valley of the Mahanadi. The middle and eastern divisions of the district, forming the south-western part of the Mahanadi delta, consist entirely of alluvial soil; there is a network of channels through which the most southerly branch of that river, the Koyakhal, finds its way into the sea. The other rivers are the Bhargavi, the Daya and the Nem, all of which flow into the Chilka lake and are navigable by large boats during the rainy season, when the waters come down in tremendous floods, bursting the banks and carrying everything before them. The Chilka lake is one of the largest in India; its length is 44 m., and its breadth in some parts 20 m. It is separated from the sea only by a narrow sand bar. The lake is salt at certain places, where the mean depth ranging from 3 to 5 ft. Puri district is rich in historical remains, from the primitive rock-hewn caves of Buddhism—the earliest relics of Indian architecture—to the medieval sun temple at Puri, the Makara and the shrine of Jagannath. The annual rainfall averages 58 in.

Puri first came under British administration in 1803. The only political events in its history since that date have been the rebellion of the maharaja of Khurda in 1804 and the rising of the paiks or peasant militia in 1817—18. In the Orissa famine of 1866 more than one-third of the population of Puri is said to have perished. The district suffered from drought in 1897. It is served by the East Coast railway, which was opened throughout from Calcutta to Madras in 1841, with a branch to Puri town.

See Puri District Gazetteer (Calcutta, 1908).

PURIFICATION, in the study of comparative religion, may be defined as the expulsion or elimination by ritual actions and ceremonies from an individual or a community, a place or a dwelling, of the contagion of a taboo (q.v.) or ritual pollution, which is often conceived of as due to the presence of or haunting by an unclean spirit, and having for its effect disease, pain and death. In the higher religions the idea of purification has slowly developed into that of ethical liberation from sin and guilt. This development involves a distinction between the outward act and the inner act or motive, which we do not find even in the relatively advanced codes of the ancient Jews or of the Athenians of the 5th century B.C., for in both of these the taboo or guilt of homicide was the same whether accidentally or wilfully committed. It is part of this development that contrition, remorse and repentance come to be recognized, together with merely ritual acts, such as baptism and sacramental meals, as a condition of regaining the lost purity or status. The ethical ideal of atonement and purity of heart is at last attained when, as in the Society of Friends, all ritual acts are abandoned as indifferent to moral progress. The cross of the primitive taboo still encumbers the conscience in churches which insist on outward ritual performances as an element in holiness or moral perfection and purity. The tendency of civilization is more and more to antiquate them as obstacles rather than aids to the formation of character.

In most primitive societies the chief sources of ritual pollution are birth, death, bloodshed, blood, especially menstrual blood. Numberless other things are or have been taboo among different peoples, such as trees, colours, foods and drinks, persons, places, seasons. Persons and things brought even involuntarily into contact or association with these are tabooed, and only recover their normal condition by some rite of purification or catharsis. Such rites take various forms, according to the place of the taboo or impurity contracted. Very generally the impurity is due to the haunting by an unclean spirit or ghost, who must be driven off by exorcists invoking the name of a more powerful and clean spirit, which usually equals, or is the thing or spirit in place of the unclean. On this side rites of purification may become rites of consecration. In lower civilizations disease and madness are held to be caused by evil spirits which are similarly expelled; and on this side purificatory rites develop into the medical art. It must be borne in mind that a drug was originally not a substance succeeding by dint of its chemical properties and physical reactions on our bodies, but a talisman or charm taken internally and succeeding by reason of its magical properties.

Among the methods of purification used widely among different races and in various religions, the following may be enumerated, though the list might be indefinitely extended.

1. Peculiar sacrificial ceremonies occurring annually, intended to renew the life of the god in the worshippers. "Without shedding of blood there is no remission of sins" (Heb. ix. 22).

2. Vicarious sacrifice, whereby the guilt of an individual or of a clan is transferred to an animal, like the Jewish scapegoat, which is forthwith destroyed or sent over the frontier.

3. Washing or sprinkling with water, as a rule previously blessed or exorcised; or with the water of separation (i.e. water mixed with ashes of a red heifer).

4. Washing with water, as a rule previously blessed or exorcised; or with the water of separation (i.e. water mixed with ashes of a red heifer).

5. Anointing with holy oil.

6. Smearing with the blood, e.g. of the passover lamb or of a pig; or purificatory baptism with the blood of an ox in the Taurobolium (see MITHRAS).

7. Fumigation with smoke of incense used at sacrifices, the incense itself being the gum of a holy tree and gathered with magical precautions.

8. Rubbing with sulphur or other lye. Use of helioloe, hyssop, &c.

9. Burning with fire objects in which the impurity has been confined.

10. Sprinkling with water in which the cross has been washed (used for flocks and fields in Armenia).

11. Evil spirits are expelled by invocation of the name of a being more powerful than they, and by the introduction of a clean spirit.

12. By fasting.

13. In the old Parsee religion the drugs or demons which infect a corpse may be driven off by the look of certain kinds of dogs.

14. An impure contagion may be removable together with hair, nails or bits of clothing. Hence the use of the tonsure and the custom of shaving the head in vows.
Purim, a Jewish festival held on the 14th and 15th of Adar, the last month of the Jewish calendar. According to Jewish tradition it is held in celebration of the deliverance of the Jews from the massacre plotted against them by their enemy Haman in the time of Artaxerxes, who fixed upon the former date by casting "lots" (=Hebrew loan-word Purim). It is preceded by a fast on the 13th day of Adar, known as the Fast of Esther, based upon Esther iv. 16.

Purim is the carnival of the Jewish year. 'Friends exchange gifts, and thus occasion is taken to relieve the necessities of the poor in the most considerate manner. The drains of gifts are open.' The children masquerade, and their parents are enjoined to drink wine until they cannot distinguish between blessing Mordecai and cursing Haman. The Megillah or Roll of Esther is read both at home and in the synagogue, and whenever, during the reading, the name of Haman is mentioned, it is accompanied with trampling of feet. In former times Haman was burnt in effigy, holding on to a ring and swinging from one side of the fire to the other (see L. Ginzberg, Geonica, 1909, pp. 1, 419; Davidson, Parody, pp. 21-22). This custom, which is still observed among the Jews of Caucasia (Tochni, Sepher ha-Masaq, pp. 101-102), is very ancient, as it is mentioned in the Talmud (Sanhedrin 64a).

From the 17th century onward Purim plays were performed mostly by the children, who improvised a dramatic version of the story of Esther. This grew to be the characteristic folk-drama of the ghetto, and has not died out in eastern Europe to the present day.

Much ingenuity has been spent upon the name and origin of the feast of Purim. Some, as a rule, may dismiss at once the suggestions of J. Fuerst (Kanon des Alten Testaments) that it is derived from the Persian bahar, "spring," and of Hézig (Geschichte Israels), who derives it from the modern Arab Purr, "the New Year." These conjectures were made in the pre-scientific era of philology. Secondly it is said to be in favour of the suggestion made by Von Hammer; but better known in connexion with the name of Lagarde, who connects the name Purim with the old Zoroastrian festival of the dead, customarily celebrated on the 15th of Adar.

Lagarde connects this form with the LXX. variant of the Hebrew (purbal); but there is absolutely nothing about Purim which suggests any relation with a festival of the dead. Graetz's suggestion (Monats. Jud. xxxv. 10 seq.) that it is derived from the Hebrew purlar, "the power of the king," is by no means certain, while that of a spring festival of joyousness with the autumn wine harvest (Zimmern, ZATW xi. 157 seq.) connects Purim with the purlar or assembly of the gods, which forms part of the Babylonian New Year festival Zagmukru, but the inserted gutter is against the identification.

The most plausible etymology connects the name with the Assyrian purū, either in the sense of "turn " of office at the beginning of the New Year" (as of "pebble") used for votes or lots, as with the Greek ἔκβολος. It is a curious coincidence, to say the least, that Diodorus found among the ruins of the Memnonium at Susa (the ancient Shushan, given as the scene of the events narrated in the Book of Esther) the quadrangle shown in the usual illustrations of the scene, complete with the figures on the walls. This etymological connexion, suggested by Jensen (Kosmologie, 84), brings the festival of Purim into close relation with the Babylonian New Year festival known as Zagnmukru, in which one of the most prominent ceremonies was the erection of an assembly of the gods under the presidency of Marduk (Merodach) for the purpose of determining the fates of the New Year. Meissner (ZDMG, i. 296 seq.) and others have suggested that the drunkenness and masquerading current at the period of Purim are directly derived from the general period of licence allowed at the Sacraea festival of the Babylonian New Year. Even the fact that this latter was celebrated on the first of Nisan, or a fortnight after the Jewish date for Purim, is confirmed by the Book of Esther itself, which states that "In the first month, which is the month Nisan, they cast Pur, that is, the lot, before Haman" (Esther iii. 7-ix. 26). The change of date may have been made in order not to conflict with the Passover of Nisan, and it is suggested by Renan, that two names of Purim were suggested between the names of Mordecai and Esther and those of the Assyrian deities Marduk and Ishtar would be a further strong confirmation of the proposed etymology and derivation of the feast (see ESTHER).

Going still further, J. G. Frazer connects Purim with the whole story of Haman and the Purification of Haman's name, and suggests, along with Purim, a symbolic idea, of the god of vegetation was put to death and a new human representative of him elected and allowed to have royal and divine rights, so as to promote the coming harvest (Golden Bough, 2nd ed., vol. iii. p. 154 seq.).

By the time of Josephus we learn how the feast was celebrated by the book of Esther on the 13th of Adar, the day before Purim, while the rejoicing on Purim itself, and the licence accompanying it, recall the union of the god and goddess of vegetation, of which he sees traces in the customs of Mordecai and Esther. There may possibly be "survivals" of the influence of some such celebrations both on the Book of Esther and on the ceremonies of Purim, but there is absolutely no evidence that the Jews took over the interpretation of the festival with their celebration. Nor is there any record of royal privileges attaching to any person at the period of Purim such as occurs in the festivals with which it is supposed to be connected by Graetz. His further suggestion, therefore, that the ironical crowning of Esther and the reverse execution of Haman together with the selection of Barabbas, had anything to do with the feast of Purim, must be rejected. The connexion of the Passion with the Passover rather than Purim would alone be sufficient to nullify the suggestion. However, it is practically certain, both from the etymology of the word Purim and from the resemblance of the festivals, that the feast, as represented in the Book of Esther, was borrowed from the Persians, who themselves appeared to have adapted it from the Babylonians. This is confirmed by the fact that the Book of Esther contains several Persian words and shows throughout a familiarity with Persian conditions. This renders it impossible to accept Hapet's suggestion that Purim is connected with the celebration of Niconar's Day, to celebrate the triumph of Jewish arms at the battle of Niconar (B.C. 524), which was celebrated on the 13th of Adar, since this is the date of the Fast of Esther, and, besides, the Second Book of Maccabees, which refers to Niconar's Day, speaks of it as the day before Mordecai's Day (2 Macc. xvi. 36).

If, therefore, this festival of Esther is connected with a date made about 175 B.C. (Swee, Introduction of the Old Testament in Greek, p. 25), this suggestion of the connexion of Purim with the Maccabean period made by Hapet and, before him, by Willrich, falls to the ground.

At the same time it is difficult to understand why Jews in Palestine and Egypt should have accepted a purely Persian or Babylonian festival long after they had ceased to be connected with the Persian Empire. One can understand its adoption during, or soon after, the Persian period; but, since it was then in existence, it may easily have become as popular among them as Christmas tends to become among modern Jews. When the exiles returned from Babylon they probably brought back with them the practice of keeping the festival.

The date at which the feast of Purim was first adopted by the Jews from their Persian neighbours would be definitely determined if we knew the date of the Book of Esther. The festival is first mentioned in 2 Macc. xv. 36, and from that time onwards has formed one of the most popular festivals of the Jewish calendar. It became customary to burn an effigy of Haman at the conclusion of the feast, and this was regarded as in some ways a substitute for the burning of Haman himself by the Book of Esther (Theodosian code, XVI. viii. 18). This prohibition may have been due to the fact mentioned by Socrates (Hist. eccles. vii.) that, in 416 A.D., the Jews of Immer, a town in Syria, ill-treated a Christian child during some Purim pranks and caused his death. It has even been suggested that this gave rise to the myth of the blood accusation in which Jews are alleged to have sacrificed a Christian child at Passover; but this is unlikely, since it has never been suggested that this crime was connected in connexion with Purim. But Jewish sources of the 10th century state that the custom of burning an effigy of Haman was still kept up at that time (L. Ginzberg, Geonica, ii.), and this is confirmed by Albruni (Chronology, tr. Sachau, 273) and Makrizi, and indeed the custom was carried on down to the present century by Jewish children, who treated Haman as a sort of Guy Fawkes. Frazer suggests (loc. cit. 172) that this is a survival
of the burning of the man-god, like Hercules or Sandan, who again represented the old spirit of vegetation which was dying away in spring to revive with the new vegetation. The earliest mention, however, of this burning of Haman in effigy cannot be traced back earlier than the Talmud in the 5th century.

In connexion with Purim many quaint customs were introduced by the Jews of later times. All means are adapted to increase the hilarity of the two days, which are filled with feasting, dancing, singing and making merry generally. In Germany it was even customary for men to dress up as women, and women as men, against the command of Deut. xxii. 5. In Frankfort the women were allowed to open their lattice windows in the synagogue in honour of the deliverance brought about by Esther. Execution of Haman, as the typical persecutor of the Jews, took various forms. In Germany wooden mallets were used in the synagogue to beat the benches when Haman's name was read out from the scroll of Esther, and during the festivities these mallets were sometimes used on the heads of the bystanders. Cakes were made of a certain shape to be eaten by the children, which were called, in Germany, Hamantaschen (Haman-pockets) and Hamanhoren (Haman-ears), and in Italy, Orecchie d'Aman. In Italy a puppet representing Haman was set up on high amidst shouts of vengeance and blowing of trumpets. In Caucasus the women made a wooden block to represent Haman, which, on being discovered by the men on their return to the synagogue, was thrown into the fire. Besides gifts to friends, parents made Purim gifts to their children, especially in the form of Purim cakes. To preside over these festivities it was customary to have a master of the ceremonies, who was called king in Provence, somewhat after the manner of the Feast of Fools. In later days the same function was performed by the Purim Rabbi, who often indulged in parodies of the ritual.

With Purim is connected the only trace of a true folk-drama among Jews. The first Spanish drama written by Jews was entitled “Esther,” by Solomon Usque and Lazaro Gratiano, published in 1567; and there is another entitled “Comedia famosa de Aman y Mordechay,” produced anonymously in Leiden in 1690. Among the German Jews Purimspiele were frequent and can be traced back to the 16th century, where there is reference to their being regularly performed at Tannhausen. The earliest one of these printed was entitled “Ahaswerosch-Spiel,” appeared at Frankfort in 1708, and was reprinted by Schudt in Juedische Merck-Wuerdigkeiten, ii. 314 seq. These were followed by a large number of similar reproductions, none of any great merit, but often showing ingenuity in parading more serious portions of the Jewish ritual (Davidson, Parody, p. 127, 59, 190 seq).

Besides the general festival of Purim, various communities of Jews have instituted special local Purims to commemorate occasions when they have been saved from disaster. Thus the Jews of Cairo celebrated Purim on the 28th of Adar in memory of their being miraculously saved from the persecution of Ahmed Pasha in 1524. The Jews of Frankfort celebrate their special Purim on the 20th of Adar because of their deliverance from persecution by Fetmollah in 1616. The Jews of Algiers similarly celebrated the repulse of the emperor Charles V. in 1541, by which they escaped coming once more into the yoke of the Spaniards. Similar occasions for rejoicing were introduced by individuals into their families to celebrate their escape from danger. Thus Abraham Danzig celebrated in this manner his escape from the results of an explosion of a powder magazine at Wilna in 1804. Rabbi Enoch Alshagul of Prague recorded how a young child on the 22nd of Tishri 1708 (11th Adar) was found under a large boulder, with the name ‘megillah,’ which was to be read by his family on that date with rejoicing similar to the general Purim. David Brandes of Jung-Bunzlau in Bohemia was saved from an accusation of poisoning on the 10th of Adar 1731, and instituted a similar family Purim celebration in consequence.

Erb, Die Purimsgeschichte (Berlin, 1900); Abrahams, Jewish Life in the Middle Ages: Lagarde, Purim, ein Beitrag zur Geschichte der Religion (Göttingen, 1886); Steinschneider, Purim und Parodie (Berlin, 1902); P. Haupt, Purim (Leipzig, 1906); Davidson, Parody in Jewish Letters, pp. 21, 30, 135-39 (New York, 1908).

(P. J. A.)

**PURIN**

**C$_4$H$_7$N$_3$O$_4$,** the name given by Emil Fischer to the parent substance of a large group of compounds, the more important of which are sarcine, xanthine, uracil, adenine, paraxanthine, guanine, theophylline, theobromine and caffeine. Its formula is shown in the inset, the positions taken by substituted atoms or groups being numbered as shown. E. Fischer (Ber., 31, p. 256a) obtained it in 1898 by reducing 2-6-dilido purin, obtained from 2-6-trichlor purin (see below sub Uric acid), hydriodic acid and phosphonium iodide at $0^\circ$, with zinc dust and water, the zinc double salt so obtained being decomposed by sulphurised hydrogen, the precipitated zinc sulphide filtered off and the solution concentrated. It has also been synthesized by O. Isay (Ber., 1906, 39, p. 25c) from 5-nitro-uracil. This substance with phosphorus oxychloride gives 2-4-dichlor-5-nitro pyrimidine, which with ammonia gives 4-amino-2-chlor-5-nitro pyrimidine; by reducing this compound with hydriodic acid and phosphonium iodide, 4-5-diamino-pyrimidine is obtained, which with formic acid furnishes purin; thus:

\[
\begin{align*}
\text{NH-C} & \text{N} \text{CH} \text{N} \text{CH} \text{N} \text{CH} \\
\text{CO} & \text{CO} \text{O} \text{NO}_2 \rightarrow \text{CIC} \text{C} \text{NO}_2 \rightarrow \text{CIC} \text{C} \text{NO}_2 \rightarrow \text{HCC} \text{NH} \rightarrow \text{HCC} \text{NH} \\
\text{NH} & \text{CO} \rightarrow \text{N} \text{CCl} \\
\text{N} & \text{NH} \rightarrow \text{N} \text{NH} \rightarrow \text{N} \text{NH} \rightarrow \text{N} \text{NH} \\
\end{align*}
\]

Purin crystallizes in microscopic needles, which melt at 216°C. It possesses the properties of both an acid and a base. It is characterized by its ready solubility in water and by its stability towards oxidizing agents.

**Oxyurins.** Sarcine or hypoxantine, C$_3$H$_7$N$_3$O, is 6-oxypurin. It is found in many animal liquids and organs and in the seeds of plants. It was first described by J. Scherer in milk (Ann., 1850, 73, p. 328) and by A. Strecker in muscle. It crystallizes in needles which decompose at 150°C. It was synthesized by E. Fischer (Ber., 1897, 30, p. 2228) by heating 2-6-8-trichlor purin with aqueous caustic potash, and reducing the dichlorhypoxantine so obtained by hydriodic acid. Its aqueous solution shows acid properties, decomposing carbonates. It also forms a hydrochloride, C$_3$H$_7$N$_3$O$\cdot$HCl$\cdot$H$_2$O. When oxidized by hydrochloric acid and potassium chloride it yields alloxan and urea, whilst with potassium permanganate it gives oxalic acid.

3-Methylhypoxantine was synthesized by W. Traube and F. Winter (Arch. Pharm., 1906, 244, p. 11), whilst 8-oxypurin was obtained by E. Fischer and L. Ach in 1897 (Ber., 30, p. 2213), and by O. Isay (Z. Chem., 1906, 39, p. 251).

**Xanthine, C$_5$H$_7$N$_3$, or 24-dioxypurin, was discovered in 1817 by Marcat in a urinary calculus; it also occurs in various animal organs (the liver, pancreas and muscular tissue), in urine, and in the mushroom juice. It may be prepared by boiling nuclei with water, followed by the decomposition of guanine with nitric acid (A. Strecker, Ann., 1858, p. 141); and by heating the formyl derivative of 4-5-diamino-2-6-dioxypurin (Traube, Ber., 1900, 33, p. 3935). This pyrimidine is prepared from cyanacetyl urea, which on treatment with a concentrated solution of sodium hydroxide is converted into 4-5-diamino-2-6-dioxypurin. The isomorrotio derivative of this compound is then reduced by ammonium sulphide to 4-5-diamino-2-6-dioxypurin, the formyl derivative of which, on heating passes into xanthine.

\]

**Potassium cyanurate** decomposes when heated, giving ammonia, carbon dioxide and hydrocyanic acid. It possesses both acid and basic properties. When heated with concentrated hydrochloric acid to 220°C, it decomposes into carbon dioxide, ammonia, glycine and formic acid. Potassium cyanurate, hydrocyanic acid oxidize it to alloxan and urea. Methylation of its lead salt gives theobromine.

**6-8-dioxypurin was prepared by E. Fischer and L. Ach (loc. cit.).**

1-Methylxanthine was found in urine by M. Krüger and G. Salomen (Zett. physiol. Chem., 1897, 24, p. 364); 3-methylxanthine was obtained by E. Fischer and F. Ach (Ber., 1898, 30, p. 1980) from 3-methyl uric

2

N4,

or

l-3-dimethyl-2-6-dioxypurin,

was isolated by A, Kossel from tea-leaves (Ber., 1888, 21, p. 2164).
It was synthesized by E. Fischer and L. Ach {Ber.,
1895, 28, p. 3135)
from i-3-dimethyl uric acid, which on treatment with phosphorus
pentachloride yields chlortheophylline, from which theophylline
is obtained by reduction with hydriodic acid.
W. Traube (Ber., 1900,
33.. P- 3°35) formed the nitroso derivative of iminodimethyl barbituric acid (obtained by the action of phosphorus oxychloride
on cyanacetic acid and dimethyl urea), and reduced it by ammo-

nium sulphide to l-3-dimethyl-4-5-diamino-2-6-dioxypyrimidine, the

formyl derivative of which, when heated to 250 C, loses the elements
water and yields theophylline (cf. Xanthine). It behaves as a
weak base. When oxidized by potassium chlorate and hydrochloric acid it yields dimethylalloxan. Its silver salt on methylation
yields caffeine.
of

The

isomeric

Paraxanthine, or l7-dimethyl-2-6-dioxypurin,
occurs in urine. It has been obtained from theobromine (E. Fischer,
Ber., 1897, 30, p. 2400); from 17-dimethyl uric acid (E. Fischer
and H. Clemm, Ber., 1898, 31, p. 2622); and from 8-chlorcaffeine

(E

Fischer, Ber.,

1906, 39, p. 423).

On

methylation

it

yields

caffeine.

A third isomer Theobromine, or 37-dimethyl-2-6-dioxypurin, is
found in the cocoa-bean (from Theobroma cacao) and in the kola-nut.
It is obtained by methylating xanthine, or from 3-7-dimethyl
uric
acid (E. Fischer, Ber., 1897, 30, p. 1839). This acid, by the action
of phosphorus oxychloride and pentachloride, is converted
into
37-dimethyl-6-chlor-2-8-dioxypurin, which with ammonia gives
the corresponding amino compound.
This substance with phosphorus oxychloride yields 37-dimethyl-6-amino-2-oxy-8-chlorpurin,
which on reduction with hydriodic acid leads to 37-dimethyl-6amino-2-oxypurin, from which theobromine is obtained by the
action of nitrous acid. It is also obtained by W. Traube's method
(Ber., 1900, 33, p. 3047) from cyanacetyl methyl urea, which
gives
3-methyl-4-5-diamino-2-6-dioxypyrimidine, whose formyl derivative yields 3-methylxanthine, from which theobromine is
obtained
by methylation.
It crystallizes in anhydrous needles which sublime
at 290-295° C.
It behaves as a weak base.
Potassium chlorate
and hydrochloric acid oxidize it to methyl alloxan and methyl urea,
chromic acid mixture oxidizes it to carbon dioxide, methylamine and
methylparabanic acid. When boiled with baryta it yields carbon
dioxide, ammonia, methylamine, formic acid and sarcosine. Methylation of its silver salt yields caffeine.
Caffeine, C 6
is l-37-trimethyl-2-6-dioxypurin.

Apocaffeine when boiled with water loses carbon dioxide and
yields
caffuncacid, C 6 H 9 N 3 04, which on hydrolysis with basic lead acetate
is
converted into mesoxalic acid, methylamine and monomethyl
urea
Reduction of caff uric acid yields hydrocaffuric acid, C H N
8
9
2
3
which readily hydrolyses to methyl hydantoin.
Consequently
hydrocaffuric and caffuric acids, apocaffeine and caffeine
must
contain the grouping (I.). Hypocaffeine on hydrolysis loses
carbon
dioxide and gives caffolin, C 6 9 3 2 which on oxidation
with
alkaline potassium femcyanide yields monomethyl urea
and methyl
oxamic acid, whilst if oxidized by alkaline potassium permanganate
it yields dimethyl oxamide.
Hence caffolin contains the grouping
(II.), and in consequence of its close relationship to
hydrocaffuric
acid is to be written as (III.). It follows that the caffeine
molecule
must be written as (IV.), a result confirmed by the later synthesis
of caffeine itself from dimethyl alloxan (see above).

Caffolin/

Uric acid, CjHiN^,, or 2-6-8-trioxypurin, was
discovered in
1776 in urinary calculi by Scheele. It is found in the juice of
the
muscles, in blood, in urine, in the excrement of serpents
and birds
and in guano. The determination of the constitution and
of the
relation of uric acid to the other members of the
group has been a
process of gradual growth.
G. Brugnatelli ((Zornale di fisica
chemtca, &c, di Brugnatelli, 1818, n, pp. 38,
117) obtained alloxan
and W. Prout (Phil. Trans., 1818, p. 420) obtained ammonium
purpurate from uric acid, but the first elaborate investigation
on
the acid was by J. v. Liebig and F. Wohler (Ann.,
1838, 26 p 241)

who obtained from it allantoin, alloxantin, dialuric acid, parabanic
oxalunc acid, mesoxalic acid, &c. Further examination
of
the group was undertaken by A. Schlieper (Ann.,
1845, 5s p 2 <;656, p. 1), who obtained hydurilic acid and dilituric acid, and 'by A
v'
Baeyer (Ann 1863, 127, pp. 1, 199; 1864, 130, p. 129;
131, p 291)'
who showed that uric acid and many of its derivatives may be looked
on as derivatives of barbituric acid. In 1875 L. Medicus (Ann
i875. 1.75. P- 230) proposed the formula (I.) for the
acid, whilst
R. Fittig
1877 (Traite de chim. org., p. 324 [1878]) suggested the
formula (II.) subsequent investigations of R. Behrend and

Dimethyl-diamino-dioxypyrimidine (see Theophyllin above) yields
a formyl derivative which on treatment with
sodium ethylate
furnishes a sodium salt.
This salt heated for some hours with

The constitution of caffeine was settled by E. Fischer (Ann.,
I882, 215, p. 253). Earlier investigations had
shown that oxidation
with nitric acid gave dimethylparabanic acid or
cholesterophane
J. btenhouse, Ann., 1843, 45, p. 366) that chlorine water oxidized

4-5-diamino-2-6-dioxypynmidine (W. Traube, Ber., 1900,
33, p.
3042)- The three latter methods may be outlined as follows. Dimethylalloxan (I.) condenses with methylamine in the presence of
sulphurous acid to form an addition product (II.), which on hydrolysis
yields i-37-tnmethyl uramil; this substance gives with
potassium
cyanate, I -37-tnmethyl pseudo-uric acid (III.), which on dehydration
yields I -37-tnmethyl uric acid (hydroxycaffeine)
this substance
with phosphorus pentachloride gives chlorcaffeine, which yields
caffeine (IV.) on reduction:

lat lon

'

water
gave monomethyl urea and dimethyl alloxan, pointing to the presence of three methyl groups in the molecule. Further, on bromination, a brom-derivative is obtained which on treatment
with
alcoholic potash yields ethoxy-caffeine, which readily hydrolyses
to
hydroxy-caffeine. This substance behaves as an unsaturated
compound and combines with a molecule of bromine to form a derivative
which on treatment with alcoholic potash yields diethoxy-hydroxycaffeine.
Diethoxy-hydroxycaffeine on hydrolysis with concentrated hydrochloric acid yields apocaffeine, C 7 H N O
and hypo7
3
s

0C
For

general properties and method of extraction see Caffeine.
It may be synthesized by methylating chlortheophylline
and reducing the resulting product (E. Fischer and L. Ach, Ber.,
1895, 28,
P-.3 X 35); by the action of phosphorus oxychloride on tetramethyl
uric acid, the resulting chlorcaffeine being reduced (Ber.,
1897, 30
p. 3010); from dimethylalloxan (Ber., 1897, 30, p. 564)- from
3-methyl uric acid (Ber., 1898, 31, p. 1980), and from l-3-dimethylits

to amalic acid or tetramethyl alloxantin (Fr. Rochleder,
Ann
1849, 71 p. 1), and that hydrolysis with baryta gave caffeidine
(A. Strecker, Ann., 1862, 123, p. 360), which could be further
hydroe
sarcoslne methylamine, formic acid and carbon dioxide
/?? c 1° ,
Fischer confirmed
these results and showed further that oxidation with chlorine
it

'

baczewski obtained the acid by heating urea with
ammo-acetic
acid (glycine) to 200-230 C, and by fusing urea
with trichlorlactamide. In Behrend's method acetoacetic ester and
urea (I.) are
condensed and the resulting /3-uramidocrotonic ester (II.) on hydrolysis gives methyl uracil (III.), which
on treatment with concentrated
nitric acid yields nitro-uracil
carboxylic acid (IV.). This acid
when boiled with water loses carbon dioxide, forming nitro-uracil
•/"• reduction gives amido-uracil (VI.) and oxy-uracH
uin
(VII). Oxidation of oxy-uracil with bromine water leads
to dioxy-

A

uraal (VIII.), which when heated with urea and concentrated
sulphuric acid yields uric acid (IX.)

:


E. Fischer dehydrated pseudo-uric acid (from potassium cyanate and uramil) by heating it with anhydrous oxalic acid to 185°C, or with a large excess of 20% hydrochloric acid (Ber., 1887, 30, p. 560), and so obtained uric acid. This method is quite general. W. Traube's synthesis of 7-dimethyl-8-oxypurin (I) (see Xanthine, above) with chloroboric ester, the resulting urethane (II) when heated to 180-190°C loses a molecule of alcohol, giving uric acid (III).

\[

\]

(Uric acid is a white, microcrystalline powder. It is odourless and tasteless, and is insoluble in most reagents. Its solubility in water is increased by the presence of various inorganic salts, such as sodium phosphate, sodium acetate, borax, and particularly by lithium carbonate, which causes a precipitated soluble phos- 

It may be recognized by means of the "murexide" reaction, which consists in evaporating the acid to dryness with nitric acid, when a yellowish residue is obtained which becomes purplish on the addition of sodium nitrite. On the estimation of uric acid see F. W. Tunnicliffe (Chem. Centralb., 1897, 11, p. 987; E. H. Bartley, ibid., p. 644 and F. G. Hopkins, Chem. News, 1892, 66, p. 106).

M. Bechamp showed in 1866 that 1-Methyl uric acid was prepared by E. Fischer and H. Clemen (Ber., 1897, 30, p. 3991) from monomethyl alloxan and ammonium sulphite, which condense together to form 1-methyluric acid. This, with potassium cyanate, gives 1-methyl-4-uric acid, which on dehydration gives 1-methyl uric acid. 3- or a-Methyl uric acid was prepared by Hill (Ber., 1876, 9, p. 370) by heating acid lead urate with methyl iodide. It is best obtained by heating 3-methyl chlorxanthine with hydrochloric acid to 125°C (E. Fischer, Ber., 1896, 31, p. 1984). 

\[
\begin{align*}
CH\text{N}-CO-C-NH_2-CH_2-N\text{H}_2-CH_2-CO_2\text{H} & & \quad H\text{N}-CO-C-NH_2-CH_2-N\text{H}_2-CH_2-CH_2-CO_2\text{H} & & \quad H\text{N}-CO-C-NH_2-CH_2-N\text{H}_2-CH_2-CH_2-CH_2-CO_2\text{H} \\
(\text{I}) & & (\text{II}) & & (\text{III})
\end{align*}
\]

It has also been obtained by B. Ach, Ber., 1901, 34, p. 1177 by the electrolytic reduction of guanine to deoxyguanine, the acetate of which is warmed with bromine and subsequently oxidized. 

9-Methyl adenine was first obtained by I. Krieger (Zeit. f. Physiol. Chem., 1902, 35, p. 41) by heating guanine with hydrochloric acid and ammonium sulphite. W. Traube (Ber., 1902, 33, p. 3217) condensed cyanacetic ester with guanine and the resulting compound (I) with caustic soda gives 2-diamino-4-pyrimidylestyrmine (II). This compound when boiled with ammonium sulphide gives 2,4,5-triamino-6-pyrimidylestyrmine (III), from which guanine (IV) is obtained by treating with formic acid.

\[
\begin{align*}
H\text{N}-CO & \quad N\text{C}-\text{OH} & \quad N\text{C}-\text{OH} & \quad N\text{C}-\text{OH} & \quad H\text{N}-CO \\
(\text{I}) & & (\text{II}) & & (\text{III}) & & (\text{IV})
\end{align*}
\]

It may also be obtained as follows [E. Merck, German Patents 599655 (1912)] (Biologische Blatter, 1896, 25, p. 238; 1898, 11, p. 324) by heating a cyanacetic ester with 2-diamino-4-pyrimidylestyrmine (II). This yields an isonitroso-derivative which on reduction gives 2-cyanamino-4,5-diamino-6-pyrimidylestyrmine (III). This compound when boiled with a 90% solution of formic acid gives guanine formate.

\[
\begin{align*}
\text{NH} & \quad N\text{C}-\text{NH}_2 & \quad N\text{C}-\text{NH}_2 & \quad N\text{C}-\text{NH}_2 & \quad \text{NH}_2 \\
(\text{I}) & & (\text{II}) & & (\text{III})
\end{align*}
\]

It is an amorphous powder, insoluble in water, alcohol and ether, and has both acid and basic properties. Nitric acid converts it into nitroguanine. When boiled with potassium cyanate and ammonium carbonate, it yields guanine, parabanic acid and carbon dioxide.

6-Amino-2-oxypurin, an isomer of guanine, is prepared by heating dichloradenine or 6-amino-2-6-8-trichlorpurin, obtained from 2-6-8-trichloradenine and ammonium (Fischer, Ber., 1897, 30, p. 2239) with sodium ethylate to 130°C and reducing the resulting 6-amino-2-ethoxy-8-chlorpurin with hydroxide (E. Fischer, Ber., 1897, 30, p. 2245).

6-Amino-8-oxypurin, another isomer of guanine, is prepared by heating 8-oxo-2-6-dichlorpurin with alcoholic ammonium hydroxide to 120°C. It is also obtained by heating uric acid and the methyl uric acid. It has a neutral reaction.
PURITANISM—PURPURA

7-Methyl guanine is obtained from 7-methyl-6-0x2-chlorpurin (see above) by the action of aqueous ammonia at 150° C. It also results instead of the expected 7-methyl-2-oxo-aminopurin, when 7-methyl-6-amino-2-chlorpurin is treated with dilute alkalis (E. Fischer, Ber., 1890, 2, 942). It is formed by splitting in the 1-6-position, followed by eliminating of halogen acid.

Thiopurins.—W. Traube (Ann., 1894, 331, pp. 66 seq.) has obtained many compounds of the purin group by using thiozura, which is condensed with cyanacetic ester, &c., to form thiopyrimidines. These in turn yield thiopurins, which on oxidation with dilute nitric acid are converted into purin compounds, thus:

\[ \text{H}_2\text{N-COR} \quad \text{HN-CO} \quad \text{HCN} \quad \text{H-C-NH} \]

Various thiopurines have been obtained by E. Fischer (Ber., 1898, 31, 431), by acting with potassium sulphide on chlorinated purin compounds.

2-8-Thriothiopurin is obtained from the corresponding trichlorpurin and potassium sulphide. It forms a yellow mass which carbonizes on heating. It is almost insoluble in water and alcohol; but readily dissolves in dilute solutions of the caustic alkalis and acids. It is also decomposed by pyridine.

Much work has been done by J. Tafel (Ber., 1900, seq.) on the electrolytic reduction of the members of the purin group. The substance to be reduced is dissolved in a 50-75% solution of sulphuric acid, in a porous cell containing a lead cathode, the whole being then placed in a 20-60% solution of sulphuric acid in the anode cell. It is found that xanthine and its homologues take up four atoms of hydrogen per molecule and give rise to the so-called 'purinoids,' which are stronger bases than the original substances. Uric acid takes up six hydrogen atoms per molecule and gives purone, \( \text{C}_4\text{H}_4\text{N}_2\text{O}_2 \), and it is apparently the oxygen atom attached to the carbon atom number 6 which is replaced by the hydrogen. When purone is heated with baryta, two molecules of carbon dioxide are liberated for one of purone. Consequently purone must contain two urea residues, which necessitates the presence of the \( \text{CO}_2 \) groups in positions 2 and 8. (F. G. P. *)

PURITANISM (Lat. puritas, purity), the name given—or originally perhaps in a hostile sense on the analogy of Catharism (see Cathars)—to the movement for greater strictness of life and simplicity in worship which grew up in the Church of England in the 16th century among those who thought that there had not been a sufficient divergence from the Roman Church, and which ultimately led to the rise of a number of separatist denominations. It should be observed that the use of the term “Puritan” to 1564. The terms “Precisian,” “Puritan,” “Presbyterian,” were all used by Archbishop Parker in his letters about this time as nicknames for the same party, and ten years later the name was in common use.

See England, Church of; Congregationalism; Presbyterianism, &c.; also D. Neal, History of the Puritans (ed. Toulmin, 5 vols., 1822); E. Dowden, Puritan and Anglican (1901); J. Heron, A Short History of Puritanism (1908).

PURLIEU, a word used of the outlying parts of a place or district, sometimes in a derogatory sense. It was a term of the old English forest law (q.v.), and meant, as defined by Manwood (Treatise of the Forest Laws), “a certain territory of ground adjoining unto the forest,...which...was once forest-land and afterwards deforested by the perambulations made for the severing of the new forests from the old.” The owner of freeholds in the purlieu to the yearly value of forty shillings was known as a “purlieu-man” or “purlie-man.” There seems no doubt that “purlieu” or “purliey” represents the Anglo-French purulé, purule, O. Fr. puruler, puruler, to go through, Lat. perambulare), a legal term meaning properly a perambulation to determine the boundaries of a manor, parish, &c.

PURLIN, a term in architecture for the longitudinal timbers of a roof, which are carried by the principal rafters and the end walls and support the common rafters.

PURNA or Purniah, a town and district of British India, in the Bhagalpur division of Bengal. The town is on the left bank of the little river Sura, with a railway station. Pop. (1901), 14,097. It has a bad reputation for fever.

The District of Purnia has an area of 4094 sq. m. and a population (1901) of 1,874,794, showing a decrease of 3-6% in the decade. The district extends from the Ganges northwards to the frontier of Nepal. It is a level, depressed tract of country, consisting for the most part of a rich, loamy soil of alluvial formation. It is traversed by several rivers flowing from the Himalayas, which afford great advantages of irrigation and water-carriage; in the west the soil is thickly covered with sand deposited by changes in the course of the Kusi. Among other rivers are the Mahananda and the Panar. Under Mahomedan rule Purnea was an outlying province, yielding little revenue and often in a state of anarchy. Its local government raised a rebellion against Suraj-ud-daula in 1759, after the capture of Calcutta. The principal crops are rice, pulses and oilseeds. The cultivation of indigo is declining, but that of jute is extending. The district is traversed by branches of the Eastern Bengal railway, which join the Bengal and North-Western railway at Katihar.

PURPLE, a colour-name, now given to a shade varying between crimson and violet. Formerly it was used, as the origin of the name shows, of the deep crimson colour called in Latin purpura, purpureus and in Greek πορφύρα, πορφυρός (from πόρφυρος, to grow dark, especially used of the sea). This was properly the name of the shellfish (Purpura, Murex) which yielded the famous Tyrian dye, the particular mark of the dress of emperors, kings, chief magistrates and other dignitaries, whence “the purple” still signifies the rank of emperors or kings.

The title of porphyrogenitus (Gr. πορφυρογέντος) was borne particularly by Constantine VII., Byzantine emperor, but was also used generally of those born of the Byzantine imperial family. This title, generally translated “born in the purple,” either refers to the purple robes in which the imperial children were wrapped at birth, or to a chamber or part of the imperial palace, called the Porphyra (πόρφυρα), where the births took place. Whether this Porphyra signifies a chamber or a purple hangings or lined with porphyry is not known (see Selden, Tides of Honour, ed. 1672, p. 60 seq).

PURPURA, in pathology, a general term for the symptom of purple-coloured spots upon the surface of the body, due to extravasations of blood in the skin, accompanied occasionally with haemorrhages from mucous membranes. The varieties of purpura may be conveniently divided as follows: (a) toxic, following the administration of certain drugs, notably copaiba, quinine, ergot, belladonna and the iodides; also following snake-bite; (b) cæhetic, seen in persons suffering from such diseases as tuberculosis, heart disease, cancer, Bright’s disease, jaundice, as well as from certain of the infectious fevers, extravasations of the kind above mentioned being not infrequently present; (c) neurotic; (d) arthritic, which includes the form known as “Purpura simplex,” in which there may or may not be articular pain, and the complaint is usually ushered in by lassitude and feverishness, followed by a change of discoloration on the surface of the body of the characteristic spots in the form of small red points scattered over the skin of the limbs and trunk. The spots are not raised above the surface, and they do not disappear on pressure. Their colour soon becomes deep purple or nearly black; but after a few days they undergo the changes which are observed in the case of an ordinary bruise, passing to a green and yellow hue and finally disapppearing. When of minute size they are termed “petechiae” or “stigmata,” when somewhat larger “vibices,” and when in patches of considerable size “ecchymoses.” They may come out in fresh crops over a lengthened period.

Purpura rheumatica (Schöneid’s disease) is a remarkable variety characterized by sore throat, fever, pain in the joints, and headache, accompanied by urticae and occasionally with definite nodular infiltrations. This is by many writers considered to be a separate disease, but it is usually regarded as rheumatic origin.

Haemorrhagic purpura (acute haemorrhagic purpur) is a more serious form, in which, in addition to the phenomena already mentioned as affecting the skin, there is a tendency to the occurrence of haemorrhage from mucous surfaces, especially from the nose, but also from the mouth, lungs, stomach, bowels, kidneys, &c., sometimes in large and dangerous amount. Great physical prostration is apt to attend this form of the disease, and a fatal result sometimes follows the successive haemorrhages, or is suddenly precipitated by the occurrence of an extravasation of blood into the brain.
PURRAH—PURVEYANCE

The treatment will bear reference to any causes which may be discovered as associated with the onset of the disease, such as unfavorable hygienic conditions, and nutritive defects should be rectified by suitable diet. The various preparations of iron seem to be the best medicinal remedies in this ailment, while more direct astringents, such as gallic acid, ergot of rye, turpentine or acetate of lead, will in addition be called for in severe cases and especially when haemorrhage occurs. Sir A. Wright considers that in all cases of purpura the coagulation-time of the blood should be estimated. In such cases the time taken for clotting may be increased to three times as long as that taken by normal blood. He therefore advises calcium chloride in order to increase coagulability. In severe haemorrhages, adrenaline is often useful.

PURRAH, PURRAH, or PUROR, a secret society of Sierra Leone, West Africa. Only males are admitted to its ranks, but two other affiliated and secret associations exist, the Yassil and the Bundu, the first of which is nominally reserved for males, but members of the Purrah are admitted to certain ceremonies. All the female members of the Yassil must be also members of the Bundu, which is strictly reserved to women. Of the three, the Purrah is by far the most important. The entire native population is governed by its code of laws. It primarily represents a type of freemasonry, a "friendly" society to which even infants are temporarily admitted, the ceremony in their case consisting merely of carrying them into the Purrah "bush" and out again. But this side of the Purrah is merged in its larger objects as represented by its two great aspects, the religious and the civil. Under the former, boys join it at puberty, while under the latter it is practically the native governing body, making laws, deciding on war and peace, &c.

The Purrah has its special ritual and language, tattooing and symbols, but details are unknown, as the oath of secrecy is always kept. It meets usually in the dry season, between the months of October and May. The rendezvous is in the "bush," an enclosure, separated into apartments by mats and roofed only by the overhanging trees, serving as a club-house. There are three grades, the first for chiefs and "big men," the second for fetish-priests and the third for the crowd. The ceremonies of the Purrah are presided over by the Purrah "devil," a man in fetish dress, who addresses the members of a Purrah in a language that they understand.

The Purrah can place its taboo on anything or anybody; and as no native would venture to defy its order, much trouble has been caused where the taboo has been laid upon crops. In 1897 the British or local government was compelled to pass a special ordinance absolutely forbidding the imposition of the taboo on all indigenous products. Of the affiliated societies the Yassil appears to some extent to be an association for providing men and women, who believe themselves ill through "fetish," with medical treatment, on payment of certain fees. The women's Bundu is in many ways a replica of the men's Purrah, though without political power.

PURSE (Late Lat. bursa, adapted from Gr. βόσπορος, hide, skin; possibly O. Eng. puza, bag, has influenced the change from b to p), a small bag for holding money, originally a leather pouch tied at the mouth, but now of various shapes. The great seal of England is borne by the purse-bearer in a purse, usually styled "purse," decorated with the arms of the kingdom, the "purse," being thus one of the insignia of office of the lord chancellor of England. The "privy purse" is the amount of public money set apart in the civil list for the private and personal use of the sovereign (see Purveyor).

PURSER, the old name for the paymaster of the British and American navies still used in merchant vessels of to-day. In the British navy he was appointed by a warrant from the admiralty and was paid partly by salary and partly by a percentage (10%) on the value of unexpended stores.

PURSLANE, the common name for a small fleshy annual with prostrate stems, entire leaves and small yellow flowers, known botanically as Portulaca oleracea. It is a native of India, which was introduced into Europe as a salad plant, and in some countries has spread so as to become a noxious weed. In certain parts of the United States the evil qualities of "puddy" have become proverbial. Its juice is refreshing and is used in tropical countries as a refrigerant in fever. Some of the species of the same genus, such as P. grandiflora and its varieties, are grown in gardens on rock-work owing to the great beauty and deep colouring of their flowers, the short duration of individual blossoms being compensated for by the abundance with which they are produced.

PURSUIVANT (O. Fr. persiant, pursiant, mod. pursuant, strictly an attendant, from poursuivre, to follow), the name of a member of the third and lowest rank of heraldic officers, formerly an attendant on the heralds. There are four pursuivants in the English Herald's College, Rouge Croix, Bluemantle, Rouge Dragon and Portcullis; three in the Court of Lyon King of Arms (Scotland), Carrick, Unicorn and March; and four in the Court of Ulster King of Arms (Ireland), Athlone and three St Patrick pursuivants. (See Herald and Heraldry.)

PURVEYANCE (Lat. providere, to provide), in England in former times the right of the sovereign when travelling through the country to receive food and drink and maintenance generally from his subjects for himself and his retinue. The custom dates from Anglo-Saxon times and is analogous to the right of fodrum, or annona militaris, exercised by the Frankish kings. Although in early times purveyance was reasonable and necessary, enabling the king to make journeys for the purpose of administering justice and discharging the other duties of government, it was liable to grave abuses, and under the later Plantagenet kings it became very oppressive. Provision for the royal needs was interpreted in the widest possible sense, and the right was exercised, not only on behalf of the king, but on behalf of his relatives. Besides victuals it included the compulsory use of horses and carts and even the enforcement of personal labour.

Not infrequently no payment was made; when it was it often took the form of tallies, which gave the recipient the right to deduct the amount from any taxes he might have to pay in the future. Purveyors were appointed to requisition goods, and they also fixed the price. The abuses of purveyance, which appear to have reached their climax during the reign of Edward I., frequently provoked legislation. Chapter xxviii. of Magna Carta is directed against them, while further attempts to curb them were made in the Statute of Westminster of 1275 and in the Articuli super cartas of 1300. Purveyance was entirely forbidden by the ordinance of 1311, but in spite of all prohibitions its evils grew and flourished. During the reign of Edward III. ten statutes were directed against it, and by a law of 1366 it was restricted to the personal wants of the king and queen; at the same time the hated name of purveyor was changed to that of buyer, and ready money was ordered to be paid for the articles taken. From this time little was heard about the evils of purveyance until 1604, when the House of Commons petitioned James I., giving some striking illustrations of its hardships. It was asserted that when the royal officials required 200 carts they ordered 800 or 900 to be brought, in order that they might obtain bribes from the owners. Bacon called purveyance "the most common and general abuse of all others in the kingdom." Twice James entered into negotiations with his parliament for commuting his crown rights, of which purveyance was one, for an annual payment, but no arrangement was reached. In 1660, however, the right of purveyance, which had fallen into disuse during the executions of Charles I., was surrendered by Charles II. in return for the grant of an excise on beer and liquors. The custom was exercised by almost all European sovereigns, and in France at least was as oppressive as in England. The word purveyor now means merely a vendor, generally a vendor of food and drink.

PUSA, a village of British India, in Darbanga district, Bengal, near the right bank of the Burbi Gandak River; pop. (1901), 4,750. It was acquired as a government estate in 1796, and was long used as a stud dépôt and afterwards as a tobacco farm. In 1904 it was selected as the site of a college and laboratory for agricultural research.

PUSEY, EDWARD BOUVIERIE (1800–1882), English divine, was born at Pusey near Oxford on the 22nd of August 1800. His father was Philip Bouvierie (d. 1828), a younger son of Jacob Bouvierie, 1st Viscount Folkestone, and took the name of Pusey, on succeeding to the manorial estates at that place. After having been at Eton, he became a commoner of Christ Church, Oxford, and was elected in 1824 to a fellowship at Oriel. He thus became a member of a society which already contained some of the ablest of his contemporaries—among them J. H. Newman and John Keble. Between 1825 and 1827 he studied Oriental languages and German theology at Göttingen. His first work, published in 1828, as an answer to Hugh James Rose's Cambridge lectures on rationalist tendencies in German theology, showed a good deal of sympathy with the German "pietists," who had striven to deliver Protestantism from its decadence; this sympathy was misunderstood, and Pusey was himself accused of holding rationalist views.

In the same year (1828) the duke of Wellington appointed him to the regius professorship of Hebrew with the attached canony of Christ Church. The misunderstanding of his position led to the publication in 1830 of a second part of Pusey's Historical Enquiry, in which he denied the charge of rationalism. But in the years which immediately followed the current of his thoughts began to set in another direction. The revolt against individualism had begun, and he was attracted to its standard. By the end of 1833 he showed a disposition to make common cause with those who had already begun to issue the Tracts for the Times. He was not, however, fully assenting to the movement till 1835 and 1836, when he published his tract on baptism and started the Library of the Fathers" (Newman's Apologia, p. 136). He became a close student of the fathers and of that school of Anglican divines who had continued, or revived, in the 17th century the main traditions of pre-Reformation teaching. A sermon which he preached before the university in 1843, The Holy Eucharist a Comfort to the Penitent, so startled the authorities by the re-statement of doctrines which, though well known to ecclesiastical antiquaries, had faded from the common view, that by the exercise of an authority which, however legitimate, was almost obsolete, he was suspended for two years from the function of preaching. The immediate effect of his suspension was the sale of 18,000 copies of the condemned sermon; its permanent effect was to make Pusey for the next quarter of a century the most influential person in the Anglican Church, for it was one of the causes which led Newman to sever himself from that communion. The movement, in the actual origination of which he had no share, came to bear his name: it was popularly known as Puseyism (sometimes as Newmania) and its adherents as Puseyites. His activity, both public and private, as leader of the movement was enormous. He was not only on the stage but also behind the scenes of every important controversy, whether theological or academical. In the Gorham controversy of 1830, in the question of Oxford reform in 1834, in the prosecution of some of the writers of Essays and Reviews, especially of Benjamin Jowett, in 1863, in the question as to the reform of the marriage laws from 1849 to the end of his life, in the Farrar controversy as to the meaning of everlasting punishment in 1877, he was always busy with articles, letters, treatises and sermons. The occasions on which, in his turn, he preached before his university were all memorable; and some of the sermons were manifestoes which mark distinct stages in the history of the Church. "He "poured it on thick and fast." The practice of confession in the Church of England practically dates from his two sermons on The Entire Absolution of the Penitent, in 1846, in which the revival of high sacramental doctrine is complemented by the advocacy of a revival of the penitential system which medieval theologians had appended to it. The sermon on The Presence of Christ in the Holy Eucharist, in 1853, first formulated the doctrine round which almost all the subsequent theology of his followers revolved, and which revolutionized the practices of Anglican worship. Of his larger works the most important are his two books on the Eucharist—The Doctrine of the Resurrection (1855) and The Real Presence...the Doctrine of the English Church (1857); Daniel the Prophet in which he endeavours to maintain the traditional date of that book; The Minor Prophets, with Commentary, his chief contribution to the study of which he was the professor; and the Eirenicon, in which he endeavoured to find a basis of union between the Church of England and the Church of Rome.

In private life Pusey's habits were simple almost to austerity. He had few personal friends, and rarely mingled in general society; though bitter to opponents, he was gentle to those who knew him, and his munificent charities gave him a warm place in the hearts of many to whom he was personally unknown. In his domestic life he had some severe trials; his wife died, after eleven years of married life, in 1839; his only son, who was a scholar like-minded with himself, who had shared many of his literary labours, and who had edited an excellent edition of St Cyril's commentary on the minor prophets, died in 1880, after many years of suffering. From that time Pusey was seen by only a few persons. His strength gradually declined, and he died on the 18th of September 1882, after a short illness. He was buried at Oxford in the cathedral of which he had been for fifty-four years a canon. In his memory his friends purchased his library, and bought for it a house in Oxford, known as the Pusey House, which they endowed with sufficient funds to maintain three librarians, who were charged with the duty of endeavouring to perpetuate in the university the memory of the principles which he taught.

Pusey is chiefly remembered as the eponymous representative of the earlier phase of a movement which carried with it no small part of the religious life of England in the latter half of the 19th century. His own chief characteristic was an almost unbounded capacity for taking pains. His chief influence was that of a preacher and a spiritual adviser. As a preacher he lacked all the graces of oratory, but compelled attention by his searching and practical earnestness. His correspondence as a spiritual adviser was enormous; his deserved reputation for piety and for solidity of character made him the chosen confessor to whom large numbers of men and women unburdened their doubts and their sins. But if he be estimated apart from his position as the head of a great party, it must be considered that he was more a theological antiquary than a theologian. Pusey in fact was left behind by his followers even in his lifetime. His revival of the doctrine of the Real Presence, coinciding as it did with the revival of a taste for medieval art, naturally led to a revival of the Pre-Reformation ceremonial of worship. With this revival of ceremonial Pusey had little sympathy: he first protested against it (in a university sermon in 1859); and, though he came to defend those who were accused of breaking the law in their practice of it, he did so on the express ground that their practice was alien to his own. But this revival of ceremonial in its various degrees became the chief external characteristic of the new movement; and "Ritualist" thrust "Puseyite" aside as the designation of those who held the doctrines for which he mainly contended. On the other hand, the pivot of his teaching was the appeal to primitive antiquity; and in this respect he helped to start inquiry which has since gone far beyond the materials which were open to one of his generation.

See J. Rigg, Character and Life-Work of Dr Pusey (1883); B. W. Savile, Dr Pusey, an Historic Sketch, with Some Account of the Oxford Movement (1883), and especially The Life by Canon Liddon, completed by J. C. Johnston and R. J. Wilson (5 vols., 1893–1899), Newman's Apologia, and other literature of the Oxford Movement.

Pusey's elder brother, PHILIP PUSEY (1799–1855), was a member of parliament and a friend and follower of Sir Robert Peel. He was one of the founders of the Royal Agricultural Society, and was chairman of the implement department of the great exhibition of 1851. He was a fellow
of the Royal Society, a writer on varied topics to the "reviews and the author of the hymn "Lord of our Life and God of our Salvation."

**PUSHBALL**, a game played by two sides on a field usually 140 yds. long and 50 yds. wide, with a ball 6 ft. in diameter and 50 lb. in weight. The sides usually number eleven each, there being five forwards, two left-wings, two right-wings and two goal-keepers. The goals consist of two upright posts 18 ft. high and 20 ft. apart with a crossbar 7 ft. from the ground. The game lasts for two periods with an interpolation. Pushing the ball under the bar counts 5 points; lifting or throwing it over the bar counts 8. A touchdown behind goal for safety counts 2 to the attacking side. The game was invented by M. G. Crane, of Newton, Massachusetts, in 1804, and was taken up at Harvard University the next year, but has never attained any considerable vogue. In Great Britain the first regular game was played at the Crystal Palace in 1902 by teams of eight. The English rules are somewhat different from those obtaining in the United States.

**PUSHKIN** (1799-1837), Russian poet, was born at Moscow on the 7th of June 1799. He belonged to an ancient family of boyars; his maternal great-grandfather, a favourite negro ennobled by Peter the Great, bequeathed him curly hair and a somewhat darker complexion than falls to the lot of the ordinary Russian. In 1811 the future poet entered the newly founded lyceum of Tsarokoe Selo, situated near St. Petersburg. On quitting the lyceum in 1817 he was attached to the ministry of foreign affairs, and in this year he began the composition of his **Ruslan and Lyudmila**, a poem which was completed in 1820. Meanwhile Pushkin mixed in all the gayest society of the capital, and it seemed as if he would turn out a mere man of fashion instead of a poet. But a very daring **Ode to Liberty** written by him had been circulated in manuscript in St. Petersburg. This production having been brought to the notice of the governor, the young author only escaped a journey to Siberia by accepting an official position at Kishinev in Bessarabia, in southern Russia. If we follow the chronological order of the poet's life, the enthusiasm with which he greeted the ever-changing prospects of the sea and the regions of the Danube and the Crimea.

At this time Pushkin was, or affected to be, overpowered by the Byronic "Welschmerz." Having visited the baths of the Caucasus for the re-establishment of his health in 1822, he felt the inspiration of its magnificent scenery, and composed **The Prisoner of the Caucasus**, narrating the story of the love of a Circassian girl for a youthful Russian officer. This was followed by the **Fountain of Bakhchisarai**, which tells of the detention of a young Polish captive, a Countess Potocka, in the palace of the khans of the Crimea. About the same time he composed some interesting lines on Ovid, whose place of banishment, Tomi, was not far distant. To this period belongs also the **Ode to Napoleon**, which is inferior to the fine poems of Byron and Manzoni, or indeed of Lermontov, on the same subject. In the **Lay concerning the rise of Odes** we see how the influence of Karamzin's **History** had led the Russians to take a greater interest in the early records of their country. The next long poem was the **Gipseis** (Tzuigani), an Oriental tale of love and vengeance, in which Pushkin has admirably delineated these nomads, whose strange mode of life fascinated him. During his stay in southern Russia he allowed himself to get mixed up with the secret societies then rife throughout the country. He also became embroiled with his chief, Count Vorontzov, who sent him to report upon the damages which had been committed by locusts in the southern part of Bessarabia. Pushkin took this as a premeditated insult, and sent in his resignation; and Count Vorontzov in his official report requested the government to remove the poet, "as he was surrounded by a society of political and literary fanatics, whose praises might turn his head and make him believe that he was a great writer, whereas he was only a feeble imitator of Lord Byron, an original not much to be commended." The poet quitted Odessa in 1824, and on leaving wrote a fine **Ode to the Sea**. Before the close of the year he had returned to his father's seat at Mikhailovskoe, near Pavlov, where he soon isolated himself in trouble on all sides. In his retirement he devoted a great deal of time to the study of the old Russian popular poetry, the **radus**, of which he became a great admirer. Recollections of Byron and Andre Chenier gave the inspiration to some fine lines consecrated to the latter, in which Pushkin appeared more conservative than was his wont, and wrote in a spirit antagonistic to the French Revolution. In 1825 he published his tragedy ** Boris Godunov**, a bold effort to imitate the style of Shakespeare. Up to this time the traditions of the Russian stage, such as it was, had been French.

In 1825 the conspiracy of the Dekabrists broke out. Many of the conspirators were personal friends of Pushkin, especially Kichelbecker and Pushchin. The poet himself was to a certain extent compromised, but he succeeded in getting to his house at Mikhailovskoe and burning all the papers which might have been prejudicial to him. Through influential friends he succeeded in making his peace with the emperor, to whom he was presented at Moscow soon after his coronation. The story goes that Nicholas said to Count Bludov on the same evening, "I have just been conversing with the most witty man in Russia!" In 1826 appeared **Polzua**, a spirited narrative poem, in which the expedition of Charles XII. against Peter and the treachery of the hetman Mazeppa were described. In 1829 Pushkin again visited the Caucasus, on this occasion accompanying the expedition of Prince Paskevich. He wrote a pleasing account of the tour; many of the short lyrical pieces suggested by the scenery and associations of his visit are delightful, especially the lines on the Don and the Caucasus. In 1831 Pushkin married Natalia Goncharova, and in the following year was again attached to the ministry of foreign affairs, with a salary of 5000 roubles. He now busied himself with an historical account of the revolt of the Cossack Pugachev, who almost overthrew the empire of Catherine and was executed at Moscow in the latter part of the 18th century. While engaged upon this he wrote **The Captain's Daughter**, one of the best of his prose works. In 1832 was completed the poem **Eugene Onegin**, in which the author remade the whole style of Byron in the Italian manner. Yet no one can accuse Pushkin of want of nationalism in this poem: it is Russian in every fibre.

In 1837 the poet, who had been long growing in literary reputation, fell mortally wounded in a duel with Baron George Heckeren d'Anthes, the adopted son of the Dutch minister then resident at the court of St. Petersburg. D'Anthes, a vain and frivolous young man, had married a sister of the poet's wife. Notwithstanding this he aroused Pushkin's jealousy by some attentions which he paid Natalia; but the grounds for the poet's anger, it must be confessed, do not appear very great. Pushkin died, after two days' suffering, on the afternoon of Friday the roth of February. D'Anthes was tried by court-martial and expelled the country. In 1850 a statue of the poet was erected at the Tver Barrier at Moscow, and fêtes were held in his honour, on which occasion many interesting memorials of him were exhibited to his admiring countrymen and a few foreigners who had congregated for the festivities. Pushkin left four children; his widow was afterwards married to an officer in the army, named Lanskoj; she died in 1865.

Pushkin's poetical tales are spirited and full of dramatic power. The influence of Byron is undoubtedly seen in them, but they are not imitations, still less is anything in them plagiarized. **Boris Godunov** is a fine tragedy; on the whole **Eugene Onegin** must be considered Pushkin's masterpiece. Here we have a great variety of styles—satire, pathos and humour mixed.
together. The character-painting is good, and the descriptions of scenery introduced faithful to nature. The poem in many places reminds us of Byron, who himself in his mixture of the pathetic and the humorous was a disciple of the Italian school. Pushkin also wrote a great many lyrical pieces. Interspersed among the poet’s minor works will be found many epigrams, but some of the best composed by him were not so fortunate as to pass the censorship, and must be read in a supplementary volume published at Berlin. As a prose writer Pushkin has considerable merits. Besides his History of the Revolt of Pugachev, which is perhaps too much of a compilation, he published a small volume of tales under the pseudonym of Ivan Byelkin. These all show considerable dramatic power: the best are The Captain’s Daughter, a tale of the times of Catherine II.; The Undertaker, a very ghostly story, which will remind the English reader of some of the tales of Edgar Poe; The Pistol Shot; and The Queen of Spades.

The academy of St Petersburg has recently issued a complete edition of the works of Pushkin, including his letters. See the bibliography in the editions of Genadli (7 vols., St Petersburg, 1861) and Annenkov (6 vols., St Petersburg, 1855).

PUSHTU, the language of the Pathan races of Afghanistan and the North-West Frontier province of India. It belongs to the Iranian group of the Indo-European languages, but possesses many Panjabi words. In Afghanistan it is the dominant language, but is not spoken west of the Helmund. In India it has two main dialects, the northern, hard or Pukhtu, and the southern, soft or Pushtu. The dividing line of the two dialects runs eastwards from Thal through the Kohat district almost to the Indus, but it then turns northwards, as the speech of the Akhora Khattaks belongs to the Pushtu or southern dialect. Thus Pukhtu is spoken in Bajaur, Swat and Buner, and by the Yusufzais, Bangash, Orakzais, Afridis and Mohmands; while Pushtu is spoken by the Waziris, Khattaks, Marwats and various minor tribes in the south. The language division corresponds roughly with the tribal system of the Pathans, who are aristocratic in the north and democratic in the south. The classical dialect of Pukhtu is that of the Yusufzais, in which the earliest works in the language were composed. The Orru dialect differs from that of the Afridis, in that it is broader but less guttural and spoken more rapidly. The standard dialect is that of Peshawar. The literature is richest in poetry, Abdur Rahman, of the 17th century, being the best-known poet. Pushtu was spoken in the North-West Frontier province in 1901 by 1,142,011 persons, or 44% of the population.

See Grierson, Linguistic Survey of India; Roos-Keppe, Manual of Pushtu (1901); Lorimer, Grammar of Wastri Pushtu (1902).

PUTEAUX, a north-western suburb of Paris, on the left bank of the Seine, 4½ m. from the centre of the city. Pop. (1906), 28,718. Puteaux has a church of the 16th century with good stained glass windows. There is a fort on the Seine.

PUTEOLI (mod. Pozzuoli, q.v.), an ancient town of Campania, Italy, on the northern shore of the Bay of Puteoli, a portion of the Bay of Naples, from which it is 6 m. W. The statement made by Stephanus of Byzantium and Jerome, that the city was founded under the name of Dicearchia by a colony of Samians about 520 B.C., is probably correct, for though the territory of Cumae, it does not appear to have been occupied previously to the Musaeum at the original port of Cumae. On the other hand, Cumaean probably extended her supremacy over it not long after. Its history in the Samnite period is unknown; but the coins of Festina (or Fistus in Oscan) probably belong to Puteoli, as Mommssen thought. Nor do we know anything of its history between 334 (when it probably became a civitas sine suffragio under Roman domination, shortly afterwards receiving, in 318, a praefectus iure dicundo) and 215, when the Romans introduced a garrison of 6,000 men to protect the town from Hannibal, who besieged it in vain for three days in 214. In 194 a Roman colony of 300 men was established. The Lex juridic. factiune, an interesting inscription of 105 B.C. relating to some building works in front of the temple of Serapis, shows that Puteoli had considerable administrative independence, including the right to date such a public document by the names of its own magistrates. Sulla retired to Puteoli after his resignation of the dictatorship in 79, and ten days before his death reconciled the disputes of the citizens by giving them a constitution. Cicero had a house in Puteoli itself, and a villa on the edge of the Lucrine lake (which, though nearer to Puteoli, was in the territory of Cumae), and many prominent men of the republic possessed country houses in the neighbourhood of Puteoli (see Baja; Avérnus Lacus; Lucrinus Lacus; Misenum). In the Civil War it sided with Pompey, and later on with Brutus and Cassius. Nero admitted the old inhabitants to the privileges of the colony, thus uniting in one the two previously distinct communities. In 61 St Paul landed here, and spent seven days before leaving for Rome (Acts xxviii. 13). Vespasian, as a reward for its having taken his part, gave the town part of the territory of Capua, and installed more colonists there—whence it took the title Colonia Flavia, which it retained till the end of the empire.

The remains of Hadrian, who died at the neighbouring town of Baja, were buried at Puteoli, and Antoninus Pius, besides erecting a temple to his memory on the site of Cicero’s villa, instituted sacred games to be held in the city every five years. Commodus held the title of duumvir quinquennalis. It was mainly, however, as a great commercial port that Puteoli was famous in ancient times. It joined with Naples to erect one of the finest porticoes of Constantinople at the time of its construction. A letter of Symmachus gives us interesting details as to public corn distributions of the 4th century, throwing some light on the population. Like Ostia, Puteoli was considered a special port of Rome, and, on account of the safety and convenience of its harbour, it was preferred to Ostia for the landing of the more costly and delicate wares. As at Ostia, the various guilds were of considerable importance, but we find no centonarii or fabri, perhaps owing to its relations with the East, where these popular guilds were prohibited. Puteoli was preferred to Naples, (a) as being in Roman territory, (b) because the customs duty was only payable once, not twice as it would have been at Naples—once by the local authorities, and once by the Roman authorities on entrance into Roman territory! It exported iron from Elba, mosaics, pottery, manufactured locally with earth from Ischia (which was in considerable demand until 1883), sulphur (which indeed was extracted in the neighbourhood until the 18th century), probably alum (which is still worked), perfumes, pozzolana earth (taking its name from the place), cretaceous earth for mixing with grain (aleco) from the Leucogaean hills, glass cups engraved with views of Puteoli, mineral dyes (the blue invented by one Vestorius is mentioned by Vitruvius and the purple of Puteoli by Pliny, as being of special excellence), &c., but not agricultural products, except certain brands of Campanian wine; but its imports were considerably greater. During the Punic Wars it was still a naval port, but in the latter part of the 2nd century B.C. it became the greatest commercial harbour of Italy and we find Lucilius about 125 B.C. placing it next in importance to Delos, then the leading port of the ancient world.

We note a little later the existence of merchants of Puteoli in the East. Under the empire we find Eastern cults taking root here sooner than in Rome. The construction of the harbour of Claudius at the mouth of the Tiber adversely affected Puteoli. Nero’s scheme for the construction of a canal from Lake Avernus to Ostia would have restored the balance in its favour (though it certainly could not have been continuous all the way to Rome with the means of engineering then available).

The corn supply of Rome came partly through Puteoli, partly through Ostia. Seneca (Epist. 77) describes the joy of the inhabitants in the spring when the fleet of corn vessels from Alexandria was seen approaching, and Statius tells us that the crew of the ship which arrived first made libations to Minerva as soon as to the local manufacturer. Some fragments came from Arretium, others, not quite so good, were of local work, but of the same style.
when passing the promontory which bore her name (the Punta Campanella at Sorrento). It is uncertain what official had the charge of the corn supply at Puteoli under the Republic, but in the time of Antoninus Pius, we read an Aug(usti) dis(pensæ) a frumento Puteolis et Ostis dependent no doubt on a procurator annoneae of the two ports.

Claudius established here, as at Ostia, a cohort of vigiles as a fire-brigade. Brundisium was similarly protected. There was also a station of the imperial post, sailors of the imperial fleet at Misenum being apparently employed as couriers. The artificial mole was probably of earlier date than the reign of Augustus (possibly 2nd century B.C.); and by that time at any rate there were docks large enough to contain the vessels employed in bringing the obelisks from Egypt. Remains of the piles of the mole still exist, and are popularly known as Caligula's Bridge, from the mistaken idea that they belong to the temporary structure which that emperor flung across the bay from the mole at Puteoli to the shore at Baiae. Inscriptions record repairs to the breakwater by Antoninus Pius in 139 in fulfilment of a promise made by Hadrian before his death. Alaric (410), Goths (415 and 554) successively laid Puteoli in ruins. The restoration effected by the Byzantines was partial and short-lived.

The original town of Puteoli was situated on the narrow hill of the Castello. Scanty traces of fortifications of the Roman period seem to have come to light in recent tunnelling operations. The streets of the Roman period as at Nîmes, are preserved. There are traces of the division of the lands in the immediate vicinity of the town into squares by parallel paths (decuman and cardines) at regular intervals of 1111 Roman feet, portions of which were to be built up. The colonnades remained, but the Roman feet, divided into 81 smaller squares—an arrangement which could not have existed at Puteoli, and must have arisen elsewhere. It is remarkable as being contrary to Roman surveyors' practice, according to which the basis of division is the intersection at right angles (cardo and decumanus), with the number of squares (an old) number of smaller squares. The size of the ancient town at its largest can be roughly fixed by its tombs. Inscriptions show that it was divided into regions. The market hall (macellum) was surrounded by buildings up to a height of three stories. The columns still standing, some 39 ft. high, belong to the façade of four still higher columns erected in front of the absidal cela or sanctuary, with three niches for statues—no doubt of the principal deities of the cult. Portions of the shells of marine shells visible in these columns between 11 and 19 ft. from the ground, and the various levels of pavement in the macellum help to indicate, according to Günther's researches (Archaeologia, L. 499), Earth Movements in the Bay of Naples, that there was upheaval during the Roman period, when it was some 20 ft. higher than at present; that it fell more rapidly during the middle ages, was then raised again early in the 16th century (before the upheaval of the Macellum was finished); and has since been sinking radially. In the centre was a round colonnade with sixteen columns of Numidian marble (giusto antico) now in the theatre of the palace at Caserta. Dubois (op. cit., 386 sqq.) reproduces important drawings and a description made by the architect Cariste in 1820. The well preserved amphitheatre, the subterranean parts of which below the arena are intact, with a main passage down the centre, a curved passage all round with holes for trap doors in its roof, and numerous small chambers, also with trap doors in their vaulted roofs for admitting the wild beasts, and passages for the attendants. The walls of the arena, are especially interesting. There were also arrangements for flooding the arena, but these can only have been in use before the construction of the greater part of the subterranean portion with its temporary covering. The largest part of the arena is 245 by 138 ft. Of the upper portion the interior is well preserved, but very little of the external arcades remains. It was not constructed before the reign of Vespasian, for inscriptions record that the Colossus of Nero was erected there. This was the amphitheatre in the reign of Nero, who himself fought in games given there, and the glass cup of Oedemira shows two. A ruin still exists which may be doubtfully attributed to the latter (Dubois, p. 102). The other amphitheatres of the Bay of Naples having been much used in Roman times. The cathedral of S. Proculus (containing the tomb of the musician Pergolesi, d. 1736) is built into a temple of Augustus, erected by L. Calpurnius, 6 columns of which, with a larger portion of capitals, still exist. Of the ruins—of a circus of tombs, &c., exist, and there are also considerable remains of villas in the neighbourhood.

Puteoli was supplied with water by two aqueducts, both subterranean, one of which, bringing water from springs in the immediate neighbourhood, is still in use, while the other is a branch of the Serino aqueduct, which was probably taken to Misenum by Agrippa. Several remains of reservoirs exist; one very large one is now called Puteoli, P. Cardito.

Among the inscriptions one of the most interesting is the letter of the Tyrian merchants resident at Puteoli to the senate of Tyre, written in 174, asking the latter to undertake the payment of the rent of their houses, and the reply of the senate promising to do so. (This is the interpretation adopted by Dubois, pp. 86-92, followed by Dittenberger.) We find other Eastern merchants resident here—merchants from Heliopolis, Berytus (Beirut), Nabataea, Palestine, and from Asia Minor, Greece, &c. We find far less trace of commercial relations with the West, though there was considerable importation of commodities from southern Spain—wine, oil, metals, salt, fish, &c., while a good deal of pottery was exported to Spain and Rome. The health of the city was also important, as is evidenced by the presence of men who held municipal honours at Puteoli, who are listed in the Rhone, a valley. Puteoli was reached direct by a road from Capua traversing the hills by a cutting (the Montagna Spaccata), which went on to Neapolis, and by the Via Domitiana from Rome and Cumae. There was also a route from Puteoli to Neapolis by the tunnel of Pauspilium, made under Augustus. It is not possible to trace the episcopal see of Puteoli with any certainty further back than the beginning of the 4th century. In 305, S. Januarius (S. Gennaro, the patron saint of Neapolis), was killed by Alaric, the ruler of Puteoli, and others, suffered martyrdom at Puteoli.

See the careful study by C. Dubois, Fouilles antiques (Paris, 1897) (Bibliothèque des écoles françaises d'Athènes et de Rome, fasc. 98.)

(847. A.)

PUTLITZ, GUSTAV HEINRICH GANS, EDLER ZU (1821-1890), German author, was born at Retzien near Perleberg in West Pruginitz, on the 20th of March 1821. He studied law at Berlin and Heidelberg, and was attached to the provincial government at Magdeburg from 1846-1848. In 1853 he married Gräfin Elisabeth von Königsmark, and lived on his estate until 1863, when he became director of the Court theatre at Schwerin. This post he held in 1867, was for a short time chamberlain to the crown prince of Prussia, afterwards the emperor Frederick, and from 1873 to 1889 successfully directed the Court theatre at Karlsruhe. He died at Retzien on the 5th of September 1890. Putlitz made his debut as a writer with a volume of romantic stories, Was sich der Wald erzählt (1850), which attained great popularity (fifty editions) and found many imitators; but he was most successful in his comedies, notably Badkuren (1859); Das Herz vergessen (1853); and Spiel nicht mit dem Feuer (1857), while of his narratives Die Alpenbraut (1870) and Walpurgis (1870) are distinguished by refined terseness of style and delicacy of portraiture.

Among his works, Ausgewählte Werke, was published in 6 vols. (Berlin, 1883-1890). A play of his, which was produced in 1852, and in which, of all his works, his characters, Oedemira (1851-1860 and 1869-1872). See E. zu Putlitz, Gustav zu Putlitz. Ein Lebensbild aus Briefen (3 vols., 1894-1895).

PUTNAM, ISRAEL (1718-1790), American soldier, was born in Salem Village (now Danvers), Massachusetts, on the 7th of January 1718. His first American ancestor (of the same family as George Puttenham), came from Aston Abbotts, Bucks, and was one of the first settlers of Salem Village. In 1740 he removed to a farm in the present townships of Pomfret and Brooklyn, Connecticut. Here in the winter of 1742-1743 he went down into a wolf den (still shown in Pomfret) and at close quarters killed a huge wolf. Putnam took an active part in the French and Indian War, enlisting as a private in 1755 and rising to the rank of major in March 1758. He was conspicuous for personal courage and for skill in Indian warfare, and was the hero of numerous exploits. In 1764, during Pontiac's conspiracy, he commanded the Connecticut troops (five companies) in the expedition under Colonel John Bradstreet for the relief of Detroit. He was a prominent member of the Sons of Liberty and a leader in the opposition to the Stamp Act; was elected to the general assembly of Connecticut in 1766 and 1767; and increased his political influence by opening a tavern, "The General Wolfe," in Brooklyn, Conn. In August 1774, as chairman of the committee of correspondence for Brooklyn parish, he went with the committee's message and contributions to the Boston Patriots; and in October became lieutenant-colonel of the 11th regiment of Connecticut militia. News of the fighting at
Lexington and Concord reached him while he was ploughing on his farm; he instantly left the plough in the furrow and hastened to Cambridge; and he was later made second brigadier of the Connecticut forces. He was with the force, commanded by Colonel William Prescott, which on the night of the 16th of June fortified Breed's Hill, and on the next day he took a conspicuous part in resisting the British attack (see Bunker Hill). Soon afterward, on his own authority, he occupied Prospect Hill, an important point for the siege of Boston, in which he commanded the centre (two brigades) of the American army at Cambridge. After the evacuation of Boston he was in command of New York City till Washington's arrival (April 13, 1776), and then was put in general charge of the city's fortifications. Immediately before the battle of Long Island he succeeded General John Sullivan in command of the troops on Brooklyn Heights, and misconduct or negligence in connexion with the loss of Fort Montgomery and Clinton. After a few months' recruiting service in Connecticut he commanded one of the three grand divisions, and took part in the battle of Harlem Heights (September 16). His attempt to close the Hudson by sinking vessels in the channel was unsuccessful. In December he was ordered to Philadelphia to superintend the fortification of the city, was stationed at Princeton, New Jersey, from January to May 1777, and in May took command of the Hudson Highlands at Peekskill, which with Forts Montgomery and Clinton he abandoned in October, being out-maneuvered by the British, and having been weakened by Washington's repeated demands for reinforcements. In the spring of 1778 he was superseded by General Alexander McDougall, but in April a court of inquiry acquitted him of any fault, misconduct or negligence in connexion with the loss of Forts Montgomery and Clinton. After a few months' recruiting service in Connecticut he returned to the main army at White Plains. In the winter of 1778-1779 he commanded the troops quartered near Redding, Conn., where Putnam Memorial Park now is. In May he took command of the right wing on the west side of the Hudson. An attack of paralysis in December 1779 terminated his active service in the war. He spent his last years on his farm in Brooklyn, Conn., where he died on the 29th of May, 1824. A bronze equestrian statue by Karl Gerhardt, over 12 ft. high, and surrounded by a sarcophagus, was erected at Brooklyn, Conn., by the state in 1888, and there is another statue (1874) in Bushnell Park, Hartford, by J. Q. A. Ward.

Putnam was a brave, intrepid and very industrious soldier rather than a great general, but his family, the Indians, his personal courage, his bluff bearing, and his good-fellowship made him an idol of the rank and file; and he is one of the popular heroes in American history. He seems to have taken no part in the political manœuvrings and cabals which busied many of the officers of the American army.

See W. F. Livingston, Israel Putnam, Pioneer, Ranger and Major-General (New York, 1901) in the "American Men of Energy" series; I. N. Tarbox, Life of Israel Putnam (Boston, 1876); and Essay on the Life of the Honorable Major-General Israel Putnam (Harford, 1888; enlarged ed., Boston, 1818), by David Humphreys, for a time Putnam's aide-de-camp.

PUTNAM, RUFUS (1738-1824), American soldier and pioneer, was born in Sutton, Massachusetts, on the 9th of April 1738 (O.S.). His grandfather was a half brother to Israel Putnam's father. He served in the French and Indian War in 1757-60, was a millwright in New Braintree in 1761-1768, during which time he studied surveying; and from 1769 until the War of Independence was a farmer and surveyor. In 1773, with Israel

Putnam and two others, he visited West Florida to examine lands which, it was expected, were to be granted to the provincial troops for their services against the French and Indians, and which he charted (see MississippI). He became lieutenant-colonel in one of the first regiments raised after the battle of Lexington, and served before Boston; in March 1776 he was made chief engineer of the works at New York; in August he was appointed engineer with the rank of colonel; and when Congress did not act on his plan (submitted in Oct. 1776) for the establishment of a distinct engineer corps he resigned (Dec. 1776), and in 1777 served in the northern army under Major-General Horatio Gates, commanding two regiments in the second battle of Saratoga. In 1778 he laid out fortifications, including Fort Putnam, at West Point, and in 1779 he served under Major-General Anthony Wayne after the capture of Stony Point. For the remainder of the war he saw little active service. In January 1783 he was commissioned brigadier-general. After the war he returned to Rutland, Mass., where he bought a confiscated farm in 1780. In March 1786 he founded, with other officers of the War of Independence, the Ohio Company of Associates for the purchase and settlement of Western lands. In November 1787, after Congress had made its grant to the Ohio Company, he was appointed by the company superintendent of its proposed settlement on the Ohio, and in 1788 he led the small party which founded Marietta, Ohio. He was a judge of the court of the North-West Territory in 1790-1796; was a brigadier-general in the army and a commissioner to treat with the Indians in 1792-1793; was surveyor-general of the United States in 1796-1803; and in 1802 was a member of the Ohio state constitutional convention. He died, in Marietta, on the 4th of May 1824. He has been called "The Father of Ohio," and he contributed greatly toward the material building up of the North-West Territory.

See John W. Campbell, Biographical Sketches (Columbus, Ohio, 1838); Sidney Crawford, "Rufus Putnam, and his Pioneer Life in the North-West," vol. xii., new series, pp. 431-454, Proceedings of the Ohio Historical Society, ed. by H. P. Buell (Columbus, 1899); and Rufus Putnam (Boston, 1903), in which his autobiography, his journal and other papers, now in the library of Marietta College, are reprinted. His Journal, 1777-1780, dealing with his experiences in the French and Indian War, was edited with notes by E. C. Dacew (Albany, New York, 1886).

PUTNAM, a city and the county-seat of Windham county, Connecticut, U.S.A., in the township of Putnam, on the Quinebaug river, at the mouth of the Mill river, in the N.E. part of the state. Putnam, from the Rhode Island boundary and about 7½ m. from that of Massachusetts. Pop. (1900), of the township (including the city), 7348; of the city, 6665; (1910) 6637. Putnam is at the intersection of two branches of the New York, New Haven & Hartford railway, and is connected by electric line with Worcester, Norwich and Providence. The city is the seat of two Roman Catholic institutions, St. Mary's Convent and Notre Dame Academy, and has a public library and an endowed hospital. The Quinebaug and Mill rivers provide excellent water-power. The township (named in honour of General Israel Putnam) was incorporated in 1855, and the city was chartered in 1895.

PUTTEE, or Putte, the name, adapted from the Hindi putti, bandage (Skrd. patta, strip of cloth), for a covering for the lower part of the leg from the ankle to the knee. A narrow piece of cloth wound tightly and spirally round the leg, and serving both as a support and protection, worn especially by riders, and taking the place of the leather or cloth gaiter. It has been adopted as part of the uniform of the mounted soldier in the British army.

PUTTENHAM, GEORGE (d. 1590), the reputed author of The Arte of English Poesie (1580). The book was entered at Stationers' Hall in 1588, and published in the following year with a dedicatory letter to Lord Burghley written by the printer Richard Field, who professed ignorance of the writer's name and position. There is no contemporary evidence for the authorship, and the name of Puttenham is first definitely associated with it in the Hypercritica of Edmund Bolton, published in 1722, but
PUTTING THE SHOT—PUTTKAMMER

written in the beginning of the 17th century, perhaps as early as 1605. The writer of the Arte of English Poetie supplies certain biographical details. He was educated at Oxford, and at the age of eighteen he addressed an encomium entitled Elpice to Edward VI. In his youth he had visited Spain, France and Italy, and was better acquainted with foreign courts than with his own. In 1579 he presented to Queen Elizabeth his Porthetriades (printed in a collection of MSS. Ballads by F. J. Furnivall), and he wrote the treatise in question especially for the delectation of the queen and her ladies. He mentions nine other works of his, none of which are extant. There is no direct evidence beyond Bolton's ascription to identify the author with George or Richard Puttenham, the sons of Robert Puttenham and his wife Margaret, the sister of Sir Thomas Elyot, who dedicated his treatise on the Education or Bringing up of Children to her for the benefit of her sons. Both made unhappy marriages, were constantly engaged in litigation, and were frequently in disgrace. Richard was in prison when that book was intended to be written, in which he made his will in 1597 he was in the Queen's Bench Prison. He was buried, according to John Payne Collier, at St. Clement Danes, London, on the 2nd of July 1601. George Puttenham is said to have been implicated in a plot against Lord Burghley in 1570, and in December 1578 was imprisoned. In 1585 he received reparation from the privy council for alleged wrongs suffered at the hands of his relations. His will is dated the 1st of September 1590. Richard Puttenham is known to have spent much of his time abroad, whereas there is no evidence that George ever left England. This agrees better with the writer's account of himself; but if the statement that he addressed Elpice to Edward VI, when he was eighteen years of age be taken to imply that the production of this work fell within that king's reign, the date of the author's birth cannot be placed anterior to 1529. At the date (1546) of his inheritance of his grandfather, Sir Thomas Elyot's estates, Richard Puttenham was young; and so was an inspection held at Newmarket to have been twenty-six years old.

Whatever the author may have been, there is no doubt about the importance of the work, which is the most systematic and comprehensive treatise of the time on its subject. It is "contrived into three bookes: the first of poetes and poezies, the second of proportion, the third of ornament." The first section contains a general history of the art of poetry, and a discussion of the various forms of poetry; the second treats of prosody, dealing in turn with the measures in use in English verse, the caesura, punctuation, rhyme, accent, cadence, "proportion in figure," which the author illustrates by geometrical diagrams, and the proposed innovations of English quantitative verse; the section on ornament deals with style, the distinctions between written and spoken language, the figures of speech; and the author closes with lengthy observations on good manners. It is interesting to note that in his remarks on language he deprecates the use of archaism, and although he allows that the purer Saxon speech is spoken beyond the Trent, he advises the English writer to take as his model the usual speech of the court, of London and the home counties.

Many later "poetics" are indebted to this book. The original edition is very rare. Professor Edward Arber's reprint (1866) contains a clear summary of the various documents with regard to the authorship of this treatise. It contains a reprint of the 16th edition of Elyot's Boke called the Gouernour. A careful investigation brought him to the conclusion that the evidence was in favour of Richard. There are other modern editions of the book, notably one in J. Haslwood's Ancient Critical Essays (1841-1845).

PUTTING THE SHOT (or WEIGHT), a form of athletic sports (q.v.). It is the only weight event now remaining in the championship programme which requires a "put," as distinct from a throw. A put being a fair and square push straight from the shoulder, quite distinct from throwing or bowling, which are not allowed in putting the shot. The exercise originated in Great Britain, where, before the formation of the Amateur Athletic Association, the shot (a round weight of 16 lb) was put from a jost about 8 ft. with a run of 7 ft., the distance being measured from the impression made by the falling missile to the point on the joist, or a line continuing it, opposite the impression. Hence the putter failed to get the full benefit of any put save a perfectly straight one. The present British rule is that the put shall be made from a 7-ft. square, and the distance taken from the first pitch of the shot to the front line of the square or that line produced, as by the old method. In America the put is made from a 7-ft. circle, and the distance measured from the pitch to the nearest point of the circle, which has a raised edge in front to prevent overstepping and consequent fouls. Individual putters have slight variations of method, but the following description is substantially good for all. The putter stands in the back part of the square or circle with his weight entirely upon his right leg, which is bent. The body is inclined slightly backward, the left arm stretched out in front as a balance, and the right hand, the shot resting in the palm, is held against, or an inch or two from, the neck below and behind the right ear. From this position a hop forward with the right leg, the foot landing in the middle of the square and the balance being preserved, so that the right shoulder is kept well back. Then, letting the right leg bend well down, the athlete springs up with a rapid twist of the body, so that the right shoulder is brought forward, and the right arm thrust forward with all possible force, the secret being to throw all the weight and power of the body and arm into the put at the very moment of delivery. Mere brute strength and weight have less to do with successful shot-putting than hammer-throwing or throwing the 56-lb weight, and on this account some comparatively light men have repeatedly beaten larger and taller putters. Thus G. R. Gray, a Canadian by birth, who for many years held the world's record of 47 ft. for the 16-lb shot, was a smaller and less powerful man than several whom he defeated; and another champion of light weight was W. F. Robertson of Scotland, who weighed only 150 lb. Among the best putters of earlier times were E. J. Bor, London Athletic Club, who made a put of 42 ft. 5 in. in 1872; W. Y. Winthrop, and G. Ross. The talent of Irish athletes both in Great Britain and America for weight putting and throwing is remarkable, among the most famous of Irish putters being W. J. McBarry and Denis Hogan, the latter of whom won the amateur championship in seven consecutive years from 1893, and again in 1902 and 1905. The record in 1910 for the 16-lb shot was 51 ft. made at_SFUTTKAMMER, ROBERT VON (1828-1900), Prussian statesman, was born at Frankfort-on-the-Oder on the 3rd of May 1828. His father, Eugen von Puttkammer, Oberpräsident of Posen, belonged to a widely extended noble family, of which Bismarck's wife and Robert von Puttkammer's own wife were also members. Robert von Puttkammer, after a short course of law, began his official career in 1850 as Auskultator in the courts at Danzig, but in 1852 entered the civil service, receiving after his promotion to the rank of Assessor in 1854 a post in the railway department of the ministry for trade and industry. In 1856 he became a member of the presidial council (Oberpräsidentschaft) at Coblenz, capital of the Prussian Rhine province, and from 1860 to 1866 was Landrat at Demmin in Pomerania. During the war with Austria he acted as civil commissary in Moravia. From 1867-1868 to 1871 he was a councillor in the chancery of the North German Confederation. In 1871 he was appointed president of the governmental district of Gumbinnen in East Prussia, in 1875 district president (Bezirkspräsident) in Lorraine, and in 1877 Oberpräsident in Silesia. From 1874 onward he was frequently elected to the Reichstag and the Prussian Chamber of Deputies, in which he attached himself to the German Conservative party. Puttkammer was the chosen instrument of the Clerical Conserva- tive policy initiated by Bismarck when the Socialists peril made a specific election campaign against the Catholic candidate. In 1882-83 the Prussian Oberpräsident of Silesia he had already done much to mitigate the rigour of the application of the "May Laws," and as minister of public worship and of the interior he continued this policy. He is also remembered as the author of the ordinance of the 21st of January 1880 on the simplification of German orthography. This was at first vigorously opposed, not least by Bismarck himself; but its
PUTTY—PUVIS DE CHAVANNES

convenience soon became evident, it was increasingly put into practice, and was so well based that later reformers have only needed to follow the lines laid down by Puttkammer. As minister of the interior Puttkammer's activities were less commendable. His reactionary conservative temper was in complete harmony with the views of Bismarck and the emperor William, and with their powerful support he attempted, in defiance of modern democratic principles and even of the spirit of the constitution, to re-establish the old Prussian system of rigid discipline from above. He was above all concerned to nip in the bud any tendencies in the bureaucracy to revolt, and it was on his initiative that, on the 4th of January 1882, a royal ordinance laid it down as the duty of all officials to give the government their unconditional support at political elections. Similarly, though he carried out many useful administrative reforms, in a vain effort to combat Social Democracy he seriously interfered with the liberty of public meeting and attempted the forcible suppression of strike movements. The Puttkammer regime was intensely unpopular; it was attacked in the Reichstag not only by Radicals like Richter and Rickert, but by National Liberals like Bennigsen, and when the emperor Frederick III., whose liberal tendencies were notorious, succeeded to the throne, it was clear that it could not last. In spite of Bismarck's support Puttkammer was forced to resign on the 8th of June 1888. Under William II., however, whose principles were those of his grandfather, Puttkammer was largely rehabilitated. On the 1st of January 1889 he received the Order of the Black Eagle. He was appointed a secular canon (Domherm) of Merseburg, and in 1891 became Oberpräsident of Prussian Pomerania. In this office, which he held till 1899, he did very useful work in collaboration with the provincial estates. He died on his property at Karzin in Pomerania on the 15th of March 1900. (J. H. N.)

PUTTY, originally tin oxide in a state of fine division used for polishing glass, granite, &c., and known as "putty powder" or "putty." (from O. Fr. pâte, a paste, hence brass, tin, pewter, &c., calcined in a pot.) More commonly the term is applied to a kind of cement composed of fine powdered chalk intimately mixed with linseed oil, either boiled or raw, to the consistency of a tough dough. It is principally used by glaziers for bedding and fixing sheets of glass in windows and other frames, and by joiners and painters for filling up nail-holes and other inequalities in the surface of woodwork. The oxidation of the oil gradually hardens the putty into a very dense adherent mass, but when it is required to dry quickly, boiled oil and sometimes vitriol and other driers are used. The word is also used of a fine lime cement employed by masons.

PUVIS DE CHAVANNES, PIERRE CÉCILE (1824—1898), French painter, was born at Lyons on the 14th of December 1824. His father was a mining engineer, the descendant of an old family of Burgundy. Pierre Puvis was educated at the Lyons College and at the Lycée Henri IV. in Paris, and was intended to follow his father's profession when a serious illness interrupted his studies. A journey to Italy opened his mind to fresh ideas, and on his return to France he announced his intention of becoming a painter, and went to study first under Henri Scheffer, and then under Couture. On leaving this master in 1852 he established himself in a studio in the Place Pigalle (which he did not give up till 1897), and there organized a sort of academy for a group of fellow students who wished to work from the living model. Puvis first exhibited in the Salon of 1850 a "Pitié," and in the same year he painted "Mademoiselle de Sombreuil Drinking a Glass of Blood to Save her Father," and "Jean Cavalier by his Mother's Deadbed," besides an "Ecce Homo," now in the church of Champagnat (Saône-et-Loire). In 1852 and in the two following years Puvis's pictures were rejected by the Salon, and were sent to a private exhibition in the Galerie Baudry at Nîmes. The public laughed at his work as loudly as at that of Courbet, but the young painter was none the less warmly defended by Théophile Gautier and Théodore de Banville. For nine years Puvis was excluded from the Salons. In 1857 he had painted "Martyrdom of St Sebastian," "Meditation," "Village Firemen," "Julie," "Herodias," and "Saint Camilla"—compositions showing a great variety of impulse, still undecided in style and reflecting the influence of the Italian masters as well as of Delacroix and Couture. In 1859 Puvis reappeared in the Salon with the "Return from Hunting" (now in the Marseilles Gallery). But not till he produced "Peace" and "War" did he really impress his critics, inaugurating a vast series of decorative paintings. For these two works a second-class medal was awarded to him, and the state offered to purchase the "Peace." Puvis, not choosing to part the work, made a gift of "War" to the state. He then set to work again, and in 1864 exhibited "Autumn" and "Sleep," but found no purchasers. One of these pictures is now in the Lyons Museum, and the other at Lille. "Peace" and "War" were placed in the great gallery of the museum at Amiens, where Puvis completed their effect by painting four panels—a "Standard-Bearer," a "Woman Weeping over the Ruins of her Home," a "Reaper," and a "Woman Spinning." These works were so much admired that further drawings and eight months for the same building, and the artist presented to the city of Amiens "Labour" and "Repose," for which the municipality could not afford to pay. At their request Puvis undertook another work, intended for the upper landing of the staircase, and in 1865 a composition entitled "Ave Picardia Nutrix," allegorical of the fertility of the province, was added to the collection. In 1879 the city wished to complete the decoration of the building, and the painter, again at his own expense, executed the cartoon of "Ludus pro patria," exhibited in the Salon of 1881 and purchased by the state, which at the same time gave him a commission for the finished work. While toiling at these large works, Puvis de Chavannes rested himself by painting easel pictures. To the salon of 1870 he had sent a picture called "Harvest;" the "Beheading of John the Baptist" figured in the Great Exhibition of 1851; then followed "Hope" (1872), the "Inn of the Fisher Girls" (1873), and "We see your Sea shore" (1879). But these canvases, however interesting, are not to be named by the side of his grand decorative works. Two paintings in the Palais Longchamp at Marseilles, ordered in 1867, represent "Marseilles as a Greek Colony" and "Marseilles, the Emporium of the East." After these, Puvis executed for the town-hall of Poitiers two decorative paintings of historical subjects: "Ragged," and "Charles Martel." The Panthéon in Paris also possesses a decorative work of great interest by this painter: "The Life of Saint Genèviève," treated in three panels. In 1876 the Department of Fine Arts in Paris gave the artist a commission to paint "Saint Genèviève giving Food to Paris," and "Saint Genèviève watching over Sleeping Paris," in which he gave to the saint the features of Princess Cantacuzene, his wife, who died not long before he did. At the time of his death—on the 24th of October 1898—the work was almost finished. After completing the first paintings in the Panthéon, Puvis de Chavannes undertook to paint the staircase leading to the gallery of fine arts in the Lyons Museum, and for this subject the "Vision of the Antique," a procession of youths on horseback, which a female figure standing on a knoll points out to Phidian; the "Sacred Grove;" and two allegorical figures of "The Rhône" and "The Saône." It was in the same mood of inspiration by the antique that he painted the hemicycle at the Sorbonne, an allegory of "Science, Art, and Letters," a work of great extent, for which he was paid 35,000 francs (£1,400). At the Hôtel de Ville in Paris, again, Puvis decorated the great staircase and the first reception-room. These works employed him from 1889 till 1893. In the reception-room he painted two panels, "Winter" and "Summer," the mural paintings on the staircase, which had previously been placed in the hands of Baudry and of Delaunay, are devoted to the glory of the attributes of the city of Paris and of the provinces which have rendered his lyre to the city of Paris. The pictures in the Rouen Museum (1890-1892) show a different vein, and the artist's power of conceiving and setting forth a plastic scheme enabling him to decorate a public building with beautiful human figures and the finest lines of landscape. We see here toilers raising a...
colossal monolith, part of some ancient monument, to add it to other architectural pieces; then the busy scene of a pottery, and finally artists painting in the open air. Puvìs, as a rule, adhered to the presentment of the nude or of the lightest drapery; here, however, in response to some critical remarks, he has clad his figures exclusively in modern dress. After prolonged negotiations, the Frans, however, the most remarkable engravings and etchings of the period, formed a definite plan with the Victoria and Albert Library, U.S.A., Puvìs de Chavannes accepted a commission to paint nine large panels for that building, to be inserted in separate compartments, three facing the door, three to the right and three to the left. These pictures, begun in 1895, were finished in 1898.

In these works of his latest period Puvìs de Chavannes soars boldly above realistic vision. In the figures which people the walls with poetic images he endeavours to achieve originality of the embodying forms, and at the same time a plastic expression of ideas born of a mind whose conceptions grew ever loftier, while yet the artist would not abandon the severe study of nature. Such works as the great paintings at Amiens, Rouen, Marseilles, the Panthéon, the Sorbonne, and the Hôtel de Ville are among the most important productions of French art in the 19th century. Puvìs de Chavannes was president of the National Society of Fine Arts in 1886, and the New Salon. His principal followers are Ary Renan (d. 1900), Baudouin, J. F. Auburtin and Cottet.

See A. Michel, "Exposition de M. Puvìs de Chavannes," Gazette des beaux-arts (1888); Marius Vachon, Puvìs de Chavannes (1900); J. Buisson, "Puvìs de Chavannes, Souvenirs Intimes," Gazette des beaux-arts (1899).

PUY, a geological term used locally in Auvergne for a volcanic hill. Most of the puys of central France are small cinder-cones, with or without associated lava, whilst others are domes of trachytic rock, like the domite of the Puy-de-Dôme. The puys may be scattered as isolated hills, or as more usual, clustered together, sometimes in lines. The chain of puys in central to north central to east central France is described in last chapter. Other volcanic hills more or less like those of Auvergne are also known to geologists as puys; examples may be found in the Eifel and in the small cones on the Bay of Naples, whilst the relics of denuded puys are numerous in the Swabian Alps of Württemberg, as pointed out by W. Branco. Sir A. Geikie has shown that the puy type of eruption was common in the British area in Carboniferous and Permian times, as abundantly attested in central Scotland by remains of the old volcanoes, now generally reduced by denudation to the mere neck, or volcanic vent, filled with tuff and agglomerate, or plugged with lava.

See Sir A. Geikie, Ancient Volcanoes of Great Britain (1897).

PUY-DE-DÔME, a department of central France, four-fifths of which belonged to Basse-Auvergne, one sixth to Bourbonnais, and the remainder to Forez (Lozérais). Area, 3046 sq. m. (1906), 353,410. It is bounded N. by Allier, E. by Loire, S. by Haute-Loire and Cantal, and W. by Corrèze and Creuse. The highest point of the department, the Puy de Sancy (6188 ft.), is also the most elevated peak of central France; it commands the group of the volcanic Monts Dore, so remarkable for their rocky corries, their erosion valleys, their trap dykes and orgues of basalt, their lakes sleeping in the depths of ancient craters or confined in the valleys by streams of lava, and their wide plains of pasture-land. The Puy de Sancy, forming part of the watershed, gives rise on its northern slope to the Dordogne, and on the east to the Couze, a sub-tributary of the Loire, through the Allier. The Monts Dore are joined to the mountains of Cantal by the volcanic group of the Cézallier, of which the highest peak, the Lugnet (5102 ft.), rises on the confines of Puy-de-Dôme and Cantal. On the north the Monts Dore are continued by a plateau of a mean height of from 3000 to 3500 ft., upon which are seen sixty cones raised by volcanic outbursts in former times. These are the Monts Dômes, which extend south as far as Riom, the largest remaining being the Puy-de-Dôme (4800 ft.), from which the department takes its name, and the Puy-de-Parieu, the latter having a crater more than 300 ft. in depth. A meteorological observatory occupies the summit of the Puy-de-Dôme, which was once crowned by a Roman temple, the ruins of which still exist. To the east of the department, along the confines of Loire, are the Monts du Forez, rising to 5380 ft. and continued north by the Bois Noirs. Between these mountains and the Dôme extends the fertile plain of Limagne. The drainage of Puy-de-Dôme is divided between the Loire, by its affluents the Allier and the Cher, and the Gironde, by the Dordogne. The Allier traverses the department from south to north, and in the Allier it divides the territory into the Allier at the northern boundary and lowest level of the department (879 ft.); on its left are the Alagnon from the Cantal, the two Couzes from the Lugué and the Monts Dore, and the Sioule, the most important of all, which drains the north-west slopes of the Monts Dore and Dôme, and joins the Allier beyond the limits of the department. The Cher forms for a short space the boundary between the departments of Puy-de-Dôme and Creuse, close to that of Allier. The Dordogne, while still scarcely formed, flows past Mont-Dore-les-Bains and La Bourboule and is lost in a deep valley which divides this department from that of Corrèze. None of these streams is navigable, but boats can be used on the Allier during floods. The climate of Puy-de-Dôme is usually very severe, owing to its high level and its distance from the sea; the mildest air is found in the northern part, and the greatest snowfalls in the central and north-western parts. The inhabitants in the department are described as healthy by Geikie, whose account of them is based on that by Bourquelot, who has written a few lines to pay due tribute to the quality about Clermont-Ferrand, exposed to the sun, become all the hotter because their black volcanic soil absorbs its rays. On the average 25 or 26 in. of rain fall in the year; in the Limagne around which the mountains arrest the clouds rainfall is less. Nevertheless the soil of this plain, consisting of alluvial deposits of volcanic origin, and watered by torrents and streams from the mountains, makes it one of the richest regions of France. In the highest altitudes the rainfall attains 64 in.

About two-thirds of the inhabitants of Puy-de-Dôme are engaged in agriculture. The Limagne yields a variety of products and the vine flourish on its hill-sides. The high mountains provide pastures for large flocks of cows and sheep, and cheese-making is an industry of much importance. The intermediate region is cultivated chiefly for cereals, the chief of which are rye, wheat, oats and barley. Potatoes are largely grown, and, to a lesser extent, peas, beans, and colza. The Limagne produces fruits of all kinds—apricots, cherries, pears, walnuts and apples, from which considerable quantities of cider are made. The department possesses considerable mineral wealth. There are important coal-mines at Brassac on the Allier, on the borders of Haute-Loire, at St. Eloy near the department of Allier, and at Bourg-Lastic on the borders of Corrèze. Peat, asphalt, bituminous schists, antimony, mica, and argentiferous lead are also worked. The department of Allier produces also large quantities of yellow ochre, used for tanning. None of the four departments of Mont Dore, Royat and La Bourboule receive separate notice. The department of Mont Dore, like that of Haute-Loire, contains large mineral districts, for there are found so many springs which produce large quantities of cheap cutlery, paper and leather, and Clermont-Ferrand, the capital. The department contains factories for lace and braid (in the mountains), for butting and camlets and wool, cotton and hemp mills. There are also large ironworks, producing iron, cast-iron, ironware, copper-plates, also silk-mills, tanneries, manufactories for chamois and other leathers, for caoutchouc (Clermont-Ferrand), sugar-works, manufactories of edible pastes with a reputation as high as those of Italy, olive oil, jams and confections, fruit-preserves. The department exports grain, fruits, cattle, wines, cheese, wood, mineral waters, cutlery, &c. It is served by the Orléans and Paris-Lyon railway companies. Many thousands of the inhabitants, belonging chiefly to the district of Auvergne, who resided in it during the Middle Ages, but elsewhere as notables, chimney-sweeps, pit-sawyers, &c. The department comprises 35 arrondissements—Clermont-Ferrand, Ambert, Issoroe, Riom, Thiers—50 cantons and 471 communes. It is included in the historic province of Auvergne (canton), but it is included also in the region of the XI. army corps, of which the headquarters are in the same town; the appeal court is at Riom.

The more noteworthy places in the department are Clermont-Ferrand, Issoroe, Thiers, Riom, Ambert, Mont-Dore-les-Bains, La Bourboule and Royat (all separately noticed). Near Clermont-Ferrand is Mont Gergovie (see Gergovie) the scene of the victory of Vercingetorix over Julius Caesar. Other places of
interest are Billom, Chamalières, Courpière, Orcival, St Nectaire, and St Saturnin, which possess churches in the Romanesque style of Auvergne. There are ruined feudal strongholds of great interest at Murols and Tourniol (near Volvic). Vic-le-Comte has a sainte-chapelle which is a beautiful example of the transition from Gothic to Renaissance architecture, and Aigueperse has a Gothic church of the 13th to the 15th century. Near Pontgibaud are the ruins (14th century) of the Carthusian abbey of Port St Marie.

PUYLAURENS, ANTOINE DE LAAGE, DUC DE (d. 1633), French courtier, was born of an old Languedoc family. Attached to the household of Gaston, duke of Orleans, brother of Louis XIII., he gained a complete ascendancy over the weak prince by pandering to his pleasures, and became his adviser in the intrigues against Cardinal Richelieu. It was Puylaurens who arranged the escape of Gaston to Brussels in 1632 after the capture of Henri, duc de Montmorency, and then negotiated his return with Richelieu, on condition that he should be reconciled to the king. As a reward Richelieu gave him Aiguillon, erected into a duchy. But he plunged into new intrigues, and was imprisoned first in the Louvre in 1635, then in Vincennes, where he died in 1638.

PUZZLE, a perplexing question, particularly a mechanical toy or other device involving some constructional problem, to be solved by the exercise of patience or ingenuity. Some of the oldest mechanical puzzles are those of the Chinese, one of the most familiar being that known as the tangram (chi chiao t'ue), which consists of a square of wood or other material cut into five triangles, of different sizes, a small square and a lozenge, which can be so placed as to form over 300 different figures. This puzzle is sometimes made of ivory carved with the delicate workmanship for which the Chinese craftsmen are renowned, and is enclosed in a carved box. Another well-known puzzle is known as the "Chinese rings," consisting of a series of rings running linked together on a bar, the problem being to take them off the bar and replace them. The commonest of all puzzles are coloured maps, pictures ("jig-saw") or designs, dissected into numerous variously shaped pieces, to be fitted together to form the complete design. A great number of puzzles are based on mathematical principles, such as the "fifteen puzzle," the "railway shunting puzzle," and the like.

See W. W. Rouse Ball, Mathematical Recreations and Amusements: (1892).

The etymology of the word "puzzle" is disputed. It has been usual to consider that the verb, which appears first at the end of the 16th century, is derived from the substantive, and that this is an aphetic form of "apposal" or "opposal" i.e. opposition, hence a question for solution, cf. Lydgate, Fall of Princes, quoted by Skeat, in Etrym. Dict. 1898. The New English Dictionary, however, takes it as clear from the chronological evidence and sense-development that the substantive is derived from the verb, which, in its earliest examples, means to put in embarrassing material circumstances, to bewilder, to perplex. This seems against making "to puzzle" a derivative of "to pose," i.e. "oppose," to examine by putting questions. Some connexion may be found with a much earlier word "pooseit," confused, bewildered, which does not occur later than the end of the 14th century.

PWLHELL ("salt pit," or "pool"), a municipal and contributory parliamentary borough (Carnarvon district), seaport and market-town of Carnarvonshire, North Wales, 20 m. S. of Carnarvon and 270 m. from London by rail. Pop. (1901), 2,675. It is on the north side of Cardigan Bay, on the shore of Tremadoc Bay, with a sandy beach 4 m. in length and good bathing. It is the terminus of the Cambrian railway (the London & North-Western railway being 4 m. distant at Afonwen junction). Pwllheli commands a good view of Merionethshire and of the Snowdon range, with the entire sweep of Cardigan Bay, Carreg yr ymbell (gimlet stone) at the mouth of the harbour, Aberosch and St Tudwal's Islands. Many hundred acres of land have been reclaimed from the sea here and along the coast of the bay; there are costly embankments and good harbourage. The coast is locally noted for fisheries (especially of lobsters and oysters) and some ship-building is carried on. Pwllheli was incorporated by Edward the Black Prince. At Nevin (Nevyn), 6 m. distant, Edward I. held a tournament or revel, in 1284, on a magnificent scale, to commemorate his conquest of Wales.

PYANEPSIA, or PYANOPSSA (from Gr. πιανός = κλαυμος, bean, and ἐπει, to boil), an ancient festival in honour of Apollo, held at Athens on the 7th of the month Pyanepsis (October). A hodge-podge of pulse was prepared and offered to Apollo (in his capacity as sun god and ripener of fruits) and the Horae, as the first-fruits of the autumn harvest. Another offering on this occasion was the eireisōné. This was a branch of olive or laurel, bound with purple or white wool, round which were hung various fruits of the season, pastries, and small jars of honey, oil and wine. It was intended as a thank-offering for blessings received, and at the same time as a prayer for similar blessings and protection against evil in future; hence, it was called a "suppliant" branch (xkrynpia). The name is generally derived from ἐπος (wool) in reference to the woolen bands, but some connect it with ἐπει (to speak), the eireisōné being regarded as the "spokesman" of the suppliants. It was carried in procession by a boy whose parents were both alive to the temple of Apollo, where it was suspended on the gate. The doors of private houses were similarly adorned. The branch was allowed to hang for a year, when it was replaced by a new one, since by that time it was supposed to have lost its virtue. During the procession a chant (also called eireisōné) was sung, the text of which has been preserved in Plutarch (Theseus, 22):—

"Eireisōné carries figs and rich cakes; Honey and oil in a jar to anoint the limbs; And pure wine, that she may be drunken and go to sleep."

The semi-personification of eireisōné will be noticed; and, according to Mannhardt, the branch "embodies the tree-spirit conceived as the spirit of vegetation in general, whose vivifying and fruitifying influence is thus brought to bear upon the corn in particular."

Aetologists connected both offerings with the Cretan expedition of Theseus, who, when driven ashore at Delos, vowed a thank-offering to Apollo if he slew the Minotaur, which afterwards took the form of the eireisōné and Pyanopsia. To explain the origin of the hodge-podge, it was said that his comrades on landing in Attica gathered up the scraps of their provisions that remained and prepared a meal from them.

See W. Mannhardt, Wald- und Feldkunde (1860), ii. 214, for an exhaustive account of the eireisōné and its analogies; J. G. Frazer, The Golden Bough (1900), i. 190; J. E. Harrison, Prolegomena to Greek Religion (1908), ca. 3: L. R. Farnell, Cults of the Greek States (1907), iv. 286.

PYAPON, a town and district of Lower Burma. The town is situated on a river of the same name, one of the numerous mouths of the Irrawaddi, about 12 m. from the sea. Pop. (1901), 585. The district, which was only formed in 1893, lies within the delta of the Irrawaddi. It is a vast plain, intersected by tidal creeks and subject to inundation at high spring tides. The swampy jungle is being rapidly reclaimed for rice cultivation, which is the sole crop. Area, 2,137 sq. m.; pop. (1901), 226,443, showing an increase of 63% in the decade.

PYAT, FELIX (1818-1886), French Socialist, was born at Vierzon (Cher) on the 4th of October 1818, the son of a Legitimist lawyer. Called to the bar in Paris in 1831, he threw his whole energies into journalism. The violent personalities of a pamphlet entitled Marie Joseph Chénier et le prince des critiques (1844), in reply to Jules Janin, brought him a six months' sojourn in La Pélage, in the cell just quitted by Lamennais. He worked with other dramatists in a long series of plays, with an interval of six years on the National, until the revolution of 1848. George Sand, whom he had introduced in 1830 to the staff of the Figaro, now asked Ledru-Rollin to make him commissary-general of the Cher. After three months' tenure of this office he was returned by the department to the Constituent Assembly, where he voted with the Mountain, and brought forward the celebrated motion for the abolition of the presidential office. About this time he fought a duel with Proudhon, who

PUYLAURENS—PYAT
had called him the "aristocrat of the democracy." He joined Ledru-Rollin in the attempt of the 13th of June 1849, after which he sought refuge in Switzerland, Belgium, and finally in England. For a glorification of regicide on the occasion of the Orsini attempt against Napoleon III, he was brought before an English court, but acquitted, and the general amnesty of 1860 permitted his return to France, but further outbursts against the authorities, followed by prosecution, compelled him to return to England. The revolution of the 4th of September brought him back to Paris, and it was he who in his paper *Le Combat* displayed a black-edged announcement of the *pourparlers* for the surrender of Metz. After the insurrection of the 31st of October he was imprisoned for a short time. In January 1871, *Le Combat* was suppressed, only to be followed by an equally virulent *Vengeur*. Elected to the National Assembly, he retired from Bordeaux with Henri Rochefort and others until such time as the "parcellar" vote for peace should be annulled. He returned to Paris to join the committee of public safety, and, in Hanotaux's words, was the *demeuré* of the Commune, but was blamed for the loss of the fort of Issy. He was superseded there by Delescluze, but he continued to direct the violent acts of the Commune, the overthrow of the Vendôme column, the destruction of Thiers's residence and of the exiatory chapel built to the memory of Louis XVI. He escaped the vengeance of the Versailles government, crossed the frontier in safety, and, though he had been condemned to death in his absence in 1873, the general amnesty of July 1880 permitted his return to Paris. He was returned to the Chamber of Deputies for the department of Bouches-du-Rhône in March 1888 and took his seat on the extreme Left, but died at Saint-Gratien on the 3rd of August 1880.

**PYATIGORSK**, a town and watering-place of Russian Caucas, in the province of Terek, 141 m. by rail N.W. of Vladikavkaz. Pop. (1882), 13,679; (1897), 18,682. It owes its origin to its mineral waters, which have long been known to the inhabitants of Caucas. The sulphur springs, about fifteen in number, come from a great depth, and vary in temperature from 75° to 96° F.; they are used both for drinking and for bathing. The first buildings were erected in 1812, and in 1830 the name of Pyatigorsky ("town of the five mountains") was given to the new settlement. Its subsequent rapid increase was greatly stimulated by the completion of the railway connexion with Rostov-on-the-Don. The town is charmingly situated on a small plateau, 1680 ft. above sea-level, at the foot of the Beshtau, Mashuk and three other outliers of the Caucasus range, which protect it on the north. The snow-covered summits of the Elbruz are visible to the south. The most noteworthy features are a cathedral, a monument to the poet M. Y. Lermontov (1814-1841), and a hydro-pathic.

**Pycnogonida**, or *Pantopoda*, marine Arachnida (q.v.) remarkable for the reduction of the opisthosoma or abdomen to an insignificant tubercular or rod-like process (whence their trivial name of "nobody crabs"), and for the development of the oral region into a relatively immense suctorial proboscis. The form a compact group, differing from all the other genera of Arachnida in certain structural characters of such morphological importance that it is impossible to affiliate them closely with any group of that class. For instance, in all typical existing Arachnida the ganglionic centres which innervate the ambulatory appendages are coalesced to form a single nervous mass, whereas in the Pycnogonida the ganglia supplying these limbs retain their original distinctness. More important still is the circumstance that in the Pycnogonida there may be as many as seven pairs of leg-like limbs behind the mouth; but in the typical Arachnida there are never more than five such pairs. Curiously enough, too, although the number of these appendages in all the orders of typical Arachnida is, with the exception of some degenerate Acari, a quite constant character, the number in the Pycnogonida is very variable. In most cases there are four pairs of ambulatory limbs, but in two antarctic genera, namely *Pentanymphon*, belonging to the family Nymphonidae and *Decapoda*, probably belonging to the Colossendeidae, they are increased to five pairs. In front of these four or five pairs of ambulatory limbs there may be two pairs of longish post-oral limbs, called respectively the ovigerous legs and the palpi; but these may be totally absent. Finally, the single pair of pre-oral appendages may be well developed, three-jointed and chelate, or reduced in size and complexity, or altogether suppressed.

![Fig. 1.—Male of *Pycnogonum littorale*, Müller.](image1)

(a, Parts of mouth forming a c, Thoracic segments. b, Cephalic area. d, Rudimentary abdomen. e, Eyes.)

![Fig. 2.—The same; under size.](image2)

(a, a, Ovigerous legs.)

As examples of this class exhibiting extremes of variation in the development and reduction of the appendages may be cited *Decapoda*, which has the full complement of eight pairs of appendages, and the female of *Pycnogonum littorale*, in which all the appendages are aborted save four pairs of ambulatory limbs.

All the principal organs of the body are concentrated in that part which bears the appendages. The generative glands are lodged on each side, sending prolongations into the appendages, and their ducts open upon the second segments of more or fewer of them. The alimentary canal, beginning with the mouth at the extremity of the proboscis and terminating with the anus at the extremity of the tail-like opisthosoma, also sends long saccular prolongations into the limbs. Food is imbued by means of the suctorial pharynx lodged in the proboscis, the sucking action being effected by means of muscles radiating from the wall of the pharynx to that of the inner surface of the exoskeleton of the proboscis. The circulatory system, which has been observed, consists of a heart formed of about three chambers communicating with each other. In each chamber there is a pair of orifices for the entry of the blood; and the fluid is expelled through an orifice at the anterior extremity of the first chamber. No organs of respiration are known, the integument being the medium for the oxygenation of the blood. The sexes are distinct, but commonly there is little external difference between the males and the females. Sometimes the female is considerably the larger of the two; and frequently the ovigerous legs are less well developed than in the male. Sometimes indeed these limbs are entirely wanting in the female, whereas this is never the case in the male. Finally, in the females the generative orifices are much more conspicuous than in the males, and the fourth joint of the legs is often swollen. The invariable presence of the ovigerous appendages in the males is correlated with the habit practised by this sex of carrying the fecondated eggs. The eggs are usually aggregated in two spherical masses round the middle of each of the ovigerous legs; sometimes, however, there are two such masses on
PYCNOSTYLE—PYGMY

Galatea into the story. Pygmalion is also the name given in Virgil (Aenid, i. 347) to a king of Tyre, who murdered Schedias, the husband of his sister Dido.

PYGMALION, or Pygmy (Gr. πυγμάκος, from πυγμή, a Greek measure of length corresponding to "the distance between the elbow and knuckles" of a man of average size), a term for a diminutive human being. We owe the word to Homer, who in the Iliad (iii. 6) uses it to describe a race of tiny folk dwelling in a far southern land, whither the cranes fly when inclement winters and piercing frosts visit the northern shores. Fierce battles were often mentioned by later writers as occurring between the pygmies and cranes, and were even represented on their vases. On these the pygmies were depicted as dwarfs with large heads, negro features, close, curly hair, and sometimes armed with lances. Aristotle firmly believed in the existence of these pygmies, whom he characterized as a race of men of small stature inhabiting the marshes of upper Egypt towards the sources of the Nile. That their existence was a matter of common knowledge and speculation is indicated by the fact that Philostratus describes the sleeping Hercules beset by swarms of pygmies. Herodotus (ii. 32), relying apparently on authentic information, describes graphically how a party of five Nasamonienses, while journeying through the African desert, came at last to a plain where fruit-trees grew. While gathering the fruit they were seized by some dwarfish men of strange speech, who led them across forest marshes to a town, where dwelt people of a similar appearance, and near which a great river flowed from west to east containing crocodiles. This river was probably the Niger, and the people referred to were no doubt the ancestors of the existing pygmies of equatorial Africa. Representations of these pygmies have been found sculptured on the tombs at Sakkarah, which are referred to the Vth Dynasty of Egypt, 3106 B.C. The pygmies depicted in bas-relief on these tombs faithfully reproduce the racial characteristics of the present race of pygmies inhabiting the Ituri and Semiliki forests. They no doubt served in the household of the Egyptian kings, and figure both in Egyptian and Roman triumphs.

Various writers have localized pygmies in different portions of the earth's surface. Pliny makes mention of dwarfed races in both Asia and Africa. Reference is made to the Catizl dwarfs in Thrace, and to a similar race dwelling in Caria. Cesias, a century after Herodotus, wrote of a race of pygmies in the heart of India, describing them as black and ugly, and only two Pygmai in height. The Chinese author, Chao Fu-Kua, in the beginning of the 19th century, described a tribe of black pygmies dwelling in the Philippine Islands; in the depth of the valleys there lived, he said, a tribe of men called Hai-tan, small in size, with round yellow eyes, curly hair, and with the teeth showing through their lips. These were no doubt the ancestors of the present Aetas. Relics of a pygmy race are supposed to exist now in Sicily and Sardinia, i.e. along the high road between Pleistocene Africa and Europe. Near Schaffhausen, Dr. Kollman found skeletal remains of small human beings, which have been regarded by some authorities as belonging to the European pygmies of the Neolithic period. Some anthropologists have supposed the pygmies—indeed, in spite of the absence of definite data in support of such a view—believe that a dwarf negro race at one time existed in northern Europe, and may have given rise to the traditional tales of elves, goblins, gnomes and fairies.

At the present time the existing pygmy races may be subdivided into two main groups or sub-races: (a) the African pygmies (Negritoes), (b) the Asiatic pygmies (Negritos).

a. The African pygmies are dispersed over a large zone extending right across equatorial Africa, from Uganda to the Gaboon, the width of this zone being about six degrees, i.e. three degrees north and three degrees south of the equator. In Uganda they are now principally confined to a belt of forest lying to the east and west of the Semiliki River, though many centuries ago these forest dwarfs must have been the principal inhabitants of the whole of the Uganda Protectorate. They are much more abundant in the forests of the Belgian Congo, being found as far south as the range of the Angola, and to the north and north-west as far as the Bahir-el-Ghazal and the German Cameroons. They are also found in the interior of the French Congo and in the Gaboon. They comprise the Akkai...
the pygmies as a retrograde and degenerative type of the negro race and therefore of comparatively recent growth. Though the balance of evidence seems in favour of the former hypothesis, the question must still be regarded as sub judice. The first hypothesis would certainly go far to explain the present distribution of the pygmy races. If we regard, as many authorities do, the Indo-African continent, submerged in comparatively recent geological times by the waters of the Indian Ocean, as being the original home of primitive man, then it is easy to understand how he migrated from the subsiding Indo-African continent westward into the heart of Africa, and eastward to the Malay Peninsula by way of the Eastern Archipelago, at that time forming part of the mainland. Those members of the primitive race who migrated westward are supposed to have spread over the larger portion of the continent of Africa. They appear to have divided off into two main branches, the Negrillo pygmies of central Africa and the Bushmen of the southern portion of the continent.

These two sub-races appear to have been the aboriginal inhabitants of the country, though their direct descendants have now been driven into the stations by the more powerful Bantu races which sprang from the parent stem at a later date. A. H. Keane, who considers the recently extinct Kalang pygmies as the aborigines of Java, thinks it probable that this island was the first region reached by primitive man and his Miocene precursor during the eastward migration from the subsiding Indo-African continent.

General Characters of the Pygmy Races.—As regards stature, the smallest are the African Negrillos, their average height being 1'-38 m. (4 ft.). One of the six Mambute Negrillos brought to England by C. E. B. Morris measured just over 3 ft. Individuals not exceeding 3 ft. are met with, though the midgets of one or two pygmai in height, whose existence is indicated in the early Greek writings, must be relegated to the realm of mythology. The African pygmy is 4'-7 m., while the average height of the Sakal and Andamanese is 5'-7 m. in the Negritos.

The present writer estimated the weight of six adult Mambute pygmies (four males and two females) from the Ituri forest, and found that the average weight was seventy-seven pounds. Two of these, one man and one woman, each weighed forty-five pounds. All the pure pygmy tribes—whether Negrillos or Negritos—in addition to their small size have certain well-marked characters in common. The most notable of these are crisp, closely-curlied hair, flattened nose, broad at the base with a root and exorgerve development of the alae nasi, long upper lip with the mucous membrane moderately exorgerved, large ape-like nostrils, projecting chin, pronounced progynothyn, abundant fine woolly hair, long and slightly curved nails, unusually long arms and short legs, and a general simian appearance.

The colour of the skin shows considerable variation. The purest blooded African Akkas are of a peculiar dirty reddish-yellow colour, the Mambute and Mouton pygmies have a skin of a dark chocolate-brown hue, while that of the Oceanic Negritos is of a dark brown or blackish colour, differing little from that of the surrounding Papuans and Melanesians. The eyes of the pygmies are often large and into small eyes into which they pil their gazing.

The abdomen is protuberant in the case of the African pygmies, but not so in the case of the Oceanic Negritos. The mid-point of the body is above the umbilicus, instead of being below as in the case of Europeans. The pygmies are inclined to have a skin of a dark chocolate-brown hue, while that of the Oceanic Negritos is of a dark brown or blackish colour, differing little from that of the surrounding Papuans and Melanesians. The eyes of the pygmies are often large and into small eyes into which they pil their gazing.

The clothing is chiefly conspicuous by its absence. The African pygmies go about, for the most part, quite naked, except for the occasional presence of a small covering over the pudenda, the men wear no clothing whatever, the women for two or three bunches of green leaves, which they renew daily. The resemblance to the traditional fig-leaf covering is obvious. The Andamanese wear practically no clothing. The Karons of New Guinea wear a large strip of skin hanging from a string round the loins. The Negrillos seldom, if ever, wear clothing. They are fond of beads and other articles of adornment; the upper lips are often pierced with holes, through which quills are thrust. They cut their short curly hair into all sorts of fantastic patterns, and often twist some of it into plait through the in the town.

Pygmy dwellings are extremely primitive structures. In Africa they are simply arbours constructed of bent interlaced branches and plantain leaves, about 7 ft. in diameter and 4 ft. high, with a

(Tiky-Tiky) of the upper Nile, and of the Niam-Niam country; the Wombuti (Mbuti, Mambute, Bambute) of the great Ituri forest, and the Batwa (Watwa) living to the south of the great curve of the Congo river. In the vast forest tract lying between the region of the upper Nile and the Ituri forest there are other semi-nomadic tribes of pygmies differing in no essential particular from these, and severally known as Affi (of the Momul country); Obongo, Wosuga, Akua, Acharo (of the French Congo), Ba-Bengaye (of the Belgian Congo), and the isolated Negritos of the Philippines and the Mentawai Islands. It is only in the form of a glossary that they have been noted outside these limits, e.g. in the basin of the upper Kasai, as far east as Lake Tanganyika, and even to the north of Lakes Stefania and Rudolf in British East Africa. There has been much confusion of the name of the Negritos with the neighbouring Bantu peoples, e.g. Adumas, &c.

b. The distribution of the Asiatic pygmies is mainly oceanic. The following are the three principal tribes. (1) The Atias (Philippine) and the Mbuti of the Ituri forest. Among the former, the word hitam, meaning black. These little folk dwell in small groups in the interior of Luzon Island, and are to be met with also in the islands of Mindoro, Panay and Negros, and in the north-east of Mindanao. The number of the group is estimated at 20,000. (2) The Andamanese (Andaman Islands). These live in isolated groups of fifty to eighty persons. They appear to be dying out, and in 1891 numbered less than 4000. The term Mincopis has sometimes been used as a synonym of Negritos, but it is now used to denote the inhabitants of the Malay Peninsula. Some of these Malay Negritos are also known as Somangs, Menik, Sen-oi and Jembe. They live for the most part in small groups from two to three families. In the Ulu-Papung district alone the population is estimated at 2000, but there is no accurate statement of the forest population, however, with the surrounding Malay population. Thus the Mintra and Jakhuns are Sakai-Malay cross-breeds. In Malacca the Fangyans of Kelantan and Petani and the neighbouring Tumins are typical Negritos, while the Negritos of the Brook. Some anthropologists believe that the Sakas of the islands on the north-east coast of Sumatra are also derived from Negritos.

A group of Negritos—the Karonks—has also been discovered in the north-west coast of New Guinea. Here also there are Negrito-Papuan cross-breeds. There is much diversity of opinion as to whether the recently extinct Kalang of Java—in some respects the most ape-like of all human beings—did or did not have a distinct Negrito stock, or whether they derived from a race of more primitive type, as has been shown by the remains of the species presented by the native forest Pygmies are as diverse as could be expected from the different conditions under which they have lived. The pygmy tribes are divided into several groups, each with its own distinct racial characteristics, yet all are united by certain common features of body and mind. The eyes are usually large and round, the nose flat and broad, and the skin thick and dark. The hair is usually short, coarse, and black, and is sometimes worn long, especially in the case of the women.

A passing reference may here be made to the Bushmen of South Africa, whose average height (4 ft. 8 in.) approximates to that of the true pygmies. Some authorities believe that there is a distinct ethnological division between these two groups, although in many respects the forest pygmies seem more closely allied to the West African Bantu negroes than to the Bushmen-Hottentot group. Professor Elliott Smith is, indeed, of opinion that the Bushmen and African negroes are a distinct race, and that there is a direct connection between the pygmy and the Bushmen. Schweinfurth, who rediscovered the Akka pygmies of equatorial Africa, believed that they and the Bushmen of South Africa were the remnants of the aboriginal population of the continent, now reduced to a small number.

Consideration of the distribution and general characteristics of the existing pygmy races—Negrillos and Negritos—has induced many anthropologists to conclude that we are dealing with the but little modified descendants of an extremely ancient race—the ancestors possibly of all the negro tribes. Sir W. H. Flower himself, as far back as 1880, stated that he was inclined to regard the Negritos as representing an infantile, undeveloped, or primitive form of the type from which the African negroes on the one hand, and the Asiatic Melanesians on the other, with all their various modifications, may have sprung. If this be the case, it seems probable that the members of the African pygmy races are the only existing link between the two races, and that they are the closest resemblance of the primitive man.

On the other hand, there are those who regard

In the Times of June 3, 1910, was reported a discovery, made by an expedition organized by the British Ornithologists' Union, of a tribe of pygmy people (probably Negritos) in the great snow mountains of Dutch New Guinea, at an altitude of about 2000 ft. The average height of these pygmies is about 4 ft. 3 in.
small hole near the bottom, through which the pygmy crawls on all fours. Ten or twelve of these arbours constitute a village. These arbours are only temporary habitations, as the pygmies are always moving on to different portions of the forest in pursuit of game. Among the Semang, the villages consist of a semicircular enclosure. The dwellings of the Malay Semangs are mere lean-to's, constructed of matted palm-leaves, while the Karons of New Guinea live in wretched hovels of foliage and branches, and in some districts have no habitations whatever. They eat the vegetables raw, while the meat is broiled in the ashes of the fire until quite dry. Their utensils consist solely of a few clay pots and a wooden bedstead. Thieves is not one of their canibalism among the pygmy races. The six Mambute pygmies brought to England in 1906 soon became acclimatized. They took their European clothes and diet with enthusiasm. At the expiry of eighteen months they were able to live on a British staple diet. They have each gained on an average 9 lb in weight.

They are most daring hunters, and marvellously skilful archers. Though of small size they are well made and agile, and are able to dart in and out with the greatest of ease amongst the tall tangled vegetation. The pygmy, as the blacks of the Congo, successfully attack elephants, shooting them with their tiny poisoned arrows. The poison is obtained from the juice of certain plants, and also from decaying animal matter derived from the bodies of venomous ants. The Andaman pygmies live exclusively by hunting and fishing. The African pygmies marry at a very early age, often when only nine years old. Marriage is simply a question of the purchase of the girl from her father; the purchase-price being from ten to fifteen arrows, occasionally supplemented, in the case of a desirable wife, by one or two spears or some tobacco. A man may have as many wives as he can afford to buy. A mother gives birth to her offspring in the forest, severing the navel-cord with her teeth, and if the baby survives the first week in the family, the families are usually small, rarely exceeding three in number. There is great rejoicing when a boy is born, while the unlucky girl baby is beaten by her father with plantain leaves. The boys are often circumcised. The Africans hold affection between the husband and the wife and between the parents and the children. The duration of life is short in the equatorial forests, death usually taking place before the age of forty. The dead are buried in graves, the chief’s wife being sometimes killed and buried along with him. The African pygmies have little if any belief in life after death. They say death is the end of everything. They have a vague belief in “Oudah,” a sort of pygmy devil, who is responsible for sudden death and such-like calamities. There is no trace of spirit or animal worship among the Andaman pygmies. Jap is described as a sort of god.”“Puluga”—an invisible being who lives in a large stone house in the sky, and who made all things. They also believe in an evil one, to whom they attribute sickness and death. The Andaman chief, who is a simple cluster round a skilful hunter. In the case of the Mambute pygmies, a chief is succeeded, not by his son, but by his best friend. There are no governmental laws. Murder in the Ituri forest is punished by the next-of-kin lying in wait for the culprit and killing him.

The Negritos are fond of music and have numerous folk-songs. They also swang on stringed bows, and beat drums made of hollowed-out tree trunks covered over at the ends with animal skins. They are also excellent dancers, keeping a perfect time to the beating of the drums their bodies going through the most extraordinary contortions. They all dance together in a long line, which twists about like a snake.

genetically, the forest dwellers have some idea of drawing, each arrow shaft having its distinctive carving. The Andamanese display a considerable degree of intelligence. The Karons of New Guinea, on the other hand, seem to be of a low type of intelligence. The Negritos have acquired a certain reputation among the neighbouring tribes for their knowledge of poisons and their antidotes. Their treatment of all pains and inflammations consists in linear scarification of the skin of the affected part. They invariably use sharp thorny sticks for this purpose. Close observation has convinced the present writer that the African pygmies are endowed with a high degree of intelligence. Sir Harry Johnston believes them to be the intellectual superiors of a great many of the negroes. They excel in picking up information and languages, and surprising readiness in grasping the salient points of a subject. They are wonderful mimics and have a marked sense of humour, making witty remarks which set the others off into peals of laughter. They are as a rule cheerful and cheerful disposition, will sometimes fall into sudden fits of ill temper and as quickly recover their good humour. They are cleanly in their habits, have a natural sense of modesty and refinement, and punctiliously observe the ordinary décencies of life.

The pygmies of the Malay Peninsula have a perfectly distinct language of their own. A glossary and grammar with phonetic rules of the Sen-oi dialect has been published, showing no connexion with any other known language.

The African pygmies, for the most part, speak a more or less corrupt form of the language of the adjacent negro tribes, e.g. Mbo. Mier. They have some words, however, peculiar to themselves, which may be the fragments of their own original language.

PYLE, HOWARD (1853-1943), American artist and writer, was born at Wilmington, Delaware, on the 5th of March 1853. He was a pupil of the Art Students’ League, New York, and first attracted attention by his life drawings after the manner of Albrecht Dürer. His brilliant work as an illustrator made him one of the foremost of American artists, his drawings to illustrate American colonial life, particularly in New England and New Amsterdam, being especially noteworthy; and he published a number of books of fiction, written and illustrated by himself. He also became prominent in decorative painting, his works including “The Battle of Nashville” for the capitol at St Paul, Minnesota, and “The Landing of Carteret” for the Essex county court house, Newark, New Jersey. At his home in Wilmington, Delaware, he established a school of art, instruction being gratuitous, and many successful American illustrators were educated there. In 1907 Howard Pyle was elected a member of the National Academy of Design.

PYLOME, in Zoology, the name given to the principal opening (or openings) of the shell (theca, testa) of such Protozoa as possess one. (See FORAMINIFERA, RADIOLARIA.)

PYLOS (mod. Navarino), in ancient geography a town and bay on the west coast of Messenia, noted chiefly for the part it played in the Peloponnesean War. The bay, roughly semi-circular in shape, is protected by the island of Sphacteria (mod. Spagna), over 2½ m. long from N. to S., and is entered by two channels, that on the S., some 1,400 yds. wide, and that on the N., 220 yds. wide and now almost silted up. To the north lies an extensive shallow basin, called the lagoon of Osman Agra, originally part of the great harbour but now cut off from it by a narrow sand-bank. North of Sphacteria is the rocky headland of Pylos or Coryphasium, called in modern times Palaeo-Navarino or Palaeokastro, from the Venetian ruins on its summit. Originally an island, this headland was in classical times, as now, connected by a narrow bar with the lower promontory of Hagios Nikolaos on the north; it is now united to the mainland also by the sandbar already mentioned. Most scholars, ancient and modern, have identified this with the Homeric Pylos, the home of Neleus and Nestor, and a cave on the north slope of Coryphasium is pointed out as that in which Hermes hid the stolen cattle of Apollo. But this view presents considerable difficulties, and Strabo (viii. 348 sqq.) argued that the Pylos of Nestor must be the place of that name in Triphylia. After the Dorian migration Pylos declined, and it is referred to by Thucydides (iv. 3) as a deserted headland in 425 B.C. In May of that year, the seventh of the Peloponnesian War, the Athenians sent an expedition to Sicily under command of Euryomen and Sophocles. With them was the general, Demostenes, who landed at Coryphasium with a body of Athenian troops and hastily fortified it. The Spartans, who were then invading Attica, withdrew their forces from the gullies of the Pylos to Sphacteria. The beaches were re-occupied, and the Athenians were enabled by the arrival and victory of their fleet to blockade on the island of Sphacteria a body of 420 Spartiates with their attendant helots. A truce was concluded, but peace negotiations were defeated by Cleon (q.v.), who was himself appointed to conduct operations with Demostenes. A large body of light troops was landed and drove the Spartans from their encampment by a well in the middle of the island to its northern extremity. Their heroic resistance was overcome by a rear attack directed by a Messenian, who led a body of men by a difficult path along the cliffs on the east, and the 202 Spartan survivors laid down their arms 72 days after the beginning of the blockade. Their surrender made a deep impression on the whole Greek world, which had learned to regard
a Spartan surrender as inconceivable, and to Sparta their loss was so serious that the Athenian might have concluded the war on very favourable terms had the enterprise succeeded. Though Pylos should have been ceded to Sparta under the terms of Nicias (421 B.C.) it was retained by the Athenians until the Spartans recaptured it early in 409 B.C. (Diodorus xiii. 64).

In the middle ages the name Pylos was replaced by that of Avarino (Ἀβαρίνος) or Navarino, derived from a body of Avars who settled there; the current derivation from the Navarrese Company, who entered Greece in 1381 and built a castle at this spot, cannot now be maintained (Eng. Hist. Review, xx. 307, xxi. 106; Herathenna, xxi. 430 sqq.). From 1498 to 1821 Navarino was in the hands of the Turks, save at two periods when it was held by the Venetians, who named it Zonklo. In 1821 the Greeks captured the town, situated near the southern extremity of the bay, but in 1825 they had to retire before Ibrahim Pasha. On the 20th of October 1827, however, his fleet of 82 vessels was annihilated in the Bay of Navarino by 26 British, French and Russian ships under Admiral Codrington (see NAVARINO, THE BATTLE OF).

See W. M. Leake, Travels in the Morea, i. 398 sqq. (London, 1830), and Peloponnesius, 190 sqq. (London, 1840); E. Curtius, Peloponnesus: Geschichte des Peloponnes (Berlin, 1872); J. H. Rawlinson, History of Greece, ii. 175 sqq. (Leipzig, 1869); Pausanius iv. 36, and the commentary in J. G. Frazer, Pausanius's Description of Greece, iii. 456 sqq., v. 608 sqq. (London, 1898); W. G. Clark, Peloponnesus, 214 sqq. (London, 1899); J. H. Rawlinson, the History of Greece, vii. 57, viii. 165 sqq. (Eng. trans., Basel, 1857); G. Grote, History of Greece, pt. ii. ch. 52; G. Busolt, Griechische Geschichte, iii. 1086 sqq.; F. M. Cornford, Thucydides mythistorius, 82 sqq. (London, 1907). The operations of Pylos were first described in the works of Roger ofcover, but they are discussed on the basis of personal observation by Dr. C. B. Grundy (Journal of Hellenic Studies, xvi. 1 sqq.; Classical Review, x. 371 sqq., xi. 155 sqq., 448; J.H.S., xvi. 332 sqq.) and Professor R. M. Burrows (J.H.S., xii. 55 sqq., xii. 1 sqq., J.H.S., xvii. 147 sqq., 345 sqq., C.R., xiv. 189 sqq.). Those differing in many points, they agree in thinking (1) that the island of Sphacteria is the ancient Sphaica, Palaeokastro the ancient Coryphum or Pylos; (2) that in 425 B.C. the lagoon of Osman Aga was navigable and communicated by a navigable channel with the Bay of Navarino; (3) that Thucyllides, if the MS. reading is correct, underestimates the length of the island, which he gives as 15 stades instead of 24 (nearly 3 m.), and also the breadth of the southern channel between it and the mainland (Cf. J.H.S., xx. 14 sqq., xxvii. 274 sqq., and Frazer's summary (op. cit. v. 608 sqq.). (M. N. T.)

PYM, JOHN (1584-1643), English statesman, was the son and heir of Alexander Pym, of Brymøre, Somersetshire, a member of an ancient family which had held this seat in direct male descent from the time of Henry II. He matriculated as a commoner at Broadgates Hall (now Lady Margaret College) Oxford, in 1599, and entered the Middle Temple in 1602. He possessed a sound knowledge of the law, and became receiver-general of the king's revenue for Wilts., thus gaining a valuable insight into business and finance. He was returned to parliament as member for Calne in 1614 and again in 1621. He at once became conspicuous in the struggle between Crown and parliament. To the committee appointed to consider the state of religion he made his first great speech on the 28th of November 1621. He held fast to the Elizabethan principle that the Roman Catholics should be subjected to disabilities, not because of their religion, but because of their politics. He, therefore, moved that a special commission for the suppression of recusancy should be appointed, and that an association, after the model of those formed under Elizabeth, should be entered into for defence of the king's person and for the execution of the laws concerning religion. Pym supported Sir Edward Coke in the remonstrance on the prevailing discontents, and was a chief promoter of the petition which incurred James's violent displeasure, and of the Commons' answer defending their privileges, which was afterwards torn to pieces by the words of the king's own hand. On the dissolution of parliament which followed, Pym with other "ill-tempered spirits," was arrested in January 1622, and was confined first to his house in London, and then to Brymøre. He associated himself with the party of Francis, 4th earl of Bedford, was returned for Taunton in 1624, and represented this borough in all the ensuing parliaments. He supported Eliot in urging war against Spain for the defence of Protestantism and the Palatinate, and showed throughout his career, as far as his attention was ever directed to foreign policy, a strong inclination in favour of France.

In the parliament of 1625 he continued his campaign against the Roman Catholics, and drew up with Sir Edwin Sandys the articles against them, and the petition to the king for the direct execution of the penal laws. In the parliament of 1626 he was the chief mover, in April, in the prosecution of Richard Montague, who had advocated Romish doctrines. On the 8th of May he was manager of Buckingham's impeachment, when it was his special duty to press articles ix., x., xi., relating to the improper distribution of rewards and honours. In the third parliament of Charles I., in 1628, Pym overruled Eliot in deciding that Buckingham's impeachment should now be subordinated to the struggle on general grievances. He zealously pushed on the Petition of Right, resisting on the 20th of May the clause added by the Lords to safeguard the king's "sovereign power," declaring that "he knew not what it was." On the 9th of June he carried up to the Lords the impeachment of Roger Manwaring, and delivered a famous speech in which he expounded the fundamental principles which guided his policy.

"Histories," he said, "are full of the calamities of whole states and nations ... when one part seeks to uphold the old form of government, while the other seeks to introduce a new ... But it is equally true that time must needs bring about some alterations ... Those things only are eternal which are constant and uniform. Therefore it is observed by the best writers on the subject, that that which is most durable and perpetual which have often reformed and recompensed themselves according to their first institution and ordinance."

On the 11th of June he joined in the attack upon Buckingham, whom he regarded as the "cause of all these grievances." On the 27th of January 1629 he was reporter of the committee on religion, and declared that conviction was dependent upon parliament. He again, in February 1629, differed from Eliot, who treated the dispute about tonnage and poundage as a point of privilege, declaring that "the liberties of this house are inferior to the liberties of the kingdom," and desiring to deal with it on higher ground as a breach of law and the constitution. He took no part in the subsequent disturbance in the house, and his name is not mentioned as actively resisting Charles's arbitrary government during the eleven years which followed the dissolution. At this period the state of public affairs may well have appalled the most hopeful and the most patriotic, but there seems no sufficient authority for the belief that Pym, with Hampden and Cromwell, actually embarked for New England and were among the first voluntary settlers from the government. An allusion, however, to a similar move, was formed by some very considerable personages," "diverted by a miraculous providence," is made in a sermon by Thomas Cave in 1642. Pym himself was directly interested in the colonies, being patentee of Connecticut and Providence, and of the latter company also treasurer, and there can be little doubt that like other leaders of the opposition during this period, the King regarded America as a possible refuge.

On the assembly of the Short Parliament on the 13th of April 1640, Pym was the acknowledged leader. "Whilst men gazed upon each other," says Clarendon (Hist. ii. 68), "looking who should begin (much the greater part having never before sat in parliament), Mr Pym, a man of good reputation ... who had been as long in these assemblies as any man there living, broke the ice." On the 17th of April he made a great speech of nearly two hours, in which he enumerated the national grievances, deplored almost in the words of Bacon "the interruption of that sweet communion which ought to be betwixt the king and his people in matters of grant and supply," pointed out the practical injury inflicted on commerce and every sort of enterprise including colonial expansion by illegal and arbitrary taxation, and concluded by asking the Lords to join in finding out causes and remedies. His words made a deep impression. On the 27th of April he resisted the grant of supply, and when the Lords passed a resolution that supply should precede the
discussion of grievances, Pym, as manager of the Commons, on the 1st of May, read them a severe lecture on the breach of privilege they had committed. Finally, on the 4th, it was resolved that Pym should next day petition the king to make terms with the Scots, to avoid which Charles summarily dissolved the parliament.

All the energies of Pym were now concentrated on obliging Charles to summon another parliament. He was the author of the petition of the twelve peers to the king for redress of grievances, and for calling a new parliament, by the wide distribution of which an appeal was made to the nation, and he was the promoter of the petition signed by 10,000 citizens of London. In company with Hampden he rode through the provinces, rousing and organizing public opinion. Meanwhile Charles's attempt to implicate Pym in treasonable communications with the Scots, though there is little doubt that they existed, met with complete failure. Thus, when the king was forced to call the Long Parliament on the 3rd of November, Pym was its acknowledged author and leader. His great work was now, as he conceived it, to save the national liberties and the national religion. Clarendon (Hist. iii. 2) records some "sharp discourse" of Pym with himself at this time, "that they had now an opportunity to make their country happy by removing all grievances and pulling up the causes by the roots, if all men would do their duties." He had seen Vane's notes of Strafford's speeches at the council when he had advised the subduing of "this kingdom" by the Irish army, and on the 7th of November, after declaring to the house the dangerous designs then on foot, Pym moved for a sub-committee to examine into Strafford's conduct in Ireland. The latter's sudden arrival at London on the 9th with the intention of instantly impeaching the popular leaders of treason was met by Pym with corresponding quickness and resolution. On the 11th, after a debate of four hours in the Commons, by his directions with locked doors, he carried up Strafford's impeachment to the Lords, and by this great stroke rendered him at once powerless.

On the 16th of December he moved the impeachment of Laud, whom he joined with Strafford as conspiring to subvert the government of the kingdom, and carried up the articles to the Lords on the 26th of February 1641. He was the chief promoter of the case against Strafford, while the attempts of the queen to gain him over were without result, and on the 28th of January 1641 he brought up to the Lords the list of charges. On the 23d of March he opened the case, when he argued that to attempt to subvert the laws of the kingdom was high treason, and delivered a violent denunciation against the fallen minister, attributing to him "systematic cruelty, avarice and corruption. He soon afterwards heard of the army plot, and the necessity of destroying Strafford became more apparent. He now disclosed Vane's notes. To the attender, which was at this stage resolved upon, he was opposed (since he clung to the more judicial procedure by impeachment), but when overruled he supported it, at the same time procuring that the legal arguments should not be interrupted. He delivered his final speech on the 13th of April, a great oratorical performance, when he again appealed to the Elizabethan political faith and to that of Bacon, who had so severely censured any action which divided the king from the nation. The man who violated this union was guilty of the blackest treason. "Shall it be treason," he asked, "to embrace the King's coin though but a piece... of sixpence... and not to embrace the spirits of his subjects; to set a stamp and character of servitude upon them?" Towards the end of his tremendous indictment of Strafford, Pym broke down, fumbled among his papers, and lost the thread of his argument. But his temporary failure did not diminish the force and effect of his words, all the more impressive because actually spoken in the presence of the sovereign. "I believe," wrote Baillie (Letters, i. 348) "the king never heard a lecture of so free language against that his idolized prerogative."

Attempts were now once more made to gain over Pym to the administration. He had two interviews with the king, but without result, and Charles again determined to resort to force. On the 2nd of May he "endeavoured to get possession of the Tower. On the 3rd the Protestation, on Pym's motion, was taken by the Commons within closed doors, and afterwards circulated in the country, and on the 5th Pym disclosed the army plot. These incidents decided the struggle and Strafford's fate. The Lords immediately passed the attainer, together with the bill for making parliaments indissoluble without their own consent. Soon afterwards were swept away those institutions of Tudor growth which had become the chief instruments of oppression, the council of the North, the court of high commission, and the star chamber, while the Crown abandoned the claim to levy customs without consent of parliament. Meanwhile Pym had also taken the lead in the religious controversy. During the dispute between the two houses on this question on the 9th and 9th of February 1641, while supporting the Lords in the passage of the third petition for the restitution of the bishops, he had declared his opinion that "it was not the intention of the House to abolish episcopacy or the Book of Common Prayer, but to reform both wherein offence was given to the people." This, no doubt, expressed his real intentions and policy. When, however, it became clear that the bishops were merely the nominees of the king to carry out "innovations in religion" and preach arbitrary government, Pym was easily persuaded to support their abolition, and voted in opposition to the moderate party for the Root and Branch Bill of May 1641, and again for taking away their votes in October. But in his "Vindication," published in March 1643, he especially states that his action with regard to the bishops in "no way concluded me guilty of revolt from the orthodox doctrine of the Church of England."

The first act in the great political struggle had ended in the complete triumph of Pym. His chief care now was to defend the parliament from violence, since this was the only method of retaliation left as the king's disposal. Through the medium of the countess of Carlisle, Charles's plans were regularly disclosed to Pym. In June he heard of the second army plot, and on the 22nd he carried up the ten propositions to the Lords, requesting their concurrence in effecting the disbandment of the armies and the removal of evil counsellors. After Charles's departure for Scotland, Pym served on the committee for defence, appointed on the 14th of August, and was chairman of the committee which sat during the recess from the 9th of September to the 20th of October to watch the progress of affairs and communicate with Scotland. On the latter day letters arrived from Hampden, who had accompanied Charles, with news of the "incident," and immediate measures were taken to guard the parliament, by bringing up the train-bands. On the 30th Pym revealed his knowledge of the second army plot. On the 1st of November came news of the Ulster insurrection, which created a serious difficulty for the parliament, when it was finally declared, at Pym's instance, that if the king did not change his advisers parliament would provide for the needs of Ireland independently. On the 22nd of November Pym made a great speech on the Grand Remonstrance, of which he was the chief promoter, when he referred to plots "very near the king, all driven home to the court and popish party."

Charles returned on the 25th. He immediately substituted a force commanded by Dorset for the guard already placed at Westminster, but was compelled to withdraw it, and on Pym's motion the house appointed its own watch. Everything now pointed to the advent of a frightful catastrophe. Charles appointed Lumsford to the Tower, rejected the Grand Remonstrance and the Impressment Bill, and began to assemble an armed force. In consequence Pym urged, but unsuccessfully, on the 26th of December the summoning of the train-bands to guard the parliament, and moved the impeachment of the bishops, who had declared the proceedings of the parliament to be sinful and illegal. At the critical moment, however, Charles wavered. He renewed his offer to Pym of the exchequer on the 1st of January 1642, and this meeting with a refusal, or again drawing back himself, determined on the impeachment of the five members on the 3rd of January. The latter had been
forewarned of the king's plans, and when on the 5th he entered the House of Commons with an armed band to seize them, they had removed themselves in safety (see Lenthal, William). Charles's first look on entering was for his great opponent, and he was greatly disconcerted at not finding him in his usual place. To his question "Is Mr Pym here?" there was no answer, and nothing remained but to retreat with his mission completely unachieved.

The second act in the great national drama had thus, as the first, ended in a victory for Pym. On the 11th, with the other members, he was escorted in triumph back to Westminster, and while the other four stood uncovered, Pym returned thanks from his place to the citizens. On the 27th of January he delivered a great speech to the Lords on the perils attending the kingdom, and referring to their hesitation on the subject of the militia, declared that he should be sorry that history should have to relate that the House of Peers had had no part in the preservation of the state in the present extremity of danger. The Commons ordered his speech to be printed, and it provided the chief material for the paper war between Charles and the parliament which now followed. Still endeavouing to avoid a complete breach of constitutional forms, Pym caused to be added to the resolution of the Commons on the 20th of May 1642, which declared that "the king intends to make war against the parliament," the words "seduced by wicked counsel."

When war broke out, Pym remained at headquarters in control of the parliament and executive, and on the 4th of July was appointed to the committee of safety which directed the movements of the parliamentary forces. His attitude was firm but moderate. He opposed the attempt to prevent Colepepper giving the king's message to the house on the 27th of August. On the 20th of October, upon Charles refusing to accept the petition of the parliament and advancing towards London, Pym proposed the parliamentary covenant, and that those who refused it should be "cast out of the House." He succeeded in overcoming the opposition in the city to the heavy taxation now imposed. On the 10th of November, after Edgehill, he spoke in support of the negotiations for peace, at the same time warning the citizens that "to have printed liberties and not to have liberty in truth and reality is but to mock the kingdom." In February 1643 he still showed an inclination for peace, and during the negotiation of the treaty at Oxford supported the disbandment of the armies. When it was evident that peace would not be secured, he proposed in order to carry on the war an excise, hitherto unknown in England, which met with the same violent hostility afterwards aroused by Walpole's scheme. In March he published a "Dissertation and Vindication" of his public conduct, in which he threw the whole blame of the appeal to arms on the opposite party, and expressed his fidelity to the Church and constitution. In May he entered, together with the other leaders, into needless negotiations with the queen, and on the 23rd he took up her impeachment to the Lords. In June he reported on Waller's plot, which exposed the insincerity of Charles's negotiations, and on the 26th of June wrote a "sharp letter" to Essex on his inaction. In July, after the defeat at Adwalton Moor, he prevented the house from again initiating negotiations for peace, which he declared "full of hazard and full of danger," and on the 3rd of August, after having visited Essex at Kingston, persuaded him to separate himself from the peace propositions of the Lords and to march to relieve Gloucester. He thus incurred the hatred of the peace party, and on the 9th of August a mob of women surrounded the house calling for its destruction, and were not dispersed without some bloodshed.

Pym had already, on the 3rd of January, proposed to the house an alliance with the Scots, and the Royalist victories now induced parliament to consent to what had before been rejected. The establishment of Presbyterianism was accepted by Pym as a disagreeable necessity, and he was one of the first to take the covenant on the 25th of September. This alliance, which was afterwards destined to have so decisive an influence on the military campaign, and was the first occasion on which the two nations had united in public action, closes Pym's great career. He was made master of the ordnance on the 8th of November, but died on the 8th of December at Derby House, where he resided. On the 17th of December he received a public funeral in Westminster Abbey, whence his body was ejected at the Restoration. A sum of £10,000 was voted by the parliament to pay Pym's debts and provide for his family. About 1614 Pym married Anne Hooke, or Hooker (d. 1620), by whom he had five children, including two sons, Alexander, who died unmarried, and Charles, who was created a baronet; this title, together with Pym's male line, became extinct in the person of Pym's grandson Charles in 1688, Brymore then passing to his sister Mary, wife of Sir Thomas Hales, Bart.

Pym had little of the Puritan in his character or demeanour. His good humour, humanity and cheerfulness in all circumstances, his pleasant countenance and sweet behaviour, are marked characteristics; the aspirations, however, on his morals, as well as the accusations of bribery, are completely unsubstantiated and discredited. His death came as an irreparable loss to the parliamentary cause. "Since Pym died," writes Bailleau (Letters, i, 216), "not a state head among them; many very good and able spirits, but not any so great and comprehensive a braine as to manage the multitude of weighty affairs as lyes on them." He was one of the greatest leaders that the House of Commons has produced, a most capable man of business, and indefatigable in assiduous attention to its details. He possessed great tact in influencing the conduct of the house and in removing personal jealousies on critical occasions, and he excelled as a party leader in choosing and directing the course of policy, and in keeping his followers united and organized in its prosecution, as well as in stimulating and guiding popular opinion outside in its support. The frequent appeals to the nation by protests, oaths of association and popular petitions, were a very striking feature in Pym's policy, one of the chief sources of his strength, and new in English history. We may indeed perhaps see in these and in the canvassing of constituencies conducted by Pym and Hampden the beginnings of party government. His eloquence lay rather in the clearness of his expression and in the depth and solidity of his ideas than in the more showy arts of oratory. Much of his success as a leader was the result of the confidence inspired by his high character, his well-tried courage and resolution at critical moments, his skill and vigilance in unmasking and frustrating the designs of the opposite faction. But Pym was not only great as a party leader; he had the real instinct of construction, the true test of the statesman. This construction, he believed, in the spirit of genuine conservatism, must always be progress along the lines of natural development, and not by the methods of revolutionary or extraneous innovation. It was Pym's chief charge against Charles, Stafford and Laud that they had arrested this progress, and were thus leading the nation to ruin and dissolution. Such was the theory and conviction, inherited from Bacon and passed on to Halifax and Burke, which underlay and inspired Pym's policy.

The article on Pym by S. R. Gardiner, in the Dict. Nat. Bldg., with its references to authorities, must be supplemented by J. Forster, A Short History of the English People, 1 (2nd ed., 1819), and by Hume, History of Great Britain, vol. ii (1767), and the more recent works of Lord Macaulay and other historians. Pym's life has also been written at length by J. Forster in Lardner's Cabinet Cyclopaedia, Eminent British Statesmen, vol. iii, and by Wood in Aik. donum, iii. 72, who adds a list of Pym's printed speeches. His character, drawn by Clarendon, Hist. iii. 30 and viii. 490, is inaccurate and obviously prejudiced. See also J. Forster's Grand Remonstrance, Arrest of the Five Members, Lives of Sir J. Eliot; Vernon's Notes of the Long Parliament; Wharton's Memorials; (ealing columns Collections; Trench, Thomas Tracts, 153 (10), 53 (8), 172 (14), 164 (3), 200 (13) (26) (37) (49) (65), 199 (24) (49), 78 (13); Somers Tracts iv. 217, 355, 461, 466, and death's Sermon by C. Fitzwilliam, 173 (22); 192; 397; 1602; and Commons Journals. There are a large number of references to Pym in Calendars of State Papers Dom. 1619–1643, and Colonial Series 1574–1660, and in the Hist. MSS. Comm. Series; but the supposed notebook of Pym mentioned in Eng. Hist. Rev., Jan. 1895, p. 105, has been shown by Gardiner to be that of another person (Eng. Hist. Rev., Jan. 1895, p. 105).
PYRAMID, the name for a class of buildings, first taken from a part of the structure, and mistakenly applied to the whole of it by the Greeks, which has now so far acquired a more definite meaning in its geometrical sense that it is desirable to employ it in that sense alone. A pyramid therefore should be understood as meaning a building bounded by a polygonal base and plane triangular sides which meet in an apex. Such a form of architecture is only known in Middle Egypt, and there only during the period from the IVth to the XIIth Dynasty (before 3000 B.C.)—having square bases and angles of about 50°. In other countries various modifications of the tumulus, barrow or burial-heap have arisen which have come near to this type; but these when formed of earth are usually circular, or if square have a flat top, and when built of stone are always in steps or terraces. The imitations of the true Egyptian pyramid at Thebes, Meroe and elsewhere are puny hybrids, being merely chambers with a pyramidal outside and porticos attached; and the structures found at Cenchreae, and the monument of Caius Sestius at Rome, are isolated and barren trials of a type which never could be revived: it had run its course in a country, and a civilization to which alone it was suitable.

The origin of the pyramid type has been entirely explained by the discovery of the various stages of development of the tomb. In prehistoric times a square chamber was sunk in the ground, the dead placed in it, and a roof of poles and brushwood overlaid with sand covered the top. The 1st Dynasty kings developed a wooden lining to the chamber; then a wooden chamber free-standing in the pit, with a beam roof, then a stairway at the side to descend; then a pile of earth held in by a dwarf wall over it. By the 11th Dynasty this dwarf wall had expanded into a solid mass of brickwork, about 280 by 150 ft. and 33 ft. high. This was the mastaba type of tomb, with a long sloping passage descending to the chamber far below it. This pile of brickwork was then copied in stone work early in the 11th Dynasty (Saqqara). It was then enlarged by repeated heights, and successive coats of masonry. And lastly a smooth casing was put over the whole, and the first pyramid appeared (Medum).

It is certain that the pyramids were each begun with a definite design for their size and arrangement; at least this is plainly seen in the two largest, where continuous accretion (such as Lepsius and his followers propound) would be most likely to be met with. On looking at any section of these buildings it will be seen how impossible it would have been for the passages to have belonged to a smaller structure (Pietre, 165). The supposition that the designs were enlarged so long as the builder's life permitted was drawn from the compound mastabas of Saqqara and Medum; these are, however, quite distinct architecturally from true pyramids, and appear to have been enlarged at long intervals, being elaborately finished with fine casing at the close of each addition.

Around many of the pyramids perilous walls may be seen, and it is probable that some enclosure originally existed around each of them. At the pyramids of Gizeh the temples attached to these mausolea may be still seen. As in the private tomb, the false door which represented the exit of the deceased person from this world, and towards which the offerings were made, was always on the west wall in the chamber, so the pyramid was placed on the west of the temple in which the deceased king was worshipped. The temple being entered from the east (as in the Jewish temples), the worshippers faced the west, looking towards the pyramid in which the king was buried. Priests of the various pyramids are continually mentioned during the old kingdom, and the religious endowments of many of the priesthoods of the early kings were revived under the Egyptian renaissance of the XXVIth Dynasty and continued during Ptolemaic times. A list of the hieroglyphic names of nineteen pyramids was composed in the Ptolemaic period (see Conybeare, Rev. Equ., 2nd year, 305-309), hence the Greek form pyramids, pl. pyramides (Herod.), used unaltered in the English of Sandys (1615), from which the singular pyramid was formed.

For figures of geometrical pyramids see Crystallography, and for their mensuration see Mensuration.

of the pyramids which have been found mentioned on monuments (mostly in tombs of the priests) is given in Liebelin's Chronology, p. 32. The pyramid was never a family monument, but belonged—like all other Egyptian tombs—to one person, members of the royal family having sometimes lesser pyramids adjoining the king's (as at Khufu); the essential idea of the sole use of a tomb was so strong that the hill of Gizeh is riddled with deep tomb-shafts for separate burials, often running side by side 60 or 80 ft. deep, with only a thin wall of rock between; and in one place a previous shaft has been partially blocked with masonry, so that a later shaft could be cut partly into it, mcaled with it like a twin-crystal.

The usual construction of pyramids is a mass of masonry composed of horizontal layers of rough-hewn blocks, with a small amount of mortar; and this mass in the later forms became more and more rubbly, until in the 11th Dynasty it was merely a cellular system of retaining walls of rough stones and mud, filled up with loose chips, and in the XIIth Dynasty the bulk of the mud bricks. Whatever was the hidden material, however, there was always on the outside a casing of fine stone, elaborately finished, and very well jointed; and the inner chambers were of similarly good work. Indeed the construction was in all cases so far sound that, had it not been for the spite of enemies and the greed of later builders, it is probable that every pyramid would have been standing in good order at this day. The casings were not a mere "veneer" or "film," as they have been called, but were of massive blocks, usually greater in thickness than in height, and in some cases (as at South Dashu) reminding the observer of horizontal leaves with sloping edges.

Inside of each pyramid, always low down, and usually below the ground level, was built a sepulchral chamber; this was reached in all cases by a passage from the north, sometimes beginning in the pyramid face, sometimes descending into the rock on which the pyramid was built in front of the north side. This chamber, if not cut in the rock altogether (as in Menkaure's), or a pit in the rock roofed with stone (as in Khafa'), was built between two immense walls which served for the east and west sides, and between which the north and south sides and roofing stood merely in contact, but unbonded. The gable roofing of the chambers was formed by great sloping cantilevers of stone, projecting from the north and south walls, on which they rested without pressing on each other along the central ridge; thus there was no thrust, nor were there any forces to disturb the building; and it was only after the most brutal treatment, by which these great masses of stone were cracked asunder, that the principle of thrust came into play, though it had been provided for in the sloping form of the roof, so as to delay so long as possible the collapse of the chamber. This is best seen in the pyramid of Pepi (Petrie), opened from the top right through the roof. See also the Abusir pyramids (Howard Vyse) and the king's and queen's chambers of the great pyramid (Howard Vyse, Piazzi Smyth, Petrie). The roofing is sometimes, perhaps usually, of more than one layer; in Pepi's pyramid it is of three layers of stone beams, each deeper than their breadth, resting one on another, the thirty stones weighing more than 30 tons each. In the king's chamber (Gizeh) successive horizontal roofs were interposed between the chamber and the final gable roof, and such may have been the case at Abu Roash (Howard Vyse).

The passages which led into the central chambers have usually some lesser chamber in their course, and are blocked once or oftener with massive stone portcullises. In all cases some part, and generally the greater part, of the passages slopes downwards, usually at an angle of about 26°, or 1 in 2. These passages appear to have been closed externally with stone doors turning on a horizontal pivot, as may be seen at South Dashur, and as is described by Strabo and others (Petrie). This suggests that the interiors of the pyramids were accessible to the priests, probably for making offerings; the fact of many of them having been forcibly entered otherwise does not show that no practicable entrance existed, but merely that it was unknown, as.
PYRAMID.

Of the architectural peculiarities of some particular pyramids some notice must now be given. The pyramid of Medium (figs. 1, 2) was the first true pyramid. It was begun as a mastaba, AA, like other such tombs, such as that of King Neter-khet at Beyt Khalaf. This mastaba was then enlarged by heightening it and adding a coating, and this process, repeated seven times, resulted in a high stepped mass of masonry. Such had been made before, at the step pyramid of Saqqara; but for the first time it was now covered with one uniform slope of masonry from base to top, and a pyramid was the result. The chamber is peculiar for being entered by a vertical shaft in the floor. The great pyramid (fig. 3) of Gizeh (Khufu's) is very different in its internal arrangements from any other known. The pyramid covers upwards of 15 acres, and is about 150 ft. higher than St Paul's Cathedral. As compared with St Peter's, Rome, it covers an area which is as 29 to 11, or nearly three times as much, and it is 50 ft. higher. The greater number of passages and chambers, the high finish of parts of the work, and the accuracy of construction all distinguish it. The chamber which is most normal in its situation is the subterranean chamber; but this is quite unfinished, hardly more than begun. The upper chambers, the "king's" and "queen's" were completely hidden, the ascending passage to them having been closed by pluging blocks, which concealed the point where it branched upwards out of the roof of the long descending passage. Another passage, which in its turn branches from the ascending passage to the queen's chamber, was also completely blocked up. The object of having two highly-finished chambers in the mass may have been to receive the king and his co-regent (of whom there is some historical evidence) and there is very credible testimony to a sarcophagus having existed in the queen's chamber, as well as in the king's chamber. On the details of construction in the great pyramid it is needless to enter here; but it may be stated that the accuracy of work is such that the four sides of the base have only a mean error of six-tenths of an inch in length and 12 seconds in angle from a perfect square.1

1 With respect to the construction of this and other pyramids, see Howard Vyse; on measurements of the inside of the great pyramid and descriptions, see Piazzi Smyth; and on measurements in general mechanical means, and theories, see Petrie.
chambers (one roofed with slabs, the other all rock-hewn), these chambers, however, do not run into the masonry, the whole bulk of which is solid so far as is known. This pyramid has a part of the original casing on the top; and it is also interesting as having the workmen's barracks still remaining at a short distance on the west side, long chambers capable of housing about 400 workmen. The great bulk of the rubbish from the work is laid on the south side, forming a flat terrace level with the base, and covering a steep rock escarpment which existed there. Thus the rubbish added to the broad platform which set off the appearance of the pyramids; and it has remained undisturbed in all ages as there was nothing to get out of it. The third pyramid, that of Menkaure, was eroded away from the sides by six courses of the six lowest courses. The design of it has been enlarged at one bound from a small pyramid (such as those of the family of Khufu) to the eight times the size, as it is at present, the passages needed therefore to be altered. There was no sign of enlargement: the change was sudden, from a comparatively small design to a large one. The base structure of this pyramid was ornamented with the panel decoration found on early tombs, unlike the granite sarcophagi of the two previous pyramids, which are plain. Unfortunately it was lost at sea in 1838.

An additional interest belongs to the third pyramid (of Menkaure) owing to its chamber being celled with a pointed arch (fig. 4). But it is not a true arch, the stones being mere masonry. A rather different form of arch is opposite to each other, with the underside cut to the above form (see fig. 5). Far south are the pyramids of Abusir, described in the work of Colonel Howard Vyse, and since excavated by the German excavations near Saqqara. The construction of the step-pyramid or cumulative mastaba has been noticed above, its passages peculiar and intricate, winding around the principal chamber, which is in the centre, cut in the rock some 15 feet high, and with a side chamber built in the bottom of it, which is closed with a great plug of red granite, a circular stone having fitting into a neck in the chamber roof and faced with glazed tiles bearing the name of King Neter-khet of the IVth Dynasty. That of User-ha-Fre, the first pyramid-builder, was one of the pyramids of Saqqara that are those of Unas, Pepi, Haremsha, &c. They are distinguished by the introduction of very long religious texts, covering the whole inside of the chambers and passages, these are carved in sunk hieroglyphics, painted bright green, in the white limestone. Beyond these come the pyramids of Dahshur, which are in a simple and massive style, much like those of Gizeh. The north pyramid of Dahshur has chambers roofed like the gallery in the great pyramid by successive overlappings of stone, the roof rising to a great height, with nine steps and eleven projections on each side. The south pyramid of Dahshur has still the greater part of its casing remaining, and is remarkable for being built of brick, with the four sides of the part being at the usual pyramid angle, while the upper part is but 43°. This pyramid is also remarkable for having a western passage to the chambers, which was carefully closed up. Beyond the southern group are the scattered pyramids of Lish (Senusert I.), Ilihun (Senusert II.), and Hapshet (Senusert III.), Ilihun is built with a framework of stone filled up with mud-bricks, and Hapshet is built entirely of mud-bricks, though cased with fine stone like the other pyramids.

The dimensions of the pyramids that are accurately known are in inches:

The first two closely agree to the proportion of 7 high on 11 base, approximately the ratio of a radius to its circle. And on dividing the base at Medum by 11 the modulus is 515.64, and the base of Khufu is 824.44. These moduli are 25 cubits of 20-625 and 40 cubits of 20-611; so it appears that the form was of the same type as the two preceding, but with more pyramids and a larger area respectively.

Beyond these already described there are no true pyramids, but we will briefly notice those later forms derived from the pyramid. At Thebes some small pyramids belong to the kings of the Xith Dynasty; the tomb-chamber is in the rock below. The size is under 50 ft. square. These are not oriented, and have no horizontal entrance, quite unlike the narrow pipe-like passages sloping down into the regular pyramids (see Mariette, in Bibl. arch. 1868). In Ethiopia, at Gebel Barkal, are other so-called pyramids of a very late date, are nearly all hewn porches; the simplicity is lost amid very dubious decorations; and they are not oriented. They are all very acute, and have flat tops as if to support some ornament. The sizes are but small, varying from 23 to 88 ft. square. In Gebel Barkal, and 7 to 63 ft. square at Meroe. The interior is solid throughout, the windows which appear on the sides being useless architectural members (see Hoskin's Ethipia, 148, &c.). The structures sometimes called pyramids at Bahimu in the Fayum, and Gizeh, and perhaps at Meroe, are probably large enclosed courts with sloping sides, in the centres of which were two seated statues raised on pedestals high enough to be seen over the walls of the courts. This form would appear like a pyramid with a square or octagonal base, and with vertical sides sloping at a small angle to the roof. These are well described in the Illustrated London News, XXXVII. 282. The details of the transport and management of the large stones remain still to be explained.

PYRAMIDION (diminutive of "pyramid"), an architectural term for the copper-gilt casing covering the apex of an obelisk, and generally extended to its upper termination of pyramidal form.

PYRAMUS AND THISBE, the hero and heroine of a Babylonian love-story told by Ovid (Metam. iv. 55-465). Their parents refused to consent to their union, and the lovers used to converse through a chink in the wall separating their houses. At last they resolved to flee together, and agreed to meet under the mulberry tree near the tomb of Ninus. Thisbe was the first to arrive, but, terrified by the lion, took to flight. In her haste she dropped her veil, which the lion, believing to be perfumes with the blood of an ox, Pyramus believing that she had been devoured by the lion, stabbed himself. Thisbe returned to the rendezvous, and finding her lover mortally wounded, put an end to her own life. From that time the fruit of the mulberry, previously white, was always black.

PYRARGYRITE, a mineral consisting of silver sulpharionimite, AgSbS3, known also as dark red silver ore, an important source of the metal. It is closely allied to, and isomorphous with, the corresponding sulpharsenite, known as proustite (g.v.) or light red silverore. "Ruby silver" or red silver ore (German Rotgutt Original) was mentioned by G. Agricola in 1546, but the two species so closely resemble one another that they were not completely distinguished until chemical analyses of both were made by J. L. Proust in 1804.
PYRAZINES—PYRAZOLES

Both crystallize in the ditrigonal pyramidal (hemihoric-hemihedral) class of the rhombohedral system, possessing the same degree of symmetry as tourmaline. Crystals are perfectly developed and are usually prismatic in habit; they are frequently attached at one end, the termination being the result of having been broken off by the monoclinic oblique striations on the prism faces directed towards one end only of the crystal. Twinning according to several laws is not uncommon. The angles are nearly the same in the two species; the molecule of pyrazine being 71° 25′, and pyrazycarbazole in proustite. The hexagonal prisms of pyrargyrite are usually terminated by a low hexagonal pyramid (310) or by a drusy basal plane. The colour of pyrargyrite is usually greyish-black and the lustre sometimes large and pearly. Pyrargyrite and quartz, and thin splinters are deep ruby-red by transmitted light, hence the name, from Gr. σευδος (fire) and ψηφος (silver), given by E. F. Glocker, in 1831. The streak is purplish-red, this differing markedly from quartus, which has a red streak and the habit of distinguishing the two minerals. The hardness is 2 1/2. and the specific gravity 5.85: the refractive indices and birefringence are very high, nα = 3.084, ε = 2.881. There is no very distinct cleavage and the fracture is conchoidal. The mineral occurs in metalliferous veins with calcite, argentiferous galena, native silver, native arsenic, &c. The best crystallized specimens are from St Andreasberg in the Harz, Freiberg in Saxony, and Guanajuato in Mexico. It is not uncommon in many silver mines in the United States, and rare as distinct crystals; and it has been found in some Cornish mines.

The "red silver ores" afford a good example of isomorphism, they rarely form mixtures; pyrargyrite rarely contains as much as one per cent. of quartz. The metallic silver and the silver of antimony in proustite. Dimorphous with pyrargyrite and proustite respectively are the rare monoclinic species pyrostipilite or freibende (Ag₃Sb₂) and xanthocoine (Ag₃AsS₃); these four minerals thus form an isomorphic group. (L. J. S.)

PYRAZINES, PYRAZINES, or PARAPYRAZINES, in organic chemistry, a group of compounds containing a ring system composed of 4 or 5 atoms, 4 being nitrogen and the other 1, 2 or 3 being in the para position. The di- and tri-methyl derivatives are found in the fuel oil obtained by fermentation of beet-root sugar (E. C. Morin, Comptes rendus, 1888, 106, p. 360).

They were first prepared synthetically by reducing the iso-nitrosoketones. They may also be prepared by the internal condensation of α-aminoaldehydes or α-aminoalkanes in the presence of a mild oxidizing agent, such as mercuric chloride or copper sulphate in boiling alkaline solution (L. Wolff, Ber., 1893, 26, p. 1830; S. Gabriel, ibid. p. 2207); and by the action of ammonia on e-halogen ketonic compounds (W. Staedel and L. Rüghemer, Ber., 1876, 9, p. 563; V. Meyer and E. Braun, Ber., 1888, 21, p. 19). They are also formed when grape sugar is heated with ammonia or when glycine is heated with ammonium chloride and ammonium phosphate (C. Stecher, Journ. phys. Chem., 1895, 2, p. 439, and 1896, 3, p. 485). They are feeble bases which distil uncondensed. They are mostly soluble in water and somewhat hygroscopic in character. Their salts are easily dissociated. They form characteristic compounds with mercuric and aurochlorides. Their alkyl derivatives readily oxidize to pyrazine carboxylic acids. Pyrazine, CH₄N₂, crystallizes from water in prisms, which have a heliotrope odour. It melts at 55°C. and boils at 115°C. It may be obtained by elimination of carbon dioxide from the pyrazine dicarboxylic acid formed when quinoline is oxidized by potassium permanganate (S. Gabriel). 2:5 Dimethylpyrazine, or ketene, C₆H₅(NOCH₃)₂, is obtained by reducing isonitrosoacetone, or by heating glycine with ammonium chloride and ammonium phosphates, in 3:1023 (Kg. de H. Pfeiffer and S. Gabriel, Ber., 1893, 5, p. 408). Two classes of dihydroxyazines are known, namely the 1:4 and 2:3 dihydro-compounds, corresponding to the formulae II. and III., pyrazine being I. —

HC-N°CH HC-N°CH HC-N°CH HC-N°CH (Pyrazine) II (1:4 dihydro) III (2:3 dihydro) IV (Piperazine).

Those of the former type are obtained by condensing α-bromketones with diethylamine (A. T. Mason). Those of the latter type, condensing alkylic diamines with α-diketones. The 2:3 derivatives are somewhat unstable compounds, since on heating they readily give up two hydrogen atoms. Tetrahydroazines of the 1:2:3:4 type have also been obtained (L. Garzini, Ber., 1891, 24, 956 R). Hexahydroazines or piperazine (formula IV), also known as diethylic dianmine, may be prepared by reducing pyrazine, or, better, by combining aniline and ethylene bromide to form diphenyl diethylenediamine, the dinitro compound of which hydrolyses to para-dinitrosophenol and piperazine. It is a strong base, melting at 104°C. and boiling at 145°C—146°C. It is used in medicine on account of the high solubility of its salt with uric acid.

PYRAZOLES, in organic chemistry, a series of heterocyclic compounds containing a five-membered ring consisting of three carbon atoms united to two nitrogen atoms, thus: the derivatives are orientated from the imino group, the second position being at the other nitrogen atom. Pyrazole, CH₂N₂, was obtained by E. Buchner (Ber., 1889, 22, p. 2165) by heating pyrazole 3:4:5-tricarboxylic acid, and by L. Balbiani (Ber., 1890, 23, 30) by heating cyanhydrin with hydrazine hydrate in the presence of zinc chloride:

C₄H₄O₂+2NH₂=CH₂N₂+2NH₂·HCl+H₂O+H₂

It may also be prepared by the union of diazomethane with acetylone (H. v. Peckmann, Ber., 1897, 31, p. 2950), and by warming the acetate of propargyl aldehyde with an aqueous solution of hydrazine sulphate (Ber., 1893, 36, p. 3662). It crystallizes in colourless needles, is very stable and behaves as a weak base. It does not combine with the alkyl iodides. Ammoniacal silver nitrate gives a precipitate of pyrazole silver.

The homologues of pyrazole may be obtained by digesting β-diketones or β-keto-alkyldehydes with phenylhydrazine; by heating the phenylhydrazones of some monoketones with acetic anhydride; by reducing the diones of pyrazoles or pyrazolines with hydrogen, or by the use of very strong reducing agents the ring is ruptured and trimethylendiamine derivatives are formed. They yield substitution derivatives with the halogens, bromine being the most effective; the ring is replaced by halogen or by the action of phosphorus oxychloride.

The pyrazole carboxylic acids may also be obtained by condensing β-diketone or oxymethylene ketone carboxylic esters with alkylating agents, such as acid chlorides. The N-phenyle derivatives give pyrazolines, or by the use of very strong reducing agents the ring is ruptured and trimethylendiamine derivatives are formed. They yield substitution derivatives with the halogens, bromine being the most effective; the ring is replaced by halogen or by the action of phosphorus oxychloride.

The pyrazolone-3 derivatives may also be obtained by condensing β-diketone or oxymethylene ketone carboxylic esters with alkylating agents, such as acid chlorides. The N-phenyle derivatives give pyrazolines, or by the use of very strong reducing agents the ring is ruptured and trimethylendiamine derivatives are formed. They yield substitution derivatives with the halogens, bromine being the most effective; the ring is replaced by halogen or by the action of phosphorus oxychloride.
The pyrazolines are tetrahydropyrazoles. The N-phenyl derivative, from sodium phenylhydrazide and trimethylene dibromide, is an oil which readily oxidizes to phenylpyrazoline on exposure. The corresponding keto-derivatives, or pyrazolones, are produced by the action of hydrates on the β-bromo acryloxy acids. Isomer compounds may arise here when phenylhydrazine is used, the keto-group taking either the 3 or 5 position; thus with β-lodophenylacetic 1-phenylpyrazolidine-5 is formed, whilst potassium β-lodophenylacetate gives the 3-compound. Isomers of this type may be distinguished by the fact that the pyrazolone-5 compounds are basic, whilst the 3-compounds are acidic. The simplest member of the series, pyrazolone-5, is a liquid which is formed by the action of hydrate on acrylonitrile. The 3-5-pyrazolones are the cyclic hydrizides of the malonic acid series.

Thiopyrazoles have been obtained by A. Michaelis (Ann., 1904, 331, p. 197; Ber., 1904, 37, p. 2724) by the 18. Crystallization of the alcoholic solution of the methyl chloride or iodide of phenylmethylchloropyrazole on a solution of an alkaline hydrosulphite into which carbon bisulphide has been passed; or by the action of sodium thiosulphate on antipyrine hydrochloride or a similar compound. The simplest member of the group is probably to be represented as

\[ \text{HC} : (\text{SH}) \rightarrow \text{N} - \text{C}_2 \text{H}_5 \text{ or } \text{HC} - \text{CN} \rightarrow \text{N} - \text{C}_2 \text{H}_5 \]

The crude solid product from the tar distillate is digested with carbon bisulphide to dissolve the pyrene, the solution filtered and the solvent evaporated. The residue is dissolved in alcohol and to the cold saturated solution a cold alcoholic solution of picric acid is added. The picroate so formed is then decomposed by ammonia. On its separation from the "Stupp" fat see E. Bamberger and M. Philip, Ann., 1887, 240, p. 161. It crystallizes in monoclinic plates which melt at 148-149°C. Chronic acid oxidizes it to pyrene quinone, \( \text{C}_9\text{H}_4\text{O}_2 \), and pyreic acid, \( \text{C}_8\text{H}_4\text{O}_4 \). The picroate, which is easily soluble in benzene, crystallizes in long red needles melting at 222°C. When heated with hydriodic acid and phosphorus to 200°C it yields a hexahydride. It has been obtained synthetically by M. Freund and H. Michaelis (Ber., 1897, 30, p. 1383) by distilling thebenol over zinc dust in a stream of hydrogen, or by the action of hydriodic acid and phosphorus at 220°C on thebenol.

**PYRENEES** (Span. *Pirineos*, Fr. *Pyrénées*), a range of mountains in south-west Europe, separating the Iberian Peninsula from France, and extending for about 240 m., from the Bay of Biscay to Cape Creus, or, if only the main crest of the range be considered, to Cape Cébrère, on the Mediterranean Sea. For the most part the main crest constitutes the Franco-Spanish frontier; the principal exception to this rule is formed by the valley of Aran, which belongs orographically to France but politically to Spain. The Pyrenees are conventionally divided into three sections, the central, the Atlantic or western, and the eastern. The central Pyrenees extend eastward from the Port de Canfranc to the valley of Aran, and include the highest summits of the whole chain, Aneto or Pic de Néthou (11,168 ft.) in the Maladetta ridge, Posets (11,047 ft.), and Mont Perdido or Monte Perdido (10,997 ft.). In the Atlantic Pyrenees the average altitude gradually diminishes westward; while in the eastern Pyrenees, with the exception of one break at the eastern extremity of the Pyrénéen Ariégeois, the mean elevation is maintained with remarkable uniformity, till at last a rather uniform declivity occurs in the portion of the chain known as the Alberes. This threefold division is only valid so far as the elevation of the Pyrenean chain is concerned, and does not accurately represent its geological structure or general configuration. The careful examination of the chain by members of the English and French Alpine Clubs has since 1880 considerably modified the views held with respect to its general character; the southern versant, formerly regarded as inferior in area, has been proved to be the more important of the two. It has been recognized, as shown in the maps of MM. Schrader, de St Sand and Wallon, that, taken as a whole, the range must be regarded, not as formed on the analogy of a fern-frond or fish-bone, as the lateral ridges running down to the two opposite plains, but rather as a swelling of the earth's crust, the culminating portion of which is composed of a series of primitive chains, which do not coincide with the watershed, but cross it obliquely, as if the ground had experienced a sidewise thrust at the time when the earth's crust was ridged up into the long chain under the influence of contraction. Both the orderly arrangement of these diagonal chains, and the fact which exists between the tectonic and geological phenomena are well shown in the geological and hypsometrical maps published in the *Annaire du Club Alpin français* for 1891 and 1892 by MM. Schrader and de Margerie. The primitive formations of the range, of which little beyond the French portions had previously been studied, are shown to be almost all continued diagonally on the Spanish side, and the central ridge thus presents the appearance of a series of wrinkles with an inclination (from north-west to south-east) greater than that of the chain as a whole. Other less pronounced wrinkles run south-west to north-east and intersect the former series at certain points, so that it is by alternate digressions from one to the other series that the irregular crest of the Pyrenees acquires its general direction. Far from having impressed its own direction on the orientation of the chain at large, this crest is merely the resultant of secondary agencies by which the primitive mass has been eroded and lessened in bulk. Though its importance from a hydrographic point of view is still considerable, its geological significance is practically nil.

**Geology.**—The Pyrenees are divided by E. de Margerie and F. Schrader into a number of longitudinal zones. The central zone consists of Primary rocks, together with great masses of granitic. It forms most of the highest summits, but west of the Pic d'Aubisque it is represented by a broad flanks, the zone of the Ariège, consisting of Lower Cretaceous and Jurassic beds, together with granitic masses; (2) the zone of the Petites Pyrénées, Upper Cretaceous and Eocene; (3) the zone of the Cévennes, consisting of Eocene and Primary rocks. On the Spanish side, from north to south, are (1) the zone of Mont Perdu, Upper Cretaceous and Eocene; (2) the zone of Aragon and Eocene; and (3) the zone of the Cévennes. Two flanks, they do not correspond. The zone of the Corbières has no equivalent in Spain, while in France there is no definite zone of Eocene like that of Aragon. The zone of the Petites Pyrénées, however, is clearly homogeneous with that of the Spanish Pyrenees. Large masses of granite or have been brought upon nearly horizontal faults (thrust-planes) over the edges of both beds with which they originally had no connexion. In the region of Salies-du-Salat, for example, patches of Trias lie discordantly upon the edges of the Cretaceous and Tertiary beds. Several other similar cases...
have been described; but denudation has been carried further in the western Alps, and accordingly the masses overlying the thrust-planes have been more completely removed (q.v.).

The earth movements which raised the Pyrenees appear to have been synchronous with those forming the eastern Alps, but the principal folding took place. The Pyrenees are therefore contemporaneous with the Alps; but they appear to have escaped the Miocene disturbances which affected the latter.

The Pyrenees are a series of Pliocene and Miocene mountains gently inclined near the centre but longitudinal everywhere else, is illustrated by the courses of the streams which flow down towards Spain. On the French side most of the longitudinal valleys have disappeared; and those which remain today have been described as sending out transverse spurs, the more important slope remaining unknown. It is, however, still possible to distinguish some traces of this formation towards the east, where atmospheric denudation has been less effective.

On the French side the principal streams, after cutting their way through the highest zone at right angles to the general direction of the range, become involved half-way to the plains in great longitudinal folds, from which they make their escape only after traversing long distances without finding an outlet.

The importance shown to attach to the Spanish versant has greatly modified the values formerly assigned to the area and mean elevation of the Pyrenees. Instead of the 13,440 sq. m. formerly put down for the total, M. Schrader found the area to be 21,044 sq. m. Of this total 6390 sq. m. fall to the northern slope and 14,654 sq. m. i.e., more than double, to the southern, the difference being mainly due to the zone of plateaux and sierras. The mean elevation, estimated to be 21,044 ft. (6400 m.), sensibly diminished by the addition of that zone to the system, and it must now be placed at only 1900 metres (3930 ft.) for the range as a whole; so important a part is played by the above-mentioned plateaux of small elevation in a chain whose highest summit reaches 11,168 ft. (3400 m.), while the passes show a greater altitude than those of the Alps.

Four conspicuous features of Pyrenean scenery are the absence of great lakes, such as fill the lateral valleys of the Alps, the rarity and great elevation of passes; the large number of the mountain torrents locally called gapes, which often form lofty waterfalls, surpassed in Europe only by those of Scandinavia; and the frequency with which the upper end of a valley assumes the form of a semicircle of precipitous cliffs, locally called a cirque. The highest waterfall is that of Gavarnie (1515 ft.), at the level of the town of Bagneres de Luchon, and the Cirque de Gavarnie, in the same valley, is perhaps the most famous example of the cirque formation.

Not only is there a total lack of those passes, so common in the Alps, which lead across the great mountain chains at a far lower level than that of the neighbouring peaks, but between the two extremities of the range, where the principal highroads and the only railways run between France and Spain, there are only two passes practicable for carriages—the Col de la Perche, between the valley of the Têt and the valley of the Segre, and the Col de Somport or Pot de Canfranc, on the old Roman road from Saragossa to Oloron.

Projects for further railway construction, including the building of tunnels on a vast scale, have been approved by the French and Spanish governments (see Spain: Communications).

The metallic ores of the Pyrenees are not of great importance, though there are considerable iron mines at Vic de Sus in Ariège and at the foot of Canigou in Pyrénées-Orientales. Coal deposits are the most important. Gold and silver workings are similar to those in the Spanish slopes but the French side has numerous beds of lignite. Mineral springs are abundant and very remarkable, and specially noteworthy are the hot springs, in which the Alps, on the contrary, are very deficient. The hot springs, among which those of Bagnères de Luchon and Eaux-Chaudes may be mentioned, are sulphurous and mostly situated high, near the contact of the granite with the stratified rocks. The lower springs, such as those of Bagnères de Bigorre (Hautes-Pyrénées), Rennes (Aude) and Campange (Aude), are mostly sudenic and very not very.

The amount of the precipitation, including rain and snow, is much greater in the western than in the eastern Pyrenees, which leads to a marked contrast between these sections of the chain in more than one respect. In the first place, the eastern Pyrenees are without glaciers, the quantity of snow falling there being insufficient to lead to their development. The glaciers are confined to the northern slopes of the central Pyrenees, and do not descend, like those of the Alps, far down in the valleys, but have their greatest length in the direction of the mountain-chain. They form, in fact, a narrow zone near the crest of the highest mountains. Here, as in the other great mountain ranges of central Europe, there are evidences of a much wider extension of the glaciers during the Ice age. The case of the glacier in the valley of Arêgles in the department of Hautes-Pyrénées is the best-known instance. The snow-line varies in different parts of the Pyrenees from 8800 to 9200 ft. above sea-level.

A still more marked effect of the preponderance of rainfall in the western half of the chain is seen in the aspect of the vegetation. The lower mountains in the extreme west are very well wooded, but the extent of forest declines eastwards, and the eastern Pyrenees are peculiarly wild and naked, all the more since it is in this part of the chain that granite masses prevail. There is a change, moreover, in the composition of the flora in passing from west to east. In the west the flora, at least in the north, resembles that of central Europe, while in the east it is distinctly Mediterranean in character, though the difference of latitude is only about 1°, on both sides of the chain from the centre whence the Colbières stretch north-eastwards towards the central plateau of France. The Pyrenees are relatively as rich in endemic species as the Alps, and among the most remarkable instances of that endemism is the occurrence of the sole European species of Dioscorea (yam), the D. pyrenatica, on a single high station in the central Pyrenees, and that of the monotypic genus Xeratidia, only on a high alpine pass between the Val d’Eynès and Catalonia. The genus most abundantly represented in the range is that of the saxifrages, several species of which are here endemic.

In their fauna also the Pyrenees present some striking instances of endemism. There is a distinct species of ibex (Capra pyrenatica) confined to the range, while the Pyrenean desman or water-mole (Myogale pyrenaica) is found only in some of the streams of the northern slopes of these mountains, the only other member of this genus being confined to the rivers of southern Russia. Among the other peculiarities of the Pyrenean fauna are blind insects in the caverns of Arize, the principal genera of which are Anoplophalus and Adelops.

The ethnology, folk-lore, institutions and history of the Pyrenean region form an interesting study: see Andorra; Aragon; Basques; Bear; Catalonia; Navarre.

Joume, Pyrénées et Alpes (1905); J. Geology, in addition to the papers cited above, A. Bressou, Études sur les formations des Hautes et Basses Pyrénées (Paris, Ministère des Travaux Publics, 1903); L. Cartes, La Géologie des Pyrénées françaises (Paris, Min. des T., 1903 & 1904); A. Bernaldez, Atlas de Geografía Politica y Fisica de los Pirineos (Paris, Min. des Tr. P., 1904); and for climate and flora T. Cook, Handbook to the Health Resorts on the Pyrenees, &c. (1905), and J. Bentham, Catalogue des plantes indigènes des Pyrénées et de Bas-Languedoc (1826).

PYRENEES-ORIENTALES, a department of south-western France, bordering on the Mediterranean and the Spanish frontier, formed in 1790 of the old province of Roussillon and of small portions of Languedoc. The population, which includes many Spaniards, numbered 213,171 in 1906. Area, 1593 sq. m. km.

The department is bounded N. by Ariège and Aude, E. by the Mediterranean, S. by Catalonia and W. by the republic of Andorra. Its borders are marked by mountain peaks, on the north by the Corbières, on the north-west and south-west by the eastern Pyrenees, and on the south-east by the western Pyrenees. Along the eastern Pyrenees near Cape Cerbera. Spurs of these ranges project into the department, covering its whole surface, with the exception of the alluvial plain of Roussillon, which extends inland from the sea-coast. Deep and sheltered bays in the vicinity of Cape Cerbera and other flat sandy beaches, along which lie lagoons separated from the sea by belts of sand. The lagoon of St Nazaire is 2780 acres in extent, and that of Leucate on the borders of Aude is 19,300 acres. Mont Canigou (1937 ft.), though surpassed in height by the Carlite Peak (2955 ft.), is the most remarkable mountain in the eastern Pyrenees, since it stands out to almost its full height above the plain, and exhibits with great distinctness the succession of zones of vegetation. From the base to a height of 1400 ft. are found the orange, the aloes, the clematis, the pomegranate,
and the olive; the vine grows to the height of 1800 ft.; next come the chestnut (2625 ft.), the rhododendron (from 4330 to 8330 ft.), pine (6400 ft.), and birch (6960 ft.); while stunted junipers grow to the summits.

The drainage of the department is shared by the Tet and the Tech, which rise in the Pyrenees, and the Agly, which rises in the Corbières. All three flow eastwards into the Mediterranean. The Aude, the Ariège (an affluent of the Garonne) and the Ségre (an affluent of the Ebro) also take their rise within the department and include a small part of it in their respective basins. The Tet rises at the foot of the Carlitge Peak and descends rapidly into a very narrow valley before it debouches at Ille (between Prades and Ceret). It is navigable for small vessels on the lower stretches, over a wide pebbly bed and supplies numerous canals for irrigation. It is nowhere navigable, and its supply of water varies much with the seasons, the whole or that it is not fed by any glacier. The Agly, which soon after its rise traverses the magnificent gorge of St. Roque, has a very large area, and near its mouth passes Rivesalt (famous for its wines), serves almost exclusively for irrigation. The Tech, which after the Tet is the most important river of the department, flows through Vallespir (valles aspera), which, notwithstanding its name, is a green valley, clothed with wood and alder; in industry; in its course the river passes Prats de Mollo and Arles-sur-Tech, before reaching Amélie-les-Bains and Céret. In the lowlands the climate is that of the Mediterranean, characterized by mild winters, dry summers and short and sudden rain-showers. Amélie-les-Bains is much frequented on account of its mild climate and sheltered position. The thermometer ranges from 85° to 95° F. in summer, and in winter only occasionally falls as low as 26° or 27°.

The vegetation is confined to the valleys and the hills on which the rain falls, and turns towards the hills. The most common wind is the tramontane from N.N.W., as violent as the mistral of Provence and extremely parching. The maritima blows from the S.S.E.

The cultivated land in Pyrénées-Orientales is devoted to wine-growing, market-gardening and fruit culture, the production of cereals being comparatively unimportant. The main source of wealth to the department is its wine, of which some kinds are strongly alcoholic and others are in request as liqueur wines (Rivesaltes, Banyuls). The cultivation of early vegetables (artichokes, asparagus, tomatoes, green peas), which is specially flourishing in the irrigated lowlands, and fruit-growing (peaches, apricots, plums, pears, quinces, pomegranates, almonds, apples, cherries, walnuts, chestnuts), which is chiefly carried on in the river valleys, yield abundant returns. The woods produce timber for the cabinet-maker, cork, and bark for tanning. Large flocks of sheep feed in the pastures of the Pyrenees and Corbières; the keeping of silkworms and bees is also profitable. In iron Pyrénées-Orientales is one of the richest departments in France, the greater part of the ore being transported to the interior. Lignite and various kinds of stone are worked. The mineral waters are much resorted to. Amélie-les-Bains has hot springs, chalybeate or sulphurous. In the arrondissement of Ceret there are also the establishments of La-Preste-les-Bains, near Prats de Mollo, with hot sulphurous springs, and of Le Boulou, the Vicinity of the Pyrenees. Near Prades are the hot sulphurous springs of Moigot, and a little north of Mont Canigou are the hot springs of Vernet, containing sodium and sulphur. In the valley of the Tet the sulphurous and alkaline springs of Thuey reach a temperature of 172° F. The baths of Les Escaldas, near Montlouis, are hot, sulphurous, and carbonic acid, and the makers of the securities of the department include the making of whip-handles, corks, cigarette paper, barrels, bricks, woolen and other cloths, and estpadilles (a kind of shoe made of coarse cloth with esparto soles). Of the ports of the department Port Vendres alone has any importance. Imports include timber, Spanish and Algerian wine, cereals, coal; among the exports are wine, timber, vegetables, fruit, honey, oil and manufactured articles. The department is served by the Southern railway. The chief route across the Pyrenees is from Perpignan by way of Montlouis, a fortified place, to Puigcerda, in the Spanish province of Gerona, through the pass of La Perche, skirting in the French department an enclave of Spanish territory.

Three other roads run from Perpignan to Figueras through the passes of Perthus (defended by the fort of Belle garde), Banyuls and Balstres, the last-named being traversed by a railway. The chief towns of the three arrondissements are Perpignan, Ceret and Prades: there are 17 cantons and

232 communes. The department constitutes the diocese of Perpignan, and is attached to the appeal court and the academy of Montpellier and to the region of the XVI. army corps, of which Perpignan is the headquarters.

Perpignan, the capital town and a fortress of the first class, Amélie-les-Bains and Eln are the more noteworthy places, and are treated separately. Rivesaltes (5448) is the most populous town after Perpignan. Other places may be mentioned. Planès has a curious church, triangular in shape, and of uncertain date. Popular tradition ascribes to it a Moslem origin. The church and cloister at Arles-sur-Tech are also of the 12th century. Boule-d'Amont has a Romanesque church which once belonged to the Augustine abbey of Sarrabona. It is peculiar in that its aisles open out into lateral porches, instead of communicating with the nave. The church of Castell, which is of the 11th century, is a relic of the ancient abbey of St. Martin de Canigou. At St. Michel-de-Guix, near Prades, are fine ruins of a Benedictine abbey. The hamlet of Fongromeu, near Odeillo, has a chapel with a statue of the Virgin, which was visited by numerous pilgrims.

**PYRETHRUM**

Pyrethrum. The pyrethrum grows best in soil of a loamy texture; this should be well manured and deeply trenched up before planting, and should be mulched in the spring by a surface dressing of half-decayed paper or straw. If the plants are to be divided, the side shoots being taken off early in spring rather than in autumn, with a portion of roots attached. Plants disturbed in summer frequently dies during the winter. They may be placed either in separate beds or in the mixed flower borders as may be required. In beds they can be supplemented by fine cut leaves and large flower heads, having a ray of deep rose-coloured foliage, creating the attractive character of them. The most suitable months for the introduction of the pyrethrum are during the months of May and June, as well as later, and are always most welcome ornaments for the flower borders, and useful for cutting for decorative purposes. There are numerous varieties, both single and double-flowered, in cultivation.

The pyrethrum grows best in soil of a loamy texture; this should be well manured and deeply trenched up before planting, and should be mulched in the spring by a surface dressing of half-decayed paper or straw. If the plants are to be divided, the side shoots being taken off early in spring rather than in autumn, with a portion of roots attached. Plants disturbed in autumn frequently dies during the winter. They may be placed either in separate beds or in the mixed flower borders as may be required. In beds they can be supplemented by fine cut leaves and large flower heads, having a ray of deep rose-coloured foliage, creating the attractive character of them. The most suitable months for the introduction of the pyrethrum are during the months of May and June, as well as later, and are always most welcome ornaments for the flower borders, and useful for cutting for decorative purposes. There are numerous varieties, both single and double-flowered, in cultivation.

**PYRG** (mod. S. S. Savona), an ancient town of Etruria, Italy, on the south-west coast 9 m. W.N.W. of Caere. The name is Greek (pyrigo, towers), and the place of considerable antiquity. Remains of its defensive walls exist in polygonal blocks of limestone and sandstone, neatly jointed. They enclosed a rectangular area some 200 yds. in width and at least 220 yds. in length. The south-west extremity has probably been destroyed by the sea. It contained a rich temple of Luecothea, the foundation of which was ascribed to the Pelasgi. It was plundered by Dionysius in 384 B.C. Later it became dependent on Caere, though it is not probable that it was originally merely the harbour of Caere; Alism (279) is a good deal nearer (5 m. south). The Romans planted a colony here, which is first mentioned in 197 B.C. Later still it supplied fish to the capital, and became a favourite summer resort, as did also Punicum (S. Marinella) 5 m. to the north-west, where there are many remains of villas. Both were stations on the coast road (Via Aurelia). See H. Dennis, *Cities and Cemeteries of Etruria*, i. 289. (London, 1865.)
PYRGOS, a town of Greece, in the province of Elis and Achaia, 43 m. S.S.W. of Patras. It is the third town in importance in the Peloponnese, and is connected with its harbor, Kalamata, 13 m. distant, and also with Patras and Olympia, by rail. It has frequently been injured by earthquakes. Pop. (1897), 13,690.

PYRINE, CH₂N₂, an organic base, discovered by T. Anderson (Trans. Roy. Soc. Edin., 1851, 20, p. 251) in bone oil. It is also found among the distillation products of bituminous coal, lignite, and various shales, and has been detected in fusel oil and crude petroleum. It is a decomposition product of various alkaloids (nicotine, sparteine, cinchicine, &c.), being formed when they are strongly heated either alone or with zinc dust. It may be synthetically prepared by distilling allyl ethylamine over heated lead oxide (W. Königs, Ber., 1879, 12, p. 2341) by passing a mixture of acetylene and hydrocyanic acid through a red-hot tube (W. Ramsay, Ber., 1877, 10, p. 739); by heating pyrrol with sodium methylate and methyl iodide to 200° C. (M. Dennstedt and J. Zimmermann, Ber., 1885, 18, p. 3310); by heating isoamyl nitrate with phosphorus pentoxide (E. T. Chapman and M. H. Smith, Ann., 1888, Suppl. 6, p. 529); and by reducing pyridine in acetic acid solution with silver acetate (J. Tade, Ber., 1892, 25, p. 1610). The amount of pyrindine produced in most of these processes is very small, and the best source for its preparation is the "light-oil" fraction of the coal-tar distillate. The basic constituents are removed by dilute sulphuric acid, the acid layer removed, and the bases liberated by alkali, separated, dried, and fractionally distilled.

Pyrine is a colourless liquid of a distinctly unpleasant, penetrating odour. It boils at 114.5° C., and is miscible with water in all proportions. It is a tertiary base, and combines readily with the alkyl halides to form pyridinium salts. Nascent hydrogen reduces it to pyrrolidine, C₆H₅N (see below), whilst hydric acid above 300° C. reduces it to n-pentane (A. W. Hofmann, Ber., 1883, 16, p. 590). It is a very stable compound, chronic and nitric acids being without action upon it, whilst the halogens only yield substitution derivatives with difficulty. It reacts with sulphuric acid only at high temperatures, yielding a sulphonic acid. It forms addition compounds with mercuric and auric chlorides. On the constitution of the pyridine nucleus, see Körner, Gior. dell' accad. di Palermo, 1869, and C. Riedel, Ber., 1883, 16, p. 1600. As regards the isomerism of the pyridine substitution products, three mono-derivatives are known, the different positions being indicated by the Greek letters α, β, and γ, as shown in the inset formula. This formula also allows of the existence of six di-derivatives, six tri-derivatives, three tetra- and one penta-derivative, when the substituent groups are identical; all of which are in agreement with known facts.

The three monochloropyridines are known, the α and γ compounds resulting from the action of phosphorus pentachloride on the corresponding oxypyridines, and the β compound from the action of chloroform on potassium pyrrol. α-Nido-pyridine, C₆H₅N-ClH₃, is formed by heating 5-aminopyridine-2-carboxylic acid. It is a crystalline compound which melts at 56° C. and boils at 205° C. It can only be diazotized in the presence of concentrated sulphuric acid, and even then the free diazotium salt is not stable, readily passing in the presence of water to α-oxopyridine. β-Amino-pyridine is obtained by heating β-pyridyl urethane with fuming hydrochloric acid until no more carbon dioxide is liberated (T. Curtius and E. Mohr, Ber., 1898, 31, p. 2493), or by the action of bromine and caustic soda on the amide of nicotinic acid (F. Pollak, Monats., 1895, 16, p. 59). It melts at 64° C. and boils at 250° C. The anilino-pyridines are readily soluble in water, and resemble the aliphatic amines in their general chemical properties.

The oxypyridines may be prepared by distilling the corresponding oxypyridine-carboxylic acids with lime, or by fusing the pyridine-carboxylic acids with caustic potash. The mono-oxypyridines are easily soluble in water and possess only feebly basic properties. The β compound is hydroxyl in character, whilst the α and γ derivatives behave frequently as if they possess the tautomeric keto structure, yielding according to the conditions of the experiment either N- or O-ethers (H. v. Pechmann, Ber., 1895, 28, p. 1624), thus corresponding to the formulæ—

The homologues of pyridine may be synthesized in various ways. One of the most important is the so-called "collidine" synthesis of A. Hantzsch (Ann., 1892, 215, p. 1; Ber., 1892, 15, p. 2914), which consists in the condensation of two molecules of acetoo-acetic ester with one of an aldehyde and one of ammonia:

R⁻CO·CH₂⁻R'⁻CHO + CH₃⁻CO⁻R'⁻H → R⁻O⁻C⁻CH₂⁻R⁻CO⁻R'⁻H + CH₃⁻CO⁻H

The resulting dihydro-compound is then oxidized with nitrous acid, the ester hydrolysed and the resulting dihydro-lime; carbon dioxide is eliminated and a trisubstituted pyridine of the type is obtained. The reaction is apparently a general one for all aldehydes. On the course of the reaction see also C. Beyer, Ber., 1891, 24, p. 1662, and E. Knoevenagel, Ber., 1898, 31, p. 738. In this reaction the proportions of aldehyde and acetoo-acetic ester may be interchanged and α and β disubstituted pyridines are then obtained. Of the other methods for preparing pyridine homologues mention may be made of the discovery by A. Landerburg that the pyridinium alkyl iodides rearrange themselves when strongly heated and yield α and γ alkyl pyridines (Ber., 1883, 16, p. 1410 seq.; Ann., 1888, 247, p. 1). S. Kühnemann prepared γ-substituted dihydro-lime by condensing alkyl-4-carboxy-4-glutonic esters with ammonia. The following compounds are obtained:

(R'O₃CO)₂⁺⁻C⁻R⁻CH⁻(CO₂R)⁻ + R⁻O⁻C⁻CR⁻CH⁻CO⁻R'⁻H → R⁻O⁻C⁻CR⁻CH⁻CO⁻R'⁻H + OC⁻NH⁻CO⁻HO⁻C⁻N⁻C⁻OH

M. Scholtz (Ber., 1895, 28, p. 1726) prepared αa methylpyrpyridine by distilling cinnamic acid esters, 5C[H₂CH₂CHRCH₃CH₃] + H₂CO → H₂C⁺⁻CH₂⁻CH⁻CH⁻(N·OH)⁻CH₃ + H₂O

The 1-5 diketones of the type isobut, when heated with ammonia, also yield pyridine derivatives. Alkyl pyridines are also obtained by heating aldehyde ammonas alone or with aldehydes and ketones (A. v. Baeyer, Ann., 1879, 155, pp. 281, 294; J. Ploch, Ber., 1887, 20, p. 722). The subjoined table shows the chief homologues of pyridine:

PYRITES, a term applied to iron disulphide when crystallized in the cubic system, but used also in a general sense to designate a group of metallic sulphides of which this mineral is the most characteristic example. When employed as a group-name the constituent species are distinguished by prefixes: thus the type is called iron pyrites, whilst other species are known as copper pyrites, arsenical pyrites, &c. The original word pyrites (from Gr. πυρ, fire) had reference to the fact that sparks might be elicited on striking the mineral violently, as with flint, so that ὑπερτὸς κωπός meant a stone which struck fire. Hence the name seems to have been applied also to flint, and perhaps to emery and other hard stones. Nodules of pyrites have been found in prehistoric barrows and elsewhere under conditions suggesting their use as a primitive mean of producing fire. Even in late historic time it was employed in some of the old wheel-lock guns. Iron-pyrites was formerly called marcasite, a word variously written marcasin, marcasite, marchasite, marquesite, &c. The name is generally applied to distinct mineral species. The compound FeS₂ is dimorphous, and the modern practice is to distinguish the cubic forms as pyrites and the orthohombic as marcasite (q.v.). Sometimes, however, the term pyrites is loosely applied to both species, and the cubic pyrites is then differentiated by the name "pyrite"—a form which brings the last syllable into harmony with the spelling of the names of most minerals.

Iron pyrites, or pyrite, belongs crystallographically to the parallel-faced hemidrical class of the cubic system. Its common forms are serious consequence in some of the purposes to which pyrites is applied. The presence of copper, nickel and arsenic is possibly due in many cases to traces of kindred minerals, like chalcopyrite, pentlandite and mispickel.

Pyrites is a mineral of very wide distribution, occurring under varied conditions and probably originating in various ways. It is common in mineral-veins, usually associated with quartz, and is often found to occur as "mudic." It occurs commonly in cubes, in schistose and slaty rocks, and less abundantly in the younger sedimentary deposits. In coal it not infrequently forms bands and nodules known as "brasses," and may also be finely disseminated through the coal as "black pyrites"; but much of the so-called pyrites of coal is really marcasite. Films of pyrites sometimes coat the joint-planes of coal. It is believed that the bluish colour of many clays and limestones is referable to the presence of finely divided pyrites, and it is known that certain deposits of blue mud now forming around continental shores owe their colour, in part, to disseminated iron sulphide. Pyritous shales have been largely used in the manufacture of alum, and are therefore known as "alum-shales." Many fossils are mineralized with pyrites, which has evidently been reduced by the action of decomposing organic matter on a solution of iron sulphide. The iron may be less directly on ferrous carbonate dissolved in water containing carbamic acid, in the presence of certain sulphates. A similar action probably explains the origin of pyrites and marcasite in coal and lignite, in clay and shales, and in limestone like chalk.

Pyrites is largely worked for sake of the sulphur which it contains, and in many cases it has displaced brimstone in the manufacture of sulphuric acid. For this purpose its value depends on the proportion of sulphur present. Pyrites low in sulphur is incapable of sustaining its own combustion without the aid of an external source of heat, and 45% of sulphur is, for economic reasons, usually regarded as the lowest admissible for sulphuric acid manufacture. It is also important for this purpose that the ore should be as free as possible from arsenic (see SULPHURIC ACID).

An extremely important variety of pyrites is that which is more or less cupferous, and is commonly known commercially as "copper-pyrites" (q.v.), though distinct mineralogically from that mineral. It consists, indeed, mainly of iron-pyrites, with a notable but variable proportion of copper, sometimes with silver and gold, and not infrequently associated with lead and zinc sulphides. The copper probably exists as disseminated chalcopyrite. Deposits of such cupferous pyrites are widely distributed and are often of great magnitude. They are generally of lenticular form, and usually occur in or near the contact of eruptive rocks with schists or slates; the presence of the igneous rock being probably connected genetically with their origin. Among the best-known deposits of this character are those in the Huelva district, in the south-west of Spain, including the mines of Rio Tinto, Tharsis, Cañadas, &c.; with those of San Domingos in Portugal. At Rio Tinto the ore is divided into three classes: to minerals as "mudic." (1) The poorest, containing an average of about 14% of copper, which is treated locally by leaching with water and liquor containing ferric sulphate, whereby the copper is dissolved out and afterwards precipitated by pig-iron, whilst the residue is exported as ordinary iron pyrites. (2) The next contains from 2 to 5% of copper, in which the sulphur, copper and precious metals are utilized, and the residual iron oxide is then sold as "pure ore" for use in iron manufacture. (3) The cupferous ore, which averages about 6% of copper, and is treated metallurgically as described under COPPER.

The world's annual production of iron-pyrites is about 1,000,000 tons, of which production is Spain with upwards of 350,000 tons, including the cupferous pyrites. France yields about 300,000 tons, largely from the Sain Bel mines, department of the Rhône. Then follows Portugal, with its important output of cupferous pyrites. In the United States the production of pyrites now reaches more than 200,000 tons per annum. The state of Virginia is the chief producer, followed successively by Georgia, North Carolina, Colorado, Massachusetts, California, Missouri, New York, &c. From Indiana and
Ohio a quantity of pyrites is obtained as a by-product in coalmining. Newfoundland yields copious pyrites, worked at Filley's Island, whilst the nickeliferous pyrites of Sudbury in Ontario is partly magnetic (see Pyrrhotite). Magnetic pyrites of commercial importance occurs also in Virginia and Tennessee. The United Kingdom yields but little pyrites, the annual output being not more than about 10,000 tons. Large quantities of "sulphur ore" were, however, formerly worked in the Vale of Avoca, Co. Wicklow, Ireland. Finely crystallized specimens of pyrite are obtained from many other localities, especially from Cornwall, Elba and Traversella, near Ivrea, in Piedmont.

PYRITZ, a town in Germany, in the Prussian province of Pomerania, 16 m. S.W. of Stargard by the railway to Čučírn. Pop. (1905), 8600. It is still surrounded by walls with towers, and has two Evangelical churches. There are small manufactures of machinery, bricks and sugar. Excellent wheat is grown in this vicinage, while another industry is the breeding of cattle. Near the town is a fountain, which is used in the spring in which Otto, bishop of Bamberg, baptized the first Pomeranian converts to Christianity in 1124. Pyritz became a town in 1150.

PYROCATHECIN, or PYROCAThENOL, ortho-dioxybenzene, C₆H₄(OH)₂, first prepared in 1839 by H. Reinsch on distilling catechin (the juice of Mimosa catecha); occurs free in kino and in beechwood tar; its sulphonic acid is present in the urine of the horse and man. It results in the alkaline fusion of many resins, and may be prepared by fusing ortho-phenoxy-phosphonic acid, o-chlorophenol, o-bromophenol, and o-phenoldisulphonic acid with potash, or, better, by heating its methyl ether, guaiacol, C₆H₄(OH)(OCH₃), a constituent of beechwood tar, with hydrochloric acid.

Pyrocatechol crystallizes in white rhombic prisms, which melt at 104° and boils at 245°; it is readily soluble in water, alcohol and ether. Ferric chloride gives a green coloration with the aqueous solution, whilst the alkaline solution rapidly changes to a green and finally to a black colour. When exposed to the air, it readily reduces silver solutions in the cold and alkaline copper on heating.

Guaiacol may be obtained directly from beechwood tar, from pyrocatechol by methylation with potash and potassium methyl sulphonate, and from guaiacol by dehydration with phosphorus pentachloride, or by forming with ortho-nitroanisole to amino-anisol, which is then diazotized and boiled with water. It melts at 28° and boils at 250°. It is employed in medicine as an expectorant. The dimethyl ether or veratrol is also used in medicine. Depest, J. A. Phillips; read by H. L. Bouve (1890). For chemical means of distinguishing pyrite from marcasite consult H. N. Stokes, "On Pyrite and Marcasite," Bull. U. S. Geol. Surv. No. 186 (1901).

PYROLUSITE, a mineral consisting essentially of manganese dioxide (MnO₂), of importance as an ore of manganese. It is a soft, black, amorphous mineral, often with a granular, fibrous or columnar structure, and sometimes forming reniform crusts. It has a metallic lustre, and a black or bluish-black streak, and readily soils the fingers. The specific gravity is about 4.8.

Supposed crystals of pyrolusite have been proved to be pseudo-morphs after manganite; in fact the mineral often results by the dehydration and oxidation of manganite (MnO₂·H₂O), and for this reason is frequently found together with small impurities of manganese dioxide referred to the rare species polianite; they are tetragonal and isomorphous with cassiterite. Pyrolusite is an alteration product of other manganese minerals—manganite, rhodonite, and pyritohedron, and nodules in the residual clayey materials resulting from the decomposition of various rocks, for example, limestone. That it is readily deposited from solution is shown by the frequent occurrence of black dendritic markings in the crevices of rocks. Excellent specimens of which are seen in mocha stone (q.v.) and in the lithographic stone of Solenhofen in Bavaria. It is deposited from the waters of some springs, and manganiferous nodules are dredged from the floor of the deep sea.

As an ore it is extensively mined at Ilmenau and several other places in Thuringia, at Vorderhermsdorf near Prossnitz in Moravia, Platen in Bohemia, in North Wales, at several places in the United States (Vermont, Virginia, Arkansas, &c.), Nova Scotia and New Brunswick, and Chile. Pyrolusite, manganese, and hercynite, or the ore of manganiferous cherts, or in the vicinity of Potosi, in the Potosi province of Bolivia, has various economic applications. It is extensively used for the manufacture of spiegelselen and ferromanganese, and of various alloys, such as manganese-bronze. As an oxidizing agent it is extensively employed in the manufacture of certain ferro-alloys, as soda ash, and for the preparation of manganese dioxide (permanganates), and for decolorizing glass: when mixed with molten glass it oxidizes the ferrous iron to ferric iron, and so discharges the green and brown tints, hence the name pyrolusite, from Gr. πυρολύσις (fire) and λύσις (to wash). As a colouring material it is used in calico printing and dyeing; for imparting violet, amber and black colours to glass, pottery and bricks; and in the manufacture of green and violet paints. (L. J. S.)

PYROMETER (Gr. πύριμ, fire, μέτρον, a measure), an instrument for measuring high temperatures. The term was first used by Muschenbroek to denote an instrument wherein the expansion of a metal is used as a measure of the temperature. Discontinuous thermometers, depending on the expansion of a metal or salt, are also employed. Prinsep prepared a series of alloys of silver and gold, and of gold and platinum, whose melting points, as determined by accurate instruments, covered a range of temperature from 954° to 1775°, at intervals of from 25° to 30°. By placing ingots in a furnace and observing which one melted a fair idea of the temperature was obtained. Carnelley and Williams employed certain salts of known melting point; whilst the Seger's cones, employed in porcelain manufacture, depend on the fusion of small cones made of clay. (See Thermometry for scientific forms.)

PYROMORPHITE, a mineral species composed of lead chlorophosphate (PbCl)₃(PbO)₃, sometimes occurring in sufficient abundance to be mined as an ore of lead. Crystals are common, and have the form of a hexagonal prism terminated by the three planes, sometimes combined with narrow faces of a hexagonal pyramid. Crystals with a barrel-like curvature are not uncommon. Globular and reniform masses are also found. As proved by the etched figures on the faces, crystals possess the same cleavage as a parallel cleavage and the mineral was named pyromorphite and also mimetite are isomorphous. Between pyromorphite and the corresponding chloro-arsenate (mimetite, q.v.) the resemblance in external characters is so close that, as a rule, it is impossible to distinguish between them by chemical tests: and they were formerly confused under the names "green lead ore" and "brown lead ore" (German, Grünkiesler and Braunkiesler). The phosphite was first distinguished chemically by M. H. Klaproth, in 1784, and it was named pyromorphite by J. F. L. Haußmann in 1813, being so named from the Gr. πύριμ (fire) and μέτρον (form), because when a fragment of the mineral is fused the globule assumes a faceted form on solidifying. The colour of the mineral is usually green, but sometimes brown, and the lustre is resinous. The hardness is 3½ and the specific gravity 6.5-7.1. Owing to isomorphous replacement of the phosphorus by arsenic there may be a gradual passage from pyromorphite to mimetite. Varieties are distinguished by their combination with hydroxylammonium as does the isomeric phosphoglaucin which yields a trioxide (see Polythymelines). Pyrogallic dimethyl ether is found in beechwood tar. Pyrogallic has antiseptic properties and is employed medicinally in the treatment of psoriasis, Eugallol, or monacetate pyrogallic and lenigall, or triacetate pyrogallic, are also used.

PYRITZ—PYROMORPHITE
PYRONES

Pyromorphite has resulted from the alteration of galena in the oxidized portions of metalliferous veins, and is frequently met with in the upper levels of lead mines. Finely crystallized specimens have been found at Braubach and Rams in Nassau, Wheal Alfred in Cornwall, and Coll in Cumberland. Lead-ants are extensively worked in Pennsylvania, Huelgoat in Finistere, Brittany, &c. At the last-named locality, as well as at Wheal Hope, near Truro in Cornwall, there were formerly found curious pseudomorphs of galena after pyromorphite, known as "blue lead ore." (L. J. S.)

PYRONES, in chemistry, a group of heterocyclic compounds, containing a six-membered ring composed of five carbon atoms and one oxygen atom. Two types are known, namely, the α-pyrones, which may be regarded as the lactones of δ-oxo-diolefin carboxylic acids, and the γ-pyrones, which may be regarded as anhydrides of diolefinic dicarboxylic acids:

\[
\text{α-Pyrone:} \quad \text{CH}_2\text{CO} - \text{CH} = \text{C} - \text{CH}_2\text{CO}
\]

\[
\text{γ-Pyrone:} \quad \text{CH}_2\text{CO} - \text{CH} = \text{C} - \text{CH}_2\text{CO}
\]

As a class, the pyrones are rather unstable compounds, the ring being readily broken. When digested with ammonia, the oxygen atom is replaced by the imino (NH) group, and pyridones or oxypyrrols are formed.

γ-Pyrones.—The comical compounds belong to this series, and were first obtained by A. Hantsch in 1884 (Ann. 222, p. 1) and H. v. Pechmann (Ann., 1884, 17, p. 396).

α-Pyrone or coumarin, C₆H₅O₃, is obtained by distilling the mercury salt of coumaric acid (from malic acid and sulphuric acid) in a current of hydrogen. It is an oily liquid which boils at 206–209° C., and with alkalis it forms permalonic acid, HOC-C=CH₂-C=O-H₂O. α-Dimethyl-α-pyrone or mesitene lactone, C₈H₇O₃, is obtained from iso-dehydrasec acid (from aceto-acetic ester and sulphuric acid).

Phenoxycoumarin or α-phenyl-α-pyrone, C₆H₅C=CH₂-C=O, is found in coto-bark. When heated with alkalis it yields benzoic acid and acetophenone; reduction by hydrosulphite gives k-phenyl valeric acid, and when heated with ammonium acetate and ammonia it yields phenylpyridine. This produces an additional product with phenol in which aniline; the latter gives diphenylhydramine when boiled with concentrated hydrochloric acid. Paracoumarin, C₆H₅O₃, which also occurs in coto-bark, appears to be a bisoxymethylene phenylpyryidine, C₆H₅O₂C=CH₂-C=O.

Various pyrones (keto-dihydropyrones) derived from the compound having formula I. (below) are known, the most important of which is dehydracetic acid, C₆H₄O₃, first obtained by Geuther (Jena’sche Zeit., 1866, p. 8). It may be prepared by distilling aceto-acetic anhydride with water, or by boiling aceto-acetic acid with sodium in acetic acid, or by heating acetyl chloride with pyridine to 200–220° C. J. N. Collie regards it as having formula II., whilst Feist (Ann. 1890, 257, p. 253) favours formula III.

\[
\text{OC-CH}_2\text{CH-CH}-\text{CH}_2\text{CO} \quad \text{OC-CH}_2\text{CH-CH}_2\text{CO} \quad \text{OC-CH}_2\text{CH}_2\text{CO}
\]

(1) (II) (III)

It crystallizes in plates which melt at 108–109° C. and is a weak alcoholic potash converts it into aceto-acetic ester, and with concentrated aqueous caustic potash it is completely decomposed into acetic acid, and carbon monoxide.

γ-Pyrones.—Many of these compounds are found as naturally occurring substances: thus chelidonic acid is found in Chelidonium majus and meconic acid in opium, and the more complex flavone and flavonol derivatives are also found in various plants. The γ-pyrones may be synthesized by eliminating water from the 1,3,5-triketones:

\[
\text{OC-CH}_2\text{CO-CO-R} \quad \text{OC-CH}_2\text{CO-CO-R}
\]

Acetone dioxalic ester. → Chelidonic acid

γ-Pyrones are but slowly decomposed by H₂SO₄, melts 32° C. and boiling at 210–215° C. is obtained by eliminating carbon dioxide from chelidonic acid (obtained as above), or from comice acid, obtained by heating chelidonic acid. α-Dimethyl-γ-pyrone, C₆H₄(C=O), is obtained by the action of hydrosulphite on the ester of the corresponding acid (Feist, Ann. 1890, 257, p. 272); by the action of carbonyl chloride on the copper derivative of acetoacetic ester, and by the action of concentrated hydrochloric acid on dehydroacetic acid. It forms a yellow salt which with oxalic acid yields diacetyacetone. The most striking property of this compound is that it forms salts with mineral acids (J. N. Collie and Tickle, Journ. Chem. Soc., 1869, p. 710). For example, hydrochloric acid adds on at the oxygen atom, and the salts so formed are relatively unstable and undergo complete hydrolysis in dilute aqueous solution. The oxygen atom is probably tetravalent, and the salts are to be regarded as oxonium salts (see OXOGEN). Collie (Journ. Chem. Soc., 1904, 85, p. 971) is of the opinion that both oxygen atoms are to be regarded as tetravalent in these salts and gives the second formula below for the molecule.

\[
\text{HC-CHO} \quad \text{HC-CHO}
\]

Meconic acid, or oxyxpyrone tricarboxylic acid (3–6)

C₆H₄(OH)(C=O)₃, found in opium, crystallizes in prisms and gives a characteristic deep red colour with ferric chloride. On heating to 200° it gives conic acid, C₆H₄(OH)(C=O)H, and on distillation pyromonoeic acid or β-oxyxpyrone. On conic acid see A. Peratoner, Chem., 1906, 36, p. 1.

The tetrahydro-γ-pyrones may be obtained by the condensation of aldehydes with acetone-dicarboxylic ester in the presence of hydrochloric acid.

Benzopyrones.

Compounds of this type are known in both the α and γ series, the former including the coumarins (γ. p.) and isocoumarins, and the latter a number of naturally occurring dyestuffs which may be considered as derivatives of flavone (see under).

Isocoumarins (annexed formula) may be prepared by the action of acid chlorides or anhydrides on ortho-xanthylbenzoyl cyanide (B., 1892, 25, p. 3563), by the molecular rearrangement of the benzal and alkylidene phthalides (G. Gabriel, Ann., 1885, 18, p. 2443; 1887, 20, p. 2365), and by the action of malonic anhydride and hydrochloric acid on β-naphthoquinone.

Benzophenone. — The parent substance of the γ-series, namely, benzophenone (chromone), was obtained in 1895 by S. Rothemund (Journ. de Chem. Soc., 1895, 77, p. 1179). Isocoumarin is obtained by heating its carboxylic acid (formed by the action of concentrated sulphuric acid on phenoxyxanthic acid) in vacuo. It crystallizes in colourless needles, and its solution in acetone contains the phenoxyxanthic anion. Benzophenone is the naturally occurring compounds, chrysirin, galbanin, quercetin, apigenine, etc., are considered to be derivatives of flavone (or flavonol), which is a phenyl-2-benz-γ-pyrene (S. Kostanecki, Ber., 1878, 11, p. 1258). Flavone flavonol, flavanone flavanone flavonol, flavone flavonol.

Flavone, C₆H₄(OH), is obtained by the action of potassium hydroxide on the acetyl derivative of benzylidene-ortho-xyloacetone. It forms a yellow crystalline product which dissolves in concentrated sulphuric acid with a yellow colour and shows a faint blue fluorescence. On fusion with caustic alkalis it yields salicylic acid, acetophenone, ortho-oxyacetophenone and benzoic acid, the latter two products being also formed by hydrolysis with alcoholic potash. Chrom. has been obtained by distilling a mixture of chrysirin, C₂H₂O₂C=CH₂O₂C=O, C₂H₂O₄, with sodium in acetic acid, or by heating it with acetyl chloride. C₅H₄O₅, is a yellow dye, which may be obtained from the barks of various varieties of illumin. On hydrolysis it yields phloroglucin and benzoic and acetic acids. It has been synthesized by heating trimethoxy benzyl acetophenone (obtained from the hydrolysis of 2-methyl-1,3-dimethoxyacetophenone) with hydrochloric acid, and also by the action of hydrochloric acid on 2,4-dibrom-1,3-dimethoxyacetophenone. Galbanin or α'-trihydroxyflavone, C₂H₂O₄, crystallizes in yellow needles. It has been synthesized by heating trimethoxy benzyl acetophenone (obtained from the hydrolysis of 2-methyl-1,3-dimethoxyacetophenone) with hydrochloric acid, and also by the action of hydrochloric acid on 2,4-dibrom-1,3-dimethoxyacetophenone. Galbanin or α'-trihydroxyflavone, C₂H₂O₄, crystallizes in yellow needles. It has been synthesized by heating trimethoxy benzyl acetophenone (obtained from the hydrolysis of 2-methyl-1,3-dimethoxyacetophenone) with hydrochloric acid, and also by the action of hydrochloric acid on 2,4-dibrom-1,3-dimethoxyacetophenone. Galbanin or α'-trihydroxyflavone, C₂H₂O₄, crystallizes in yellow needles. It has been synthesized by heating trimethoxy benzyl acetophenone (obtained from the hydrolysis of 2-methyl-1,3-dimethoxyacetophenone) with hydrochloric acid, and also by the action of hydrochloric acid on 2,4-dibrom-1,3-dimethoxyacetophenone. Galbanin or α'-trihydroxyflavone, C₂H₂O₄, crystallizes in yellow needles.
yellow colour and blue fluorescence. Fisetin or 3-3'4-tetraydroxyflavonol, \( C_{6}H_{12}O_{5} \) occurs in the wood of Quercus colorado, and can be obtained by heating with dilute acids. It crystallizes in pale yellow needles. In dilute alcoholic solutions it shows a dark green fluorescence. On treatment with ethanol it shows a red fluorescence and a red solution and a red precipitate of the phenolic acid is formed. It is obtained synthetically from 2-0xy-3,4-dimethoxy-4-ethoxy-chalcone. For the various stages in this synthesis see below, since the method employed is applicable to other members of the group.

\]

This structure of the fasicin molecule was confirmed by Herzeg (Monatsh., 1891, 12, p. 177), who showed that the tetrabor ethyl of fasicin on hydrolysis with a dilute alcohol gives dihydroxypro- 

catechol and dihydroxybenzoic acid, the latter on oxidation yielding catechol and dihydroxybenzoic acid. Quercetin or 3-3'4-tetraydroxyflavonol, \( C_{6}H_{12}O_{5} \) has been found in the wdc obtained from Reseda luteola. It crystallizes in small yellow needles, which dissolve in solutions of alkali. Of fasicin and gorsein, in alcoholic solutions, the yellowish caustic alkali it yields phloroglucin and protocatechic acid. It is obtained synthetically from 1-3-2'4-tetraydroxyflavonan by bromination, the tribromo-compound being decomposed by the successive action of dilute potash and concentrated hydrochloric acid. Quercetin or 3-3'4-tetraydroxyflavonol, \( C_{6}H_{12}O_{5} \) is a decomposition product of quercetin ring, and is found in many plants. It is obtained by the hydrosylysis of quercetin with dilute sulphuric acid. It is a pale yellow crystalline powder. Alcohol hydrolysis to protocatechic acid and phloroglucin. It is prepared synthetically from 2-0xy-3,4'-6'-tetraydroxy- 

chalcone. Rhamnatin, \( C_{6}H_{12}O_{5} \) is the monomethyl ether, is a pale yellow powder. Rhamnit, \( C_{6}H_{12}O_{5} \) is the dimethyl ether, crystallizes in yellow needles. Quercetin or 3-3'4-tetraydroxyflavonol, \( C_{6}H_{12}O_{5} \) occurs in the wood of Autoseris integrifolius, and crystallizes in yellow long needles, which on fusion with caustic alkali decomposes into phloroglucin, resinoid and oxalic acid. On reduction with sodium amalgam in alcoholic solutions it yields phloroglucin and \( CH_{2}OH \) as the yellowish-acid. It has a tetrabor ethyl and a penta-acetate. It has been synthesized from 1-3-2'4-tetraydroxyflavonan by converting this into its isonitroso compound, which on reduction with sodium gives a yellow needle. Myricetin or 1-3-2'4-5'-penta-oxy flavonol, \( C_{6}H_{12}O_{5} \) is found in the wood of Myrica

\]

The parent substance of the group, namely chroman (annexed formula), was obtained by J. v. Braun and A. Scindorff in 1905 (Ber., 38, p. 850) by diazotizing the ortho-aromatic chlorohydrin and heating the resulting chlorophenol with a caustic alkali. It is a colourless oil which boils at 214-215 °C. and possesses a characteristic peppermint odour.

For the dibenzo-pyrones see XANTHONE.

**PYROPE** (pronounced prip), a deep red variety of garnet, named from the Gr. \( \pi\rho\i\o\rho\i\o\rho\i\o\rho\i\o\rho\i\o\rho \) (fiery) in allusion to its colour. It is used, like almandine (q.v.), as a gem-stone, but may be distinguished by the absence of any tinge of violet in its colour and by its lower specific gravity (3.7 to 3.9), while of almandine is 4.1 to 4.3). The typical colour of pyrope is blood-red, though sometimes a trace of orange gives rise to a hæmatine hue: occasionally the mineral becomes nearly black, as seen in the pyrope of Arendal in Norway. Crystals are rare, but cubic forms have been observed. Pyrope may be regarded as a magnesium-aluminium garnet (see GARNET), but it usually contains more or less calcium, iron, manganese and chromism, and the rich colour of the mineral seems due to the presence of some of the last three metals, though their exact condition in the mineral has not been determined.

Pyrope generally occurs in grains embedded in peridotites (olivine rocks) or in serpentines resulting from their alteration, or it is found as loose grains in detritus due to the disintegration of the matrix. The grains may be surrounded by a chloritic ring, or by a crust of a fibrous mineral called by A. Schraul kelyphite (from the Gr. \( \kappa\u03b3\u03b1\u03b5\u03b5\u03be\u03b9\ )) a nut-shell, which seems in some cases to be an amphibole. In the Mount Cenis, in the Cottian Alps, and in the Saxon gabbros, found loose in gravels, were referred to by G. Arscoropis as far back as 1546. Several localities in Bohemia are famous for its occurrence. It is usually a gemstone of great value, in France, in Saxon and in the Saxon garnets, found loose in gravels, were referred to by G. Arscoropis as far back as 1546. Several localities in Bohemia are famous for its occurrence. It is usually a gemstone of great value, in France, in Saxon and

...
slicate. The compact variety of pyrophyllite is used for slate pencils and tailors’ chalk (“French chalk”), and is carved by the Chinese into small images and ornaments of various kinds. Other soft compact minerals (steatite and pinte) are used for these Chinese carvings are included with pyrophyllite under the terms agatolamite and pagonite.

Pyrophyllite occurs in schistose rocks, often associated with cyanite, of which it is an alteration product. Pale green foliated masses are very likable in appearance and are used at Beresowsk near Ekaternburg in the Ural, and at Zermatt in Switzerland. The most extensive deposits are in the Deep river region of North Carolina, where the compact variety is mined, and in South Carolina and Georgia.

PYROXENE, an important group of rock-forming minerals, very similar in chemical composition and general characters to the amphiboles (q.v.). Although crystallizing in three different systems, they all possess distinct prismatic cleavages, the angles between which are about 85° (the cleavage angle in the amphiboles being 56°). They are metastasicates but, as shown in the following table, the composition varies widely in the different species, with corresponding differences in the various physical characters. The name pyroxene was originally given by R. J. Haüy in 1786 to the black crystals of augite found in the lavas of Vesuvius and Etna: he derived the name from the Greek πυρόξενον (fire) and ξενος (a stranger), because he thought that the crystals had been accidentally caught up by the lavas which contained them. As a matter of fact, the pyroxenes are, next to the felspars, the commonest constituents of igneous rocks of almost all kinds, being especially characteristic of those of basic composition. An igneous rock composed almost wholly of pyroxene is known as a pyroxenite. Besides being mineral of primary origin in igneous rocks, the pyroxenes are also of frequent occurrence in metamorphic rocks, for example, in crystalline limestones, being then of secondary origin.

At the present day the name pyroxene is used as a group name for all the minerals enumerated below, though sometimes it is also applied as a specific name to include the monoclinic members diopside, hedenbergite, scherffelite and augite.

For details respecting the special characters and modes of occurrence of most of these species reference may be made to the respective articles under the names of the minerals. Hedenbergite, or calcium iron pyroxene, is a black mineral closely allied to diopside (q.v.) and, owing to the isomorphous replacement of iron by magnesium, there is no sharp line of division between them. Scherffelite, a magnesium minette, is a brown mineral found in the manganese deposits of Sweden. Pectolite is a secondary mineral occurring as white masses with a radially fibrous structure in the veins and cavities of basic igneous rocks. Babingtonite is found as small black crystals on felspar in the granite of Bavens in France, and in the Haytor iron ore deposit in England. Roseneubirite, hoirotahite, and some other rare members containing zirconium and fluorspar, occur as accessory constituents in the nepheline syenite of southern Norway.

PYROXENITE, a rock consisting essentially of minerals of the pyroxene group, such as augite and diatite, hypersthene, bronzite or enstatite. Names have been given to members of this group according to their component minerals, e.g., pyroxyenite (augite), diatite (diatite), hypersthene (hypersthene), bronzites (bronzite), websterite (diallage and hypersthene). Closely allied to this group are the hornblendes, consisting essentially of hornblende. The term perkinsite (Gr. περίκυθος, dark) has also been used to designate the whole series.

They are essentially of igneous origin, though some pyroxenites are included in the metamorphic complex of the Lewishian of Scotland; those pyroxene rocks which result from the contact alteration of impure limestones are described as pyroxene hornfelses (calc-silicate hornfelses). The pyroxenites are closely allied to the gabbros and norites, from which they differ by the absence of felspar, and to the peridotites, which are distinguished from them by containing olivine. This connexion is indicated also by their common occurrence in the same rocks as the gabbros and peridotites and seldom are found by themselves. They are strictly plutonic and often very coarse-grained, containing individual crystals which may be several inches in length. The principal accessory minerals, in addition to olivine and felspar, are chromite and apatite, and in some cases garnet and pyrrhotite. The gabbroic and pyroxenitic rocks may contain the constituent minerals in the form of dikes or segregations in gabbro and peridotite, e.g. in Shetland, and in the Hudson river, New York, and in Saxony. The composition of these rocks may often have a close resemblance to those of the surrounding rock. By decomposition the rocks consisting of pyroxene pass into serpentines, which sometimes preserve the original structures of the primary minerals, such as the lamination of hypersthene and the rectangular cleavage of augite. Under pressure-metamorphism hornblende is developed and various types of amphibolite and hornblende-schist are produced. Occasionally rocks rich in pyroxene are found as basic facies of nepheline syenites, the good example being provided by the melanite syenites associated with boroninite (q.v.) at Ledbeg in Sutherlandshire.

PYRRHOTITE, a mineral species consisting of iron sulphide and crystallizing in the hexagonal system. The formula is Fe₅S₈, n, where n may vary from 5 to 16; usually it is Fe₅S₈ or Fe₆S₈, the latter being also the composition of the artificially prepared compound. Small amounts of nickel and cobalt are often present.
PYRRHUS—PYRROL

697

PYRRHUS (c. 318–272 B.C.), king of Epirus, son of Aeacides, and a member of the royal family of the Molossians. He claimed descent from Pyrrhus, the son of Achilles, and was also connected with the royal family of Macedonia through Olympias, the mother of Alexander the Great. When a mere lad he became king of the wild mountain tribes of Epirus, and learned the art of war in the school of Demetrius Poliorcetes and his father Antigonus. He fought by their side at the battle of Ipsus (301) in Phrygia, in which they were decisively defeated by the combined armies of Seleucus Nicator and Lysimachus. Soon afterwards he was sent to the court of Ptolemy of Egypt at Alexandria as a pledge for the faithful carrying out of an agreement of alliance between his brother-in-law Demetrius and Ptolemy. Through Ptolemy, whose step-daughter Antigone he married, Pyrrhus was enabled to establish himself firmly on the throne of Epirus, and became a formidable opponent to Demetrius, who was now king of Macedonia and the leading man in the Greek world. He defeated one of Demetrius’ generals in Aetolia, invaded Macedonia, and forced Demetrius to conclude a truce with him. For about seven months Pyrrhus was in possession of a large part of Macedonia, Demetrius finding it convenient to make this surrender on condition that Pyrrhus did not meddle with the affairs of Peloponnesus. But in 286 he was defeated by Lysimachus at Edessa, driven out of Macedonia, and compelled to fall back on his little kingdom of Epirus. In 281 came the great opportunity of his life. An embassy was sent to him from the Greek city Tarentum in southern Italy with a request for aid against Rome, whose hostility the Tarentines had recklessly provoked. After some hesitation on the part of the Tarentines, Pyrrhus’ conditions were accepted, and he crossed over to Italy with a force of 15,000 men and a body of troops and occupied the city. Pyrrhus soon followed with a miscellaneous force of about 25,000 men (partly furnished by Ptolemy Cænarchus of Macedonia) and some elephants. The Tarentines and Italian Greeks shrank, however, from anything like serious effort, and resented his calling upon them for men and money. Rome meantime levied a special war contribution, called on her subjects and allies for their full contingent of troops, and posted strong garrisons in all towns of doubtful fidelity. She was now the dominant power in Italy, but her position was critical, as in the north she had had trouble with the Etruscans and the Gauls, while in the south the Lucanians and the Bruttians were making common cause with Tarentum and the Greek cities. For the first time in history Greeks and Romans met in battle at Heraclia near the shores of the Gulf of Tarentum, and the cavalry and elephants of Pyrrhus secured for him a complete victory over the combined armies of Italy. The Laevus, though at a disadvantage, could not withstand the might of the battle. The victory was not finally achieved, however, and Pyrrhus was compelled to retire upon Epirus (February 279). He returned to Tarentum with a large body of troops, and occupied the city. Pyrrhus now had the Samnites as well as the Lucanians and the Bruttians and all the Greek cities of southern Italy with him, he found every city closed against him as he advanced in Rome through Latium. The peace negotiations, carried on by the skilful diplomatist Cineas, the minister of Pyrrhus, led to no result; the senate seemed inclined to come to terms, but the fiery and patriotic eloquence of the aged and blind Appius Claudius (the censor) carried the day. Cineas was ordered to leave the city at once and to tell his master that Rome could not negotiate so long as foreign troops remained on the soil of Italy. In the second year of the war (279), Pyrrhus again defeated a Roman army at Asculum (mod. Ascoli) in Apulia, but Rome still had armies in the field and her Italian confederation was not broken up. For a while he quitted Italy for Sicily, at the invitation of the Syracusans, with the idea of making himself the head of the Sicilian Greeks and driving the Carthaginians out of the island. In his military operations he was on the whole successful; and Rome and Carthage, in face of the common danger, concluded an offensive and defensive alliance against him. He passed three years in Sicily, but offended the Greek cities, which he governed in the fashion of a despot. Finding that he could no longer hold Sicily in face of the ill feeling thus aroused, and reproached by the Sammites for having deserted them, he decided to return to Italy. On the voyage he was attacked by the Carthaginians and lost several vessels. When he reached Italy, the Tarentines and the other Greek cities, having lost confidence in him, refused to supply him with men or money. Thoroughly disheartened, he made one more effort and engaged a Roman army at Beneventum (275) in the Samnite country, but his arrangements miscarried, and he was defeated with the loss of his camp and the greater part of his army. Nothing remained but to go back to Greece. He left a garrison in Tarentum and returned the following year to his home in Epirus after a six years’ absence. The brief remainder of his life was passed in camps and battles, without any glorious result. He gained a victory on Macedonian soil over Antigonus Gonatas, king of Macedonia, whose troops hailed him as king. In 273 he was invited into Peloponnesus by Cleonymus to settle by force of arms a dispute about the royal succession at Sparta. He was defeated at Leuctra, and with great loss was forced to leave Sparta. Next, at the invitation of a political faction, he went to Argos, where, during a fight by night in the streets, he was struck on the head by a huge tile. He fell from his horse, and was put to death by one of the soldiers of Antigonus.

Pyrrhus was a brilliant and dashling soldier, but he was aptly compared to a gambler who made many good throws with the dice, but could not make proper use of them in the game. He obtained no lasting results, and was never more than a captain of mercenaries, yet there was something chivalrous about him which seems to have made him a general favourite. After his death Macedonia had, for a time at least, nothing to fear, and the liberty of Greece was quite in the sphere of that power. Pyrrhus wrote a history of the art of war, which is praised by Cicero, and quoted by Dionysius of Halicarnassus and Plutarch.

The chief ancient authority for the life of Pyrrhus is Flutarch; see also Polybius xvii. 11, and elsewhere; Dion. Halic. xviii. 1, 6. 9; Pausanias i. 13; Justin xiii. 1, 2, xxiii. 3, xxv. 4. 5; Modern monographs by G. F. Hertzberg, ' ROM and König Pyrrhus (popular); in O. Jager’s Darstellungen aus der römischen Geschichte, 1870); R. von Scala, Der Pyrrhische Krieg (1884), with map of Roman garrison system in 281; R. Schubert, Geschichte des Pyrrhus (1894), with full list of authorities; also Rome: History, 'The Republic.'
PYRUVIC ACID—PYTHAGORAS

Dilute acid, ammonia is evolved, and an amorphous powder of variable composition, known as pyrrol-rod, separates out. The pyrrolic ring is easily broken, e.g., hydroxylamine gives the dioxime of succinic aldehyde. Pyrrole is readily converted into pyrrole derivatives by acting with bromoform, chloroform, or methylene iodide on its potassium salt, β-brom- and β-chloro-pyrrole being obtained with the first two compounds, and pyrrole itself with the last. Iodine in alkaline solution converts pyrrole into iodol (tetra-iodopyrrole), crystallizing in yellowish-brown needles, which decompose on heating. It may also be prepared by heating tetra-brom- or tetra-chloropyrrole with potassium iodide in alcoholic solution (German patent, 38423, 1886).

It is used as an antiseptic.

Zinc dust and hydrochloric acid reduce pyrrole to pyrrolidine (dihydropyrole), C₅H₅NH, a liquid which boils at 86° C. It is soluble in water and has strongly basic properties and an alkaline reaction. Hydriodic acid at high temperatures reduces pyrrole to pyrrolidine (tetra-hydropsyrole), C₅H₅NH₂. Pyrrolidine has also been prepared by A. Thiele (Ber., 1895, 38, p. 4154) from β-ox-propionic aldehyde diethyl acetate. The chlorine atom of this compound is replaced by the cyano-group, which is then reduced to the CH₃NH₂ group and coupled up with benzene sulphonic acid to form the compound C₆H₅SO₂NH(C₅H₅)CH₂CH₂OCONH₂. This compound is readily split out into alcohol, and on the ring compound then formed yields pyrrolidine on reduction by sodium in amyl alcohol solution. An α-pyrrolidine carboxylic acid and its hydroxyster derivatives have been detected by E. Fischer among the products of hydrolysis of protein pyrrol. R. Weizel, (J. prakt. Chem., 103, p. 1154) obtained this acid by the action of a methyl solution of ammonia on dibrompropylmalonic ester at 140° C. The disodium salt being then hydrolysed either by hydrochloric acid or baryta water:

\[ 	ext{CH₂CBr(CO₂H)₂} + 	ext{CH₂CONH₂} + 	ext{NH₂OH} \rightarrow 
\text{CH₂CH₂(CO₂H)} + 
\text{CH₂CH₂NH₂} + 
\text{CH₂CO₂H} \]

Numerous substitution derivatives of pyrrole are known. The N-derivatives are prepared by the action of alky halides and acid chlorides on potassium pyrrole. C-derivatives have been prepared in various ways. L. Knorr, by the action of ammonia on aceto-acetic ester, obtained β-imidobutyric ester, which with nitric acid yields α-isolactone-β-imidobutyric ester, C₅H₅C(NH₂)-C(N-OH)-CO₂CH₃. Reduction of this ester leads to the formation of ammonia, hydroxylamine, and dimethyl pyrrole dicarboxylic ester,

\[ 	ext{HNC}_3\text{C(CO₂H)}_2 + \text{H₂C₂O} \rightarrow 
\text{CH₃CO}_3\text{C(CO₂H)}_2 \]

He also found that diaceto succinic ester reacts with compounds of the type NH₄R (R = H, CH₃, OH, NH₄H₂ &c.) to form pyrrole derivatives:

\[ 
\text{CH}_3\text{CO}_2\text{CH}_2\text{CO}_2\text{H} + 
\text{NH}_3 \rightarrow 
\text{CH}_3\text{CO}_2\text{CH}_2\text{CO}_2\text{H} + 
\text{CH}_3\text{CO}_2\text{CH}_2\text{CO}_2\text{H} \]

By using compounds of the type NH₄R and acetoepheno aceto-acetic ester CH₃CO₂CH₂CO₂CH₂CO₂H, R. Paal obtained similar results. For the benzo-pyroles see IODE.

PYRUVIC ACID, or PYRORACEMIC ACID, CH₃CO₂CO₂H, an organic acid first obtained by J. Berzelius by the dry distillation of tartaric or racemic acids (Pogg. Ann., 1835, 36, p. 1). It may be prepared by boiling a dichlopropionic acid with silver oxide; by the hydrolysis of acetyl cyanide with hydrochloric acid (J. Claisen and J. Shadwell, Ber., 1878, 11, pp. 620, 1563), and by warming oxalacetic acid with a 10% solution of sulphuric acid. It is a white, almost tasteless, distilling acid. The hydrochloride with a base (preferably potassium carbonate) at about 100–200° C., the crude product being afterwards fractionated. It is a liquid which boils at about 165° C. (with partial decomposition); it may be solidified, and when pure melts at 13-6° C. (L. Simon Bull. Soc. Chim., 1805 [3], 13, p. 335). It is readily soluble in water, alcohol and ether. It reduces ammoniacal silver solutions. When heated with hydrochloric acid to 100° C. it yields carbon dioxide and pyrotratic acid, C₆H₃O₂, and when warmed with dilute sulphuric acid to 150° C. it gives carbon dioxide and acetaldehyde. Sodium amalgam or zinc and hydrochloric acid reduce it to lactic acid, whilst hydroiodic acid gives propionic acid. It readily condenses with aromatic hydrocarbons in the presence of sulphuric acid. It is somewhat readily oxidized; nitric acid gives carbonic and oxalic acids, and chromic acid, carbolic and acetic acids. It forms a well-crystallized hydrate with phenylhydrazine; and a-nitro propionic acid with hydroxylamine. It is monobasic and yields salts which only crystallize with great difficulty; when liberated from these salts by a mineral acid it forms a syrupy non-volatile mass. In aqueous solution it gives a red colour with ferric chloride. It shows characteristic ketone reactions, yielding a bisulphite compound and combining with hydrocyanic acid to form the nitrile of α-oxysuccinic acid. When warmed with baryta water it gives uvic acid.

Pyruvic nitrile, or acetyl cyanide, CH₃CO-CN, may be prepared by the action of silver cyanide on acetyl chloride; or of acetyl cyanide on acetoacetic ester (L. Claisen and O. Annesser, Ber., 1887, 20, p. 2196). It is a liquid which boils at 93° C. and with caustic alkali polymerizes to diacetylcyandiacide.

PYTHAGORAS (6th century B.C.), Greek philosopher, was, in all probability, a native of Samos or one of the neighbouring islands (others say a Tyrrenian, a Syrian or a Tyrian), and the first part of his life may therefore be said to belong to that Ionian seaboard which had already witnessed the first development of philosophic thought in Greece (see IONIAN SCHOOL). The exact year of his birth has been variously placed between 566 and 569 b.c., but 562 may be taken as the most probable date. He was a pupil of Mencareus and Thadamas (Diog. Laert. VIII. 2). He left in Ionia the reputation of a learned and universally informed man. "Of all men Pythagoras, the son of Mencareus, was the most assiduous inquirer," says Heraclitus, and then proceeds in his contemptuous fashion to brand his predecessor's wisdom as only ecclesiastically compiled information or polynymy (Ἀθροισμα). This accumulated wisdom, as well as most of the tenets of the Pythagorean school, was attributed in antiquity to the extensive travels of Pythagoras, which brought him in contact (so it was said) not only with the Egyptians, the Phoenicians, the Chaldeans, the Jews and the Arabsians, but also with the Druids of Gaul, the Persian Magi and the Brahmans. But these tales represent only the tendency of a later age to connect the beginnings of Greek speculation with the hoary religions and priesthoods of the East. There is no intrinsic improbability, however, in the statement of Isocrates (Laud. Buisr. 28, p. 227 Steph.) that Pythagoras visited Egypt and other countries of the Mediterranean, for travel was one of the few ways of gathering knowledge. Some of the accounts (e.g. Callimachus) represent Pythagoras as deriving much of his mathematical knowledge from Egyptian sources; but, however, it may have been with the practical beginnings of geometrical knowledge, the scientific development of mathematical principles can be shown to be an independent product of Greek genius. Some of the rules of the Pythagorean ritual have their Egyptian parallels, as Herodotus points out, but it does not necessarily follow that they were borrowed from that quarter, and he is certainly wrong in tracing the doctrine of metempsychosis (q.v.) to Egypt.

The historically important part of his career begins with his migration to Krotona, one of the Dorian colonies in the south of Italy, about the year 529. According to tradition, he was driven from Samos by the tyranny of Polykrates. At Krotona Pythagoras speedily became the centre of a widespread and influential organization, which seems to have resembled a religious brotherhood or an association for the moral reformation of society much more than a philosophic school. Pythagoras was the centre of a religious and philosophsic, not a moral reformer than as a speculative thinker or scientific teacher; and the doctrine of the school which is most clearly traceable to Pythagoras himself in the ethico-mystical doctrine of transmigration. The Pythagorean brotherhood had its rise in the wave of religious revival which swept over Hellas in the 6th century B.C., and it had much in common with the Orphic communities which sought by rites and abstinences to purify the believer’s soul and enable it to escape from the "wheel of birth." Its aims were undoubtedly those of a religious order rather than a political league. But a private religious organization of this description had no place in the traditions of Greek life, and could only maintain itself by establishing the "rule of the saints" upon a political basis. The Pythagoreans appear to have established their supremacy for a time over a considerable part of Magna Graecia,
but this entanglement with politics led to the end of the dis-
memberment and suppression of the society. The authorities
differed hopelessly in chronology, but according to the balance of
evidence the first reaction against the Pythagoreans took place in
the lifetime of Pythagoras after the victory gained by Crotone
over Sybaris in 510. Dissensions seem to have arisen about the
allotment of the conquered territory, and an adverse party was
formed in Crotone under the leadership of Cylon. This was
probably the cause of Pythagoras’s withdrawal to Metapontum,
which an almost unanimous tradition assigns as the place of
his death in the end of the 6th or the beginning of the 5th
century. The order appears to have continued powerful in
Magna Graecia till the middle of the 5th century, when it was
violently trampled out. The meeting-houses of the Pythago-
reans were everywhere sacked and burned; mention is made in
particular of the house of Milo in Crotone, where fifty or
sixty leading Pythagoreans were surprised and slain.

The persecution to which the brotherhood was subjected
throughout Magna Graecia was the immediate cause of the
spread of the Pythagorean philosophy in Greece proper.
Philo-
laus, who resided at Thebes in the end of the 5th century (cf.
Plato, Phaedo, 61 D), was the author of the first written exis-
tion of the system. Lysis, the instructor of Epaminondas, was
another of these refugees. This Theban Pythagoreanism had
an important influence upon Plato’s thought, and Philolaus
had also disciples in the stricter sense. But as a philosophic
school Pythagoreanism became extinct in Greece about the
middle of the 4th century. In Italy—where, after a temporary
suppression, it attained a new importance in the person of
Archytas of Tarentum—the school finally disappeared about the
same time.

Aristotle in his accounts of Pythagorean doctrines never refers
to Pythagoras but always with a studied vagueness to “the Pyth-
agoreans” (οἱ πυθαγόρειοι). Nevertheless, certain doctrines
can be traced to the founder’s teaching. Foremost among these
is the doctrine of transmigration (see Metempsychosis). Pythagoreans’s teaching on this point is
connected by one of the most trustworthy authorities with the
document of the kinship of all living beings; and in the light of anthropo-polyvalent research is easy to recognize the close relation
ship of the two beliefs. The Pythagorean rule of abstinence from flesh
is thus, in its origin, a taboo resting upon the blood-brotherhood
of men and beasts; and the same line of thought shows a number of
the Pythagoreans: “the number by which all numbers can be
explained” (see Sphaira). The Pythagorean teaching was based upon the
belief that all numbers are divisible into their prime elements,
and the Pythagoreans held that these form only the letters of the
two beliefs. The Pythagorean rule of abstinence from flesh
is thus, in its origin, a taboo resting upon the blood-brotherhood
of men and beasts; and the same line of thought shows a number of
the Pythagorean teaching was based upon the
belief that all numbers are divisible into their prime elements,
and the Pythagoreans held that these form only the letters of the
two beliefs. The Pythagorean rule of abstinence from flesh
is thus, in its origin, a taboo resting upon the blood-brotherhood
of men and beasts; and the same line of thought shows a number of
the Pythagorean teaching was based upon the
belief that all numbers are divisible into their prime elements,
and the Pythagoreans held that these form only the letters of the
two beliefs. The Pythagorean rule of abstinence from flesh
is thus, in its origin, a taboo resting upon the blood-brotherhood
of men and beasts; and the same line of thought shows a number of
the Pythagorean teaching was based upon the
belief that all numbers are divisible into their prime elements,
and the Pythagoreans held that these form only the letters of the
belief that all numbers are divisible into their prime elements,
and the Pythagoreans held that these form only the letters of
self-supported in empty space, revolving with the other planets round a central luminary. They thus anticipated the heliocentric theory, and Copernicus has left it on record that the Pythagorean doctrine of the planetary movement of the earth gave him the first hint of its true hypothesis. The Pythagoreans did not, however, put the sun in the centre of the system. That place was filled by the central fire to which they gave the names of Hestia, the hearth of the universe, the watch-tower of Zeus, and other mythological expressions. The earth, revolving on a circuit round this central fire, and reflected light, and the Pythagoreans (adapting a theory of Empedocles), explained the light of the sun also as due to reflection from the central fire. Round this fire revolve ten bodies, first the Antichthon or counter-earth, then the earth, followed in order by the sun, the moon, the five then known planets and the fixed stars. (a) The central fire and the counter-earth are invisible to us because the side of the earth on which we live is always turned away from them, and our light and heat come to us, as well as the light and heat of the fixed stars, from the side of the earth on the same side of the central fire as the sun, the side of the earth on which we live is turned towards the sun and we have day; when the earth and the sun are on opposite sides of the central fire we are turned away from the sun and it is night. The distance of the revolving orbs from the central fire was determined, according to simple numerical relations, and the Pythagoreans combined their astronomical and their musical discoveries in the famous doctrine of the harmony of the world. (b) This harmony is self-motive and eternal. How we hear the sounds of the different spheres depend upon their distances from the centre, the slower and nearer bodies giving out a deep note and the swifter a high note, the concert of the whole yielding the cosmic octave. The reason why we do not hear this music is that it is not heard in a smith's forge; it can only be heard in a second which they constantly hear and are never in a position to contrast with silence.

 Authorities.—Zeller's account of Pythagoreanism in his "Philosophie der Griechen" gives a full account of the sources, with critical references in the notes to the numerous monographs on the subject, but the history of Pythagoreanism is crowded with uncertainty due to the absence of direct evidence. The more recent scholars have succeeded in clearing up a number of points since he wrote. Diels, "Die Fragmente der Vorsokratiker," vol. i., 2nd ed. 1906; Gomperz, "Greek Thinkers," vol. i., and especially B. B. Warburton, "The History of Greek Mathematics," 2nd ed. 1880, gives an excellent account of the latest investigations. Tannery's "Science hellénique;" Milhaud's "La Science grecque et Philosophes grecs;" Cantor's "History of Mathematics;" and Gow's "Short History of Greek Mathematics," both to the mathematical and physical doctrines of the school.

PYTHAGOREAN GEOMETRY

As the introduction of geometry into Greece is by common consent attributed to Thales, so all are agreed that to Pythagoras is due the honour of having raised mathematics to the rank of a science. We know that the early Pythagoreans published nothing, and that, moreover, they referred all their discoveries back to their master (see PHILOULAS). Hence it is not possible to separate his work from that of his early disciples, and we must therefore treat the geometry of the early Pythagorean school as a whole. We know that Pythagoras made numbers the basis of his philosophical system, as well physical as metaphysical, and that he united the study of geometry with that of arithmetic.

The following statements have been handed down to us. (a) Aristotle (Meta. i. 5, 98b) says: "the Pythagoreans first applied themselves to mathematics, a science which they improved; and, penetrating to the principles that participate in the second body, they laid the principles of all things." (b) Eudemus informs us that "Pythagoras changed geometry into the form of a liberal science, regarding its principles in a purely abstract manner, and investigating the modes of the elements in themselves, without the eye (ἀθανάτως καὶ ἀνόητως)." (c) Diogenes Laërtius (viii. 11) relates that "it was Pythagoras who carried geometry to perfection, after Moeris." (d) He introduces the numerical relations of the musical scale.

Pythagoras, as the first of the systems, is the birthplace of the "axiom" and its converse, the "postulate," and the "counter-postulate," which are the fundamental principles of all scientific method. He is also the inventor of the "perpendicular" and the "parallel" lines, and the "circle" and the "triangle." He is the inventor of the "conic sections," as the ellipse, the parabola, the hyperbola, and the parabola. He is also the inventor of the "perpendicular" and the "parallel" lines, and the "circle" and the "triangle." He is the inventor of the "conic sections," as the ellipse, the parabola, the hyperbola, and the parabola. He is also the inventor of the "perpendicular" and the "parallel" lines, and the "circle" and the "triangle." He is the inventor of the "conic sections," as the ellipse, the parabola, the hyperbola, and the parabola. He is also the inventor of the "perpendicular" and the "parallel" lines, and the "circle" and the "triangle." He is the inventor of the "conic sections," as the ellipse, the parabola, the hyperbola, and the parabola.

1 Proclus, Diadochus, in 'Primum Euclidis elementorum librum commentarii,' ed. Friedel, p. 65.
2 Moeris was a king of Egypt who, Herodotus tells us, lived 900 years before his visit to that country.
4 Lært. viii. 11. (g) Proclus says that the "word mathematics" originated with the Pythagoreans. (h) We learn also from the same authority that the Pythagoreans made a fourfold division of mathematical science, attributing one of its parts to the "how many," another to the "how much," the third to the "how far," and the fourth to the "how many times." They and they assigned to each of these parts a twofold division. They said that discrete quantity or the "how many" is either absolute or relative, and that continued quantity or the "how much" is either measurable or immeasurable. (i) The Pythagoreans contemplate that discrete quantity which subsists by itself, but music that which is related to another; and that geometry considers continued quantity so far as it is immovable, but that astronomy (σφαιρική) contemplates continued quantity so far as it is of a spherical form; and that the Pythagoreans define a point as a "unity having position." (Procl. op. cit. p. 95.) (2) They considered a point as analogous to the monad, a line to the dyad, a superficies to the triad, and a body to the tetrad (ibid. p. 97). (3) They showed that the plane around a point is completely filled by six equilateral triangles, four squares, or three regular hexagons (ibid. p. 305). (4) Eudemus ascribes to them the discovery of the theorem that the interior angles of a triangle are together equal to two right angles. (5) It is confirmed by Plutarch, who says, after Apollodorus, that Pythagoreans laid down the geometrical diagram, either the one relating to the hypotenuse, viz. that the square on it is equal to the sum of the squares on the sides, or that relating to the problem concerning the application of the mean proportional. (6) It is confirmed (ibid. p. 379). (7) Proclus informs us in his commentary on Euclid i. 44 that Eudemus says that the problems concerning the application of the mean proportional is substantially the same as that in Euclid i. 32. (8) Eudemus states that Pythagoras discovered the construction of the regular solids (Procl. op. cit. p. 95.) Hipparcus (the astronomer) judged Pythagoreans to have been the first to have brought the sea on account of his impiety, inasmuch as he boasted that he first divulged the knowledge of the sphere with the twelve pentagons (the inscribed, or the dodecahedron); Hipparchus ascribed to them the glory of the "star-shaped" regular pentagon—which was used as a symbol by the Pythagoreans. (9) It was called by them "health" (ὕπηκους). (10) The triple interwoven triangle or pentagram—star-shaped regular pentagon—was used as a symbol by the Pythagoreans. (11) The discovery of the law of the three
PYTHAGORAS 701

On examining the purely geometrical work of Pythagoras and his early disciples, as given in the preceding extracts, we observe that it is much concerned with the geometry of areas, and we are indeed struck with its Egyptian character. This appears in the fact that there are contained therein five and five parts in the figures for walls or floors covered with tiles of various colours were common in Egypt; in the construction of the regular solids (8), for some of them are found in Egyptian architecture; in the problems connecting the right-angled and the equilateral triangles, which were once suggested by the contemplation of a floor covered with square tiles — the square on the diagonal and the sum of the squares on the sides contain each four of the right-angled triangles into which one of the squares is divided by its diagonal. It easy now to see how the problem to construct a square which shall be equal to the sum of two squares could, in some cases, be solved numerically. From the observation of a chequered board it would be perceived that the element in the successive formation of squares is the gnomon or carpenter's square. Each gnomon consists of an odd number of squares, and the successive gnomons correspond to the successive odd numbers, and include, therefore, all odd squares. So there will be two, or more, right-angled triangles, consisting of the other of nine unit squares, and that it is proposed to form from them another square. It is evident that the square consisting of nine unit squares can take the form of the fourth gnomon, which, in the case of right-angled triangles, consists of a right-angled triangle and the sum of twenty-five unit squares. Similarly it may have been observed that the twelfth gnomon, consisting of twenty-five unit squares, could be transformed into a square each of whose sides consists of a unit square and the sum of other nine unit squares, in which case one of the squares is divided by its diagonal. And the latter square, by taking the gnomonic or generating form with respect to the square on twelve units as base, would produce the square of thirteen units, and so on. This method required only to be verified in order to be ascertained that the rule for finding right-angled triangles whose sides can be expressed in numbers, which, we told, sets out from the odd numbers. The 4th square together with the nth gnomon forms the (n+1)th gnomon, being an odd number, we have 2n+1=m^2, or (n+1)(n+2)=m^2, which gives the rule of Pythagoras.

The general proof of Euclid I. 47 is attributed to Pythagoras, but we have the express statement of Proclus (op. cit., p. 126) that this theorem was not proved in the first instance as it is in the Elements. The following simple and natural way of arriving at the theorem is suggested by Bretschneider after Camerer. A square is dissected into four equal right-angled triangles, as in Euclid II. 4; these two rectangles can, by drawing their diagonals, be decomposed into four equal right-angled triangles, the sum of the sides of each being equal to the side of the square. Hence, when the diagonal of a square is taken, so that a vertex of each shall be in one of the corners of the square in such a way that a greater and less side are in continuation. The original square is thus dissected into the four triangles as before and the figure within, which is the square on the hypotenuse. This square, therefore, must be equal to the sum of the squares on the sides of the right-angled triangle.

It is well known that the Pythagoreans were much occupied with the construction of regular polygones and solids, which in their cosmology played an essential part as the fundamental forms of the elements of the universe. We can trace the origin of these mathematical speculations in the theorem (3) that "the plane triangle, which is the one containing two equal sides, can be divided into two equal right-angled triangles, or three, or four equal hexagons," Plato also makes the Pythagorean Timaeus explain — each straight-lined figure consists of the sides, but all triangles can be dissected into rectangular ones, or the diagonals of the squares, or three regular hexagons. Plato.

10 See Bretsch. Die Geom. vor Euklid, p. 82; Camerer, Euclids eleme. l. 444, and the references given there.

11 The dodecahedron was assigned to the fifth element, quinta pars, ether, or, as some think, to the universe. (See PHILOLAUS.)

squares (Euclid I. 47), commonly called the "theory of Pythagoras," is attributed to him by many authorities, of whom the oldest is Vitruvius. (12) One of the methods of finding right-angled triangles whose sides can be expressed in numbers (Pythagorean triangles), and whose areas have reciprocals of their sides, is ascribed to Pythagoras by Heron of Alexandria and Proclus. (13) The discovery of irrational quantities is ascribed to Pythagoras by Eudemus (Procr. op. cit. p. 65). (14) The three proportions — arithmetical, geometrical, and harmonic — are ascribed to Pythagoras by Iamblichus (4) says, "Formerly, in the time of Pythagoras and the mathematicians under him, there were three means only — the arithmetical, the geometrical and the third in order, which Pythagoras and his friend Archytas (Diogenes Laert. vii. 23) Archytas and Hippasus designated the harmonic, since it appeared to include the ratios concerning harmony and melody." (16) The so-called most perfect or musical proportion, e.g. 6:8:9:12, is said to have been discovered by Pythagoras himself. (17) Iamblichus, (5) is said to be an invention of the Babylonians and to have been first brought into Greece by Pythagoras. (18) Arithmetical progressions were treated by the Pythagoreans, and it appears from a passage in Lucian that Pythagoras himself had considered the special case of triangular numbers: Pythagoras asks some one, "How do you count?" He replies, "One, two, three, four." Pythagoras, interrupting, says, "Do you see what you take to be four, that is ten and a perfect triangle and our oath! (18) The odd numbers were called by the Pythagoreans "gnomons," and were regarded as generating, in such a manner, as the multiplication of successive gnomons — consisting each of an odd number of squares — to the theorem of the square was preserved. (19) In like manner, if the simplest oblong (tupra, 5) consisting of two unit squares monads in juxtaposition, be taken and four unit squares be placed about it after the form of one unit square, .. two bold squares be placed in second, the oblong form will be preserved. (20) Another of his doctrines was, that all odd figures the sphere was the most beautiful, and of all plane figures the square was the most beautiful. (21) The Pythagoreans are said to have found the quadrature of the circle, as him a symbol of health. It is said to have obtained its especial name from the letters y, v, d (a), e, as having been at its prominent vertices.

12 De arch. xi.; Procr. x. 5, 7. Amongst other authorities are Diodorus Siculus, l. 126 (Acad. Lat. vii. 23), and Pliny, Nat. hist. x. 32, (ut supra, 6). Plutarch, however, attributes to the Egyptians the knowledge of this theorem in the particular case where the sides are 3, 4, and 5 (De Is. et Osir. c. 50).

13 Heron Alex. Geom. et stereom. tela., ed. F. Hultsch, pp. 56, 146; Procr. op. cit. p. 428. The method of Pythagoras is as follows: he took an odd number as the lesser side; then, having squared this number and diminished the square by unity, he took half of the greater side, and by adding unity to this number he obtained the hypotenuse, e.g. 3, 4, 5, 5, 12, 13.

15 In Nicomach. arithmeticae, ed. S. Tennusius, p. 141.

16 Nicom. is of the proportion. Nicomachus and, after him, Iamblichus gives the numbers 6, 8, 9, 12, the harmonic and arithmetical means between two numbers forming a geometric proportion with the numbers themselves (tupra, 5).

17 Iamblichus further relates (loc. cit.) that many Pythagoreans made use of this proportion, as Aristaeus of Crotone, Timaeus of Locri, Philolaus and Archytas of Tarentum and many others, and after them Plato in his Timaeus (see Nicom. Inst. arithm., ed. Ast., p. 153; and Anamnesticorum, pp. 327-329; and lamb. op. cit. p. 172 seq.).

PYTHAGORAS

solids three—the tetrahedron, the cube and the octahedron—were known to the Egyptians and are to be found in their architecture. Let us now examine what is required for the construction of the other two solids—the icosahedron and the dodecahedron. In the formation of the solid, four equilateral triangles are placed with a common vertex and adjacent sides coincident; and it was known that if six such triangles were placed round a common vertex with their adjacent sides coincident, the result was a regular hexagon. But if the same number were therefore, no solid could be formed in that manner from them. It remained, then, to try whether five such equilateral triangles could be placed at a common vertex in like manner; on trial it would be found that they could be so placed, and that they would form a regular pentagon. The existence of a regular pentagon would thus become known. It was also known from the formation of the cube that three squares could be placed in a similar way with a common vertex; and that, further, if three equal and regular hexagons were placed round a point as common vertex with adjacent sides coincident, they would form a plane. It remained in this case, too, only to try whether three equal regular pentagons could be placed with a common vertex and in that way: this on trial would be found possible and would lead to the construction of the regular dodecahedron, which was the regular solid last arrived at.

The proof on the construction of the regular pentagon is required for the formation of each of these two regular solids, and that, therefore, it must have been a discovery of Pythagoras. If we examine now what knowledge of geometry was required for the solving of this problem, it will be found that it requires a knowledge of the theory of proportion, which is reduced to Euclid II. 11, which problem is reduced to the following: To produce a given straight line so that the rectangle contained by the whole and some part of it shall be equal to a given square. This was known from the observations of the ancients. To apply to a given straight line a rectangle which shall be equal to a given area—in this case the square on the given line—and which shall be excessive by a square. Now it is to be observed that this problem is solved by means of a right-angled triangle, and in a similar way: this on trial would be found possible and would lead to the construction of the regular dodecahedron, which was the regular solid last arrived at.

The theorem that similar polygons are to each other in the duplicate ratio of their homologous sides involves a first sketch, at least, of the doctrine of proportion and the similarity of figures. That we owe the foundation and development of the doctrine of proportion to Pythagoras and his school is confirmed by the testimony of Nicomachus (14) and Iamblichus (15 and 16). From these and other sources we find that Pythagoras and his school used not only the arithmetical and geometrical means between two magnitudes, but also with their harmonical mean, which was then called "subcontrary."

The Pythagoreans were much occupied with the determination of numbers and the rectangles or squares formed by the numbers. The method employed was to find the Pythagorean triangles (12) and the observations therein. On the other hand, there is no evidence to support the statement of Montucla that Pythagoras laid the foundation of the doctrine of isoscelesity, by proving that all figures having the same base and contained by the same perpendicular have the same surface. This could not be the case if the circle were the greatest of all geometrical figures. It is also stated that Pythagoras and his school were the first to use the geometrical figures from the needs of practical life, and treated it as a liberal science, giving definitions and introducing the manner of proof which has ever since been in use. Further, they distinguished between discrete and continuous quantities, and regarded geometry as a branch of mathematics, of which they made the fourfold division that lasted to the middle ages—the quodivium (fourfold way to knowledge) of Boetius and the scholastic philosophy. And it may be observed that the name of "mathematics," as well as that of "philosophy," is ascribed to them. Thirdly, as to form.

The chief characteristic of the mathematical work of Pythagoras was the

PYTHAGORAS (OF RHUEGUM)—PYTHEAS (OF MARSEILLES) 703

combination of arithmetic with geometry. The notions of an
equation and a proportion—which are common to both, and
contain the first germ of algebra—were introduced among the
Greeks by Thales. These notions, especially the latter, were
elaborated by Pythagoras and his school, so that they reached
the rank of a true scientific method in their theory of proportion.
To Pythagoras, then, is due the honour of having supplied a
method which is common to all branches of mathematics, and
in this respect he is fully comparable to Descartes, to whom we
owe the decisive combination of algebra with geometry.

See G. J. Allman, Greek Geometry from Thales to Euclid (Cambridge, 1889); M. Cantor, Vorlesungen über Geschichte der Mathematik (Leipzig, 1892); James Gow, Short History of Greek Mathematics (Cambridge, 1884). (C. G. A.)

PYTHAGORAS, of Rhuegum, a noted Greek sculptor of the
5th century B.C., a contemporary of Myron and Polyclitus, and
their rival in making statues of athletes. He was born at
Samos and migrated in his youth to Rhuegum in Italy. He
made a statue of Philoctetes notable for the physical expression
of pain, an Apollo shooting the Python at Delphi, and a man
singing to the lyre. He is said to have introduced improve-
ments in the rendering of muscles, veins and hair.

PYTHEAS, of Marsiilia, a celebrated Greek navigator and
geographer, from whom the Greeks apparently derived
their earliest definite information concerning western Europe,
and especially the British Islands. He was probably contem-
porary with Alexander the Great; he certainly wrote before
Dicaearchus, a pupil of Aristotle who died about 285 B.C. His
work is lost, and we are left almost wholly in the dark as to its
form and character. One simple rule under which it is quoted
(e.g., Γῆς περιοίδου, or Τα τού ἕλεον) points to a
geographical treatise, in which Pytheas had embodied the
results of his observations, rather than to a continuous narrative
of his voyage.

Some modern writers have supposed Pytheas to have been
sent out, at public expense, in command of an expedition or-
ganized by the republic of Marsiilia; but there is no ancient authority
for this, and Polibius, who had unquestionably seen the original
work, expressly states that he had undertaken the voyage in a
private capacity and with limited means. All that we know
concerning the voyage of Pytheas (apart from detached notices)
is contained in a brief passage of Polibius, cited by Strabo,
in which he tells us that Pytheas, according to his own statement,
had not only visited Britain, but had personally explored a large
part of it ("travelled all over it on foot," according to one reading
of the passage by Strabo), and had circumnavigated the British
coast at more than 40,000 stadia (4000 geographical
miles). To this he added the account of Thule (which he placed
six days' voyage north of Britain) and the adjoining regions,
in which there was no longer any distinction between air, earth
and sea, but a kind of mixture of all three, resembling the gela-
tinous mollusc known as pulmo marinus, which rendered all
navigation and progress in any other mode alike impossible.
This substance Pytheas had himself seen, according to Strabo
(bk. iv. ch. i.), but the other phenomena he described only from
hearsay. After this he visited the "whole of the coasts of Europe" (i.e.,
those bordering on the ocean) as far as the Tanais (Strabo,
bk. ii. ch. iv. § 1). This last sentence has led some modern
writers to suppose that he made two different voyages; but this
is improbable; the expressions of Polibius imply that his ex-
ploitations in both directions, first towards the north and after-
wards towards the east, formed part of the same voyage.

This voyage of Pytheas was described in a work of 94 books,
by Pytheas which was previously unknown to the Greeks—except, perhaps, by vague
accounts received through the Phoenicians—and were not visited
by any subsequent authority during more than two centuries.
He was probably one of the later Greek geographers altogether disregarded
his statements, and treated his voyages as a fiction. Eratosthenes,
indeed (276-196 B.C.), attached great value to his authority as to
Britain and Spain, though doubting some of his statements; but
Hecataeus of Polis (404-122 B.C.) considered the whole work of Pytheas
a tissue of fables, like that of Ephemerides concerning Panchaea;
and even Strabo, in whose time the western regions of Europe were
comparatively well known, adopted to a great extent the view
of Polibius.

In modern times a critical examination has arrived at a more
favourable judgment, and though Gosse (in his Recherches sur
la geographie des anciens (ii., 168-180) and Sir G. C. Lewis in his
History of Ancient Astronomy (pp. 469-481) revived the sceptical
opinion that any such voyage must have been rather
than to depreciate the value of what was really added by Pytheas
to knowledge. Our information concerning him is so imperfect,
and the scanty notices preserved to us from his work are so meagre
that it is not improbable that he exaggerated in some respects.
It may, however, be considered as fairly established that
Pytheas made a voyage round the western coasts of Europe,
proceeding from Gades, the great Phoenician emporium, and,
probably, in the winter of 426 B.C., he penetrated north of Spain and Gaul
to the British Islands, and that he followed the eastern coast of
Britain for a considerable distance to the north, obtaining in-
formation as to its farther extension in that direction which led
him to exaggerate its extent. At the same time he heard vaguely
of the existence of the island of Britannia, which was probably
derived from the fact of the Orkneys and Shetlands being really
found in that position—to which he gave the name of Thule.

His most important statement made by Pytheas in regard to
Thule was that was connected with the mythical phenomena affecting
the duration of day and night therein. Unfortunately the
reports transmitted to us differ so widely that it is almost impossible
to determine what Pytheas himself stated. It is, however, probable
that the distance given by Ptolemy (His. Etr., iv. 35) 6000
miles) correctly represents his authority. According to this, the
days at the summer solstice were twenty-four hours in length, and
versely at the winter solstice the nights were of equal duration.
Of the lands to the south-west of Pytheas's Arctic Circle, which Pytheas evidently considered it to be, and his
skill as an astronomer would lead him to accept as a fact
what he knew to be true at some point as a voyager proceeded onwards
over the north.

Still more difficult is it to determine the extent and character
of Pytheas's explorations towards the east. The statement
that he proceeded along the coasts of Europe from Gades to the Tanais
is connected with a simple rule and direct course along the northern shores of Germany and Scythia—
Polybios himself, in common with the other Greek geographers till a much later period, being ignorant of the projection of the
Degree or Circle, in thinking that it was involved—of all which no trace is found in the extant notices of
Pytheas. Notwithstanding this, some modern writers have
supposed him to have entered the Baltic and penetrated as far as the
Vilm, to which he gives the name of Teminenos.1

In the fact that in a passage cited by Ptolemy (H. N. xxxvi., 2, 35) Pytheas is represented as stating that amber was brought from an
island called Alalus, distant a day's voyage from the land of the
Gutrones, a German nation who dwelt on an estuary of the ocean
called Mentonumos, 6000 stadia in extent. It was a production
thrown up by the waves of the sea, and was used by the inhabitants
to burn instead of wood. It has been conjectured that the "estuary"
here mentioned would refer to the estuary of the Elbe, near
Schleswig, as well as in the Baltic, though not in equal abundance.
As to the Cassiterides, or Tin Islands, the exploration of which
would naturally be the first object of a voyager, it seems
probable, as Timaeus, who wrote less than a century after him,
with details upon the same, especially in regard to the commercial
centre of Iktis (St Michael's Mount in Cornwall), which are
preserved in the fragment of Strabo, that Pytheas probably
visited these islands at this period in Phoenician hands, but we know that at a later time
a considerable portion of the supply was carried overland through
Gaul to Massilia.

Pytheas certainly had one merit which distinguished him
from almost all his contemporaries—he was a good astronomer,
and was one of the first who made observations for the deter-
imination of latitudes, among others that of his native place Massilia,
which was on the coast of the Adriatic, was within a few miles of the truth, was adopted by Ptolemy, and
became the basis of the Ptolemaic map of the western Medi-
terranean. His calculations of the length of the longest day at four
centuries (16, 17, 18 and 19 hours) are to be pressed, they would refer to, say, Ushant (48° N.),Flam-
borough Head (54°), Tarbert Ness in Ross (58°) and the northern-
most Shetlands (61°). Pytheas was also the first among the
Greeks who arrived at any correct notion of the tides, and not only indicated their
connexion with the moon, but pointed out their periodical
fluctuations in accordance with the phases of that luminous. Other
observations concerning the manners and customs of the inhabitants
of remote northern regions prove that he had himself really visited them. Among these are the gradual disappearance of various kinds of grain as one advanced towards the north; the use of fermented liquors made from corn and honey; and the habit of threshing out their corn in large covered barns, instead of on open threshing floors as in Greece and Italy. The python finds its way to the sun and abundance of rain. Pytheas's notice of the depth of the Bay of Biscay, of the length of the projection of Brittany, of the name of Uxiusma, and of three promontories of Britain two of which seem to correspond to Land's End (Belerus), and North Foreland (Kantion), must not be forgotten.

The fragments of Pytheas have been collected by Arvedson (Upsala, 1824), and by Fuhr (De Pythea massiliensi, Darmstadt, 1835). Of the numerous treatises and dissertations on the subject, see: Ubert, 'Bemerkungen über Pytheas,' in vol. 1 of his Geo. d. Griechen u. Römer, pp. 298-309, which contains an excellent summary of all that is known concerning Pytheas; Sir George C. Lewis, Historical Survey of the Astronomy of the Ancients, pp. 456-480 (London, 1852); Sir Edward H. Bunbury, History of Ancient Geography, vol. 1, ch. xv. § 2 (London, 1883); C. I. Elton, Origins of English History, of. especially app. i. pp. 400, &c. (London, 1882); Hugo Berger, Geschichte der wissenschaftlichen Erdkunde der Griechen, pt. 3 (2nd ed., Leipzig, 1903). A very elaborate investigation of the whole subject will be found in Müllerhoff, Deutsche Alterthumskunde, i. 211-497 (Berlin, 1870). See also Sir Clemen's Markham's paper, "Pytheas, the Discoverer of Britain," in the Geographical Journal (June 1893); and H. F. Tozer, History of Ancient Geography, pp. 152-164 (Cambridge, 1897). (E. H. B.; C. R. B.)

**PYTHIS, or PYTHUS, one of the most noted Greek architects of the later age.** He cultivated the Ionic style, in which he constructed the temple of Athena at Priene. The dedicatory inscription, which is in the British Museum, records that the founder was Alexander the Great. Pythis also made a great marble quadriga which surmounted the Mausoleum.

**PYTHON, in Greek mythology, son of Gaea, an enormous serpent, said to have been produced from the mud after the flood of Deucalion.** Its haunt was a cavern near Mt. Parnassus. Four days after its birth it was slain by Apollo (Apollodoros i. 4), who was hence surnamed Pythis. According to Ephorus (in Strabo ix. 646), Python, surnamed Dracon (serpent), was a brigand near Delphi. The python in reality represents the pestilential vapours rising from stagnant lakes and pools, which are dispersed by Apollo and his arrows—that is, the shafts of the sun. The old derivation (Homeric Hymn to Apollo, 371), according to which Delphi was originally called Pytho, because the slain serpent was left there to "rot" (ριθεόντα), points to this explanation.

See C. Pascal, *Studi di antichità e mitologia* (1896).

**PYTHON, a genus of very large snakes of the family Boidae (see Snakes) inhabiting the tropical parts of Africa, Asia and Australia.** They differ from the true boas (g.g.), with which they are often confused by carrying a few teeth in the maxillary, by the double row of subcaudal shields and by the possession of a pair of supraorbital bones. Most of them have pits in some of the upper and lower labial shields.

*Python reticulatus* is the commonest species in Indo-China and the Malay Islands; four upper labial shields on either side are pitted. It is, next to the *Anaconda*, one of the largest of all snakes, some specimens being known which measured about 30 ft. in length. *P. molurus*, scarcely smaller, is the python or rock-snake of India and Ceylon. The African species are much smaller, up to 15 ft. in length, e.g. *P. sebae* of tropical and southern Africa and the beautiful *P. regius* of Western Africa. *P. spilotes* is the "carpet-snake" of Australia and New Guinea. A small relative of pythons is *Loxocemus bivolor* of South Mexico, the only New World example.

The giant pythons could no doubt overpower and kill by constriction almost any large mammal, since such snakes weigh many hundredweights and possess terrific strength, but the width of their mouth—although marvellously distensible—has, of course, a limit, and this is probably drawn at the size of a goat. Before a python swallows such large prey, its bones are crushed and the body is mangled into the shape of a sausage. The snake begins with the head, and a great quantity of saliva is discharged over the body of the victim as it is hooked into the throat by the alternately right and left forward motions of the distended well-toothed jaws. If for any reason a snake should disgorge its prey, this will be found smothered with slime. Hence the fable that they cover it with saliva before deglutition.

Most pythons are rather ill-tempered, differing in this respect from the boas. They are chiefly arboreal, and prefer localities in the vicinity of water to which mammals and birds, their usual prey, resort. They move, climb and swim with equal facility. The female collects her eggs, sometimes as many as one hundred, into a heap, round which she coils herself, covering them so that her head rests in the centre on the top. In this position the snake remains without food throughout the whole period of incubation, or rather keeping guard, for about two months. (H. F. G.)

**PYX** (Gr. πυξ, a box or chest), a term for various forms of receptacle. In ecclesiastical usage it is the sacred vases or tabernacle in which the Host is reserved. In the English Mint the pyx is the chest in which are placed one coin from every 15 lb of newly coined gold and one from every 60 lb of newly coined silver to await the "trial of the pyx" (see MINT). This chest was formerly kept in the Chapel of the Pyx in Westminster Abbey.
Q—QARAITES  705

the letter which immediately succeeds P in the alphabet of Latin and the modern languages of western Europe. It represents the Koppa of the earliest Greek alphabets surviving in that form of the Ionic alphabet, which ultimately superseded all others, merely as the numerical symbol for 99. In the Phoenician alphabet a sibilant Zade (Tzaddi) stands between q and p. Hence Q is the nineteenth letter in the Phoenician alphabet, the eighteenth in the Greek numerical alphabet, which alone contains it, the sixteenth (owing to the omission of θ and χ) in the Latin, and (from the addition of J) the seventeenth in the English alphabet. Its earliest form is a rough ellipse transixed by an upright line, Q. In various Semitic alphabets this has been altered out of recognition, apparently from the writing of the symbol in cursive handwriting without lifting the pen. As a result forms like Q, P, T, T are developed. In Greece the head of the symbol is generally circular, and only in a few early inscriptions is the upright carried through the circle, Q. The common form is Q with the upright stem short. This is also the earliest form in the Latin alphabet, but forms with the upright turned to the right as in a modern Q are found in the Republican period, while this tail becomes longer and curved in the early Empire. The pronunciation of the Semitic Koph (Qoph) was that of a velar guttural produced against the back part of the soft palate with great energy (hence called an "emphatic" sound). In Greek there is no evidence that Q was pronounced differently from K; hence no doubt its early disappearance in most dialects. It survived longest when followed by ο or υ, as at the beginning of the name of the town of Corinth. In Latin it is regularly used in combination with u. In classical Latin its use is confined to the cases where, as in English quit, &c., the w is pronounced as t before a following vowel, but in old Latin it is found also in other combinations. Many languages find the combination qw, when both sounds are consonantal (qg), difficult; q being the deepest guttural while w (English w) is a lip sound, the points of production are nearly as far separate as they can be. There is thus a tendency to assimilation, and instead of a guttural followed by a labial semi-vowel, a new labial consonant p is produced. In Greek this is common when the combination is followed by the vowel ο, as in ποῦ, ποτ, &c., from the same stem as the Latin qui, quae, &c. This, however, is not found in all dialects alike (see Greek Language). In other languages, like Occan and Umbrian which are closely akin to Latin, or the Welsh branch of the Celtic languages, p occurs regularly without regard to the nature of the vocal following. Thus, corresponding to the Latin quattuor, we find the Occan petau, the Gaulish petoritum, "four-wheeler," the Welsh pedwar, "four," &c., while the Irish cethir, "four," corresponds more closely to the Latin. (P. Gl.)

QARAITES, or QARAITES, a Jewish sect of the middle ages, claiming to be distinguished by adherence to Scripture as contrasted with orthodox tradition, whence the name (from παρά qara, to read, as if "readers," scripturarii; sometimes also κηρώς "children of the Text" as read). They have frequently been identified with the Sadducees or with the Samaritans, with neither of whom have they any historical connexion or much spiritual affinity. The schism arose at Bagdad about the middle of the 9th century, when the hereditary claims of Anan, a priest of the Talmud, to the chief of Rish Galutha were set aside by the Gaonim (heads of rabbinical schools) of Pumbeditha, because he was believed to undervalue the authority of the Talmud. Anan, nevertheless, allowed himself to be proclaimed Exilarch by his followers, a step construed into treason by the Mahomedan government. He was sentenced to death, but his life was saved by his fellow prisoner, Abu Hanifa, the founder of the great school of Moslem theology and jurisprudence. Ultimately he and his followers were permitted to migrate to Palestine. They erected a synagogue in Jerusalem which continued to be maintained until the time of the Crusades. From this centre the sect diffused itself thinly over Syria, spread into Egypt, and ultimately reached S.E. Europe.

Anan, who is said to have died in A.D. 765, was the author of a commentary on the Pentateuch and other works in Talmudic Hebrew and Arabic. Most of these are lost, and we are thus left chiefly dependent on the hostile indications of opponents. His code was recovered in Egypt by the Qaraite Moses b. Elijah Basyazî (1544–1572). Fragments were published by Harkavy (Voskod 1897–1898). It is clear that Anan, although theoretically antagonistic to rabbinic methods, was in the end compelled to incline towards them. Considerable influence, too, was exercised on his theology by Abu Hanifa. In general we know that he showed great bitterness against the Talmud and its upholders (the "Rabbanites") for their modification of the written law by arbitrary additions and subtractions, but there is nothing to indicate that he himself had the insight or the fervour by which he could leave the pioneer of a really great reformation. The questions appear to have turned entirely on points of minute detail. Several of them related to the regulation of the calendar, the new moon, for example, being fixed by the Qaraite by direct observation, not by astronomical calculation, and the intercalary year also being determined empirically; others related to paschal and pentecostal ritual, such as the precise hour for killing the lamb or for burning its remains. The differences which affected social life most deeply were those relating to Sabbath observance and the forbidden degrees of marriage, the Qaraite not recognizing any distinction between relationships of consanguinity and those of affinity, while in their zeal to avoid all risk of infringement of the sacredness of the day of rest they prohibited the burning of any light at all in their houses from sunset to sunset.

Of late years much Qaraite literature has been published. The most valuable contribution to learning made by it is in the direction of Hebrew philology and the natural exegesis of the scriptural text. Little information as to the Qaraite can be derived from their liturgies; they differ fundamentally from those used by Rabbanites in being composed almost entirely of scriptural versions and in containing practically no Piyyudim (liturgical poems). The controversies as to the rule of faith which so deeply divided the Christian Church in the 16th century gave to this obscure sect an illusory and passing importance, the Catholics frequently hurling the epithet Karaei, in token of contempt, at the Protestants, who in their turn unwillingly accepted it as sufficiently descriptive of their attitude towards Scripture. The Qaraites never have been numerous; in 1904 their total number was estimated at 12,000, 10,000 being found in Russia: the present community in Jerusalem numbers only a few families. They occur in Constantinople and elsewhere in Turkey, and in Egypt, but are chiefly met with in southern Russia, and especially in the Crimean districts of Eupatoria, Theodosia and Sevastopol. Here their historical capital and chief synagogue was formerly the "Jews’ Castle" (Tshujut-Kale), near Bakh-chisarai. The place is now deserted; its cemetery was the seat of Firkowitsch’s notorious forgeries (inscriptions of 1st century), by which he sought to establish Jewish antiquity for his sect. According to Strack (A. Firkowitsch u. seine secten, 1903) the Qaraite do not go back beyond the 14th century. The modern Qaraites are generally well spoken of for their honesty, perseverance and simple habits of life; they are gradually approximating to the Rabbanites, with whom, in some places, they are on terms of social intimacy. The Russian government exempts the Qaraite from the restrictions to which the rest of the Jews are subject; this circumstance is probably due to the insignificance of the Qaraites numerically.

Among the older authorities may be mentioned Morinus, Exercit. Bibl. lib. ii. ex. 7 (1669); and Triglandius, Diatribe de Socia Karaseorum
QARO—QUADRILATERAL

(1701). See Grätz, Gesch. der Juden, especially in vol. v. (1806), with the additions and corrections of Harkavy in the Hebrew translation; and Fürst, Gesch. des Karderethums (1865); S. Pinsker, Lippate Qudmontiyot; articles by A. Harkavy and by S. Poznanski in the Jewish Quarterly Review (e.g. x. 238–276, and vols. xvii.–xx.). See also Jewish Encyclopedia, s.v. “Anan,” “Karaite,” &c.

QARO (or CARO), JOSEPH BEN EPHRAIM (1488–1579), codifier of Jewish law, whose code is still authoritative with the mass of Jews, was born in 1488. As a child he shared in the expulsion from Spain (1492), and like most prominent Jews of the period was forced to migrate from place to place. In 1535 he settled in Safed, Palestine, where he spent the rest of his life. Safed was then the headquarters of Jewish mysticism. Qaro was himself a mystic, for the tribulations of the time turned many men’s minds towards Messianic hopes; nor was he by any means the only great Jewish legalist who was also a mystic. Mysticism in such minds did not take the form of a revolt against authority, but was rather the spiritual flower of pietism than an expression of autonomism. It is, however, as a legalist that Qaro is best known. In learning and critical power he was second only to Maimonides in the realm of Jewish law. He was the author of two great works, the second of which, though inferior as an intellectual feat, has surpassed the first in popularity. This was inevitable, for the earlier and greater book was designed exclusively for specialists. It was in the form of a commentary (entitled Beth Yoseph) on the Turim (see ‘Asher Ben Yehiel). In this commentary Qaro shows an astounding mastery over the Talmud and the legalistic literature of the middle ages. He felt called upon to systematize the laws and customs of Judaism in face of the disintegration caused by the Spanish expulsion. But the Beth Yoseph is by no means systematic.

Qaro’s real aim was effected by his second work, the Shulhan Arukh (“Table Prepared”). Finished in 1555, this code was published in four parts in 1565. The work was not accepted without protest and criticism, but after the lapse of a century, and in consequence of certain revisions and amplifications, it became the almost unquestioned authority of the whole Jewish world. Its influence was to some extent evil. It “put Judaism into a Strait-jacket.” Independence of judgment was inhibited, and the code stood in the way of progressive adaptation of Jewish life to the life of Europe. It included trivialities by the side of great principles, and retained elements from the past which desired to fall into oblivion. But its good effects far outweighed the bad. It was a bond of union, a bar to latitudinarianism, an accessible guide to ritual, ethics and law. Above all, it gave a new lease of life to the great theory which identified Jewish life with religion. It sanctified the home, it dignified common pursuits. When, however, the era of reform dawned in the 19th century, the new Judaism found itself impelled to assume an attitude of hostility to Qaro’s code.

QUACK, one who pretends to knowledge of which he is ignorant, a charlatan, particularly a medical impostor. The word is a shortened form of “quack salver” (Du. kwaksalver), in which form it is common in the 17th century, “salver” meaning “healer,” while “quack” (Du. kwakken) is merely an application of the onomatopoeic word applied to the sounds made by a duck, i.e. gabble or gibberish. In English law, to call a medical practitioner a “quack” is actionable per se without proof of special damage. Alb. v. Eaton (1636), 1 Roll. (Ab. 92). The Office of a “quack doctor” was legally defined as “in stamp,” i.e. a board, or a second-hand pretender to medical skill, but a “quack” may have great skill, and it is the claim to cure by remedies which he knows have no efficacy which makes him a “quack” (see Dakkyev v. Labouchere, The Times, 20th of July 1904, and 5th and 9th of November 1907).

QUADRATIX (from Lat. quadrator, squarer), in mathematics, a curve having ordinates which are a measure of the area (or quadrature) of another curve. The two most famous curves of this class are those of Dinostratus and E. W. Tschirnhausen, which are both related to the circle.

The quadratrix of Dinostratus was well known to the ancient Greek geometers, and is mentioned by Proclus, who ascribes the invention of the curve to a contemporary of Socrates, probably Hippos of Elis. Dinostratus, a Greek geometer and disciple of Plato, discussed the problem, and showed how it effected a mechanical solution of squaring the circle. Pappus, in his Collect. Notes, gives two methods by which it can be generated.

1. Let a spiral line be drawn on a right circular cylinder; a screw surface is then obtained by drawing lines from every point of this spiral perpendicular to its axis. The orthogonal projection of a section of this surface by a plane containing one of the perpendiculars and inclined to the axis is the quadratrix.

2. A right cylinder has one of its bases inscribed in a circle so related to P that the ordinate QP moves from A to O in the same time as the vector OM describes a quadrant. Then the locus of the intersection of P and QM is the quadratrix of Dinostratus.

The cartesian equation to the curve is

\[ y = x \cot \frac{x}{y}, \]

which shows that the curve is symmetrical about the axis of y, and that it consists of a central portion flanked by infinite branches (fig. 2). The intercepts are \( x = 2n \), \( n \) being an integer. The intercept on the axis of y is \( 2a/x \); therefore, if it were possible to accurately construct the curve, the quadrature of the circle would be effected. The curve also permits the solution of the problems of duplicating a cube (g.), and trisecting an angle.

The quadratrix of Tschirnhausen is constructed by dividing the arc and radius of a quadrant in the same number of equal parts as are given to the ordinates of the lines drawn from the points of division of the arc parallel to AB, and the lines drawn parallel to BC through the points of division of AB, are points on the quadratrix at the corresponding angle. The equation is

\[ y = a \cos \frac{\pi x}{2a}. \]

The curve is periodic, and cuts the axis of x at the points \( x = 2n-1, n \) being an integer; the maximum values of y are \( x = a \). Its branches are similar to those of the quadratrix of Dinostratus.

QUADRATURE (from Lat. quadratura, a making square), in astronomy, that aspect of a heavenly body in which it makes a right angle with the direction of the sun; applied especially to the apparent position of a planet, or of the moon at first and last quarters. In mathematics, quadrature is the determination of a square equal to the area of a curve or other figure.

QUADRIGA, the ancient four-horsed chariot (Lat. quadrigae, contracted from quadriiugae), which was regarded as one of the seven sacred features in Rome. It was chiefly used as the triumphal char of generals or emperors. The earliest example mentioned is that which was modelled in terra-cotta and raised on the pediment of the temple of Jupiter Capitolinus. In later time it formed the chief decorative feature which crowned the triumphal arches, and there are numerous representations of it on coins.

QUADRILATERAL, in geometry, a figure enclosed by four straight lines. It is also a military term applied to a combination of four fortresses mutually supporting one another. The fortresses of Namur, Liége, Maastricht, and Louvain, and also those of Silistra, Rustschuk, Shumla, and Varna, were so called. But the most famous quadrilateral was that of the four fortified towns of north Italy—Mantua, Peschiera, Verona, and Legnago.
the two former of which are situated on the Mincio and the two latter on the Adige. The real value of the quadrilateral, which gave Austria such a firm hold on Lombardy, lay in the great natural strength of Mantua and in the readiness with which troops and supplies could be poured into Verona from the north.

QUADRILLE, the name of a game of cards and of a dance.

The game, played by four persons with a pack of forty cards, was a variation of the Spanish game of ombre (q.e.) and superseded it in popularity about 1725, to give way in turn to whist. The dance is of French origin and is usually danced by four couples in square. In the 18th century the contredanse was introduced into the ballet, and groups of four, eight or twelve dancers dressed alike performed different figures; these were first called quadrilles des contredances, later shortened to quadrilles. The dance became popular outside the ballet, and its figures, five in number, with a finale, bore the names of the different contredances, Le Pantalon, l’Ét, La Poule, La Trinité, La Pastourelle. The dance was introduced into England in 1815. The word in both its applications comes through It. quadrigio or Span. cuadrilla from Lat. quadra, a square, four-sided figure (quattuor, four).

QUADROON (a corruption of quarteron, Span. cuarteron, from cuarto, Lat. quartus, fourth), strictly a person having one-fourth negro blood, the offspring of a mulatto and a white. The children of a mulatto and a negro are called in America sambos or sambos (possibly from Span. sambro, Lat. sambus, bow-legged), and the use of Sambo as a proper name for a black servant may have thus originated.

QUAESTOR (from Lat. quaero, investigate), a Roman magistrate whose functions, at least in the later times of the republic, were mainly financial, though he was originally concerned chiefly with criminal jurisdiction. The origin of the quaestorship is obscure, but it was probably instituted simultaneously with the consulship in 509 B.C. The number of the quaestors was originally two, but this was successively increased to four (in 421 B.C.), eight (in 267 or 241 B.C.), and by Sulla (in 81 B.C.) to twenty. Julius Caesar raised the number to forty (in 45 B.C.), but Augustus reduced it again to twenty, which remained the regular number under the empire. The original quaestors were afterwards distinguished by the title of urban quaestors (quaestores urbani). When the number was raised from two to four in 421 B.C. the office was thrown open to the plebeians. It was the lowest of the great offices of state and hence it was regularly the first sought by aspirants to a political career (cursus honorum). Towards the close of the republic, if not earlier, the successful candidate was bound to have completed his thirtieth year before he entered on office, but Augustus lowered the age to twenty-five. Originally the quaestors seem to have been nominated by the consuls, but later, perhaps from the fall of the decemvirs (449 B.C.), they were elected by the people assembled in tribes (comitia tributa) under the presidency of a consul or another of the higher magistrates. The quaestors held office for one year, but, like the consuls and praetors, they were often continued in office with the title of proquaestor. Indeed it was a rule that the quaestor attached to a higher magistrate was his subordinate in his own province: thus the quaestor was a consul regularly presided over the city for one year, and afterwards as proconsul governed a province for another year, his quaestor also regularly held office for two years. Before the election of the quaestors the senate decided the duties to be undertaken by them, and after election these duties were distributed amongst the new quaestors either by lot or by the choice of the higher magistrates to whom quaestors were assigned. A peculiar burden laid on the quaestors, not as an official duty, but rather as a sort of fee exacted from all who entered on the political career, was the paving of the high roads, for which Claudius substituted the exhibition of gladiatorial games.

Various classes of quaestors may be distinguished according to the duties they had respectively to discharge.

1. The Urban Quaestors.—Originally the duties of the quaestors, like those of the consuls, were undefined; it was the same that was usually done by the superior magistrates of the republic, the quaestors their assistants. From a very early time, however, the quaestors possessed criminal jurisdiction. In the code of the Twelve Tables they are designated quaestores parricidii (the case of parricide), and perhaps originally this was their full title, which was afterwards abbreviated into quaestores when their functions as criminal judges fell into the background. In addition to parricide or murder we can doubt the permission of any other and inferior distinction of the quaestors; political crimes only seem to have been excepted.

The criminal jurisdiction of the quaestors appears only to have terminated when towards the close of the republic trial by permanent courts (quaestiones perpetuae) was extended to criminal cases.

2. The Military Quaestors.—These were instituted in 421 B.C., when two new quaestors were added to the quaestors of the two. They never had a distinctive appellation like that of the urban quaestors, from whom, however, they were clearly distinguished by the fact that, while the urban quaestors did not stand in a special relation of service to any particular magistrate, a non-quaestor, quaestor or praetor, was regularly assigned as an indispensable assistant or adjutant to every general in command, whose name or title the quaestor usually added to his own. Originally they were the assistants of the quaestor in the drawing up of the estimates of revenue and expenditure (quaestiones), and in the collection of the province; they were later transferred to the quaestor, but the office itself continued to exist into the 3rd century, though as to the nature of the duties attached to it we have little or no information.

3. The Italian Quaestors.—The subjugation of Italy occasioned the institution (in 267 B.C.) of four new quaestors, who appear to have been called quaestores classici because they were originally intended to superintend the finances of the state. These quaestors, however, are very imperfectly known. Though no doubt intended to assist the consuls, they were not subordinated (like the military quaestors) to a special consul. They were stationed at Rome, at Caere in Campania, and at Gaul about the Pado (Po). The function of the fourth is not mentioned; perhaps it was Lillibecum in Sicily.

The etymology and original meaning of parricidium is doubtful. In the latter part of the word we have, of course, the same root as in the Latin pater, "father," and from the same root that we have in perperam, per-jurium, a moot point. Mommsen takes the latter view.

It is often supposed that the quaestores parricidii were an old magistracy quite distinct from the ordinary quaestors. For the identification of the two, see Mommsen, Römische Staatsrecht, ii, pt. I, p. 506.

1 Plutarch (De mortibus 12) states that the office was instituted by the first consul. Tacitus, on the other hand (Ann. xi. 22), says that it dated from the time of the kings, but his ground is merely that they were mentioned in the Lex Curialeta of the consul Brutus, which Tacitus assumes to have been identical with that of the kings.
QUAGGA—QUAIL

Literature.—For a fuller treatment of all these points see Mommens, Staatsrecht, ii, p. 525 foll.; for the existence of the quaestorship under the monarchy, and a different view of the second station of the Italian quaestors, see A. H. J. Greenidge, Roman Public Life, pp. 63, 215.

Quagga, or Couagga, an animal of the genus Equus (see Horse), nearly allied to Burchell’s zebra, formerly met with in vast herds on the great plains of South Africa between the Cape Colony and the Vaal river, but now completely extinct. Generally speaking, the colour of the head, neck, and upper-parts of the body was reddish-brown, irregularly banded and marked with dark brown stripes, stronger on the head and neck and gradually becoming fainter until lost behind the shoulder. There is a broad dark median dorsal stripe. The under surface of the body, the legs, and tail are nearly white, without stripes. The crest is very high, surmounted by a standing mane, banded alternately brown and white. It is, however, not improbable that there were two or more local races, for which separate names have been proposed. Though never really domesticated, quaggas have occasionally been trained to harness. The accompanying illustration is reduced from a painting made from one of two which were driven in Hyde Park by Mr. Sheriff Parkins in the early part of the 19th century. The name is an imitation of the shrill barking neigh of the animal, “ouag-ga, ouag-ga,” the last syllable very much prolonged; it is also commonly applied to the bonnie-quaggas, or Burchell’s zebra (see Horse and Zebra).

Quagmire, a bog or marsh, a piece of ground so saturated with water that it cannot support any weight. The word is composed of “qua” or “quack” (O.E. cwacian; cf. “quaver,” “quiver”) and “mire,” mud (Icel. myri, Swed. myr).

Skeat suggests that quag may be connected with the root seen in “quick,” and quotes (ETYm. DICT. 1898) Pieri Flouman, c, xxii, 64, of an earthquake, the earth “quok as it quyke were,” i.e., shook as if it were alive.

Quaich, or Quaigh, a form of Scottish drinking vessel. The word is an adaptation of the Gaelic caim, cup, bowl; cf. Welsh caug, and is usually referred to the Gr. καύσικος, καικός, through Lat. causus. In the 18th century it is sometimes spelled “quafr,” and a connexion has been suggested with “quaff,” to drink with a large or at a single draught; the New English Dictionary, however, considers this doubtful. The “quaich” was doubtless inspired by the low silver bowls with two flat handles, frequently used as bleeding vessels in England and Holland in the 17th century. The earliest quaiches were made of a solid block of wood, or of small staves of wood, often of different colours, supported by hoops, like barrels. They are generally fitted with two, and, more rarely, three short projecting handles. In addition to wood, they are made of stone, brass, pewter, horn, and of silver. The latter were often engraved with lines and bands in imitation of the staves and hoops of the wooden quaichs. The origin of these vessels in Scotland is traced to the Highlands; it was not until the end of the 17th century that they became popular in such large centres as Edinburgh and Glasgow. The silversmiths of such local gilds as Inverness and Perth frequently mounted them in silver, as may be seen from the hall-marks on the existing examples. They are found, of silver and pewter, in use as communion cups in various parts of Scotland; four, with the Edinburgh hallmark for 1722, belong to Ayr parish church; and a large one with the same hallmark for 1663–1684 is used as an alms-dish at Alvah, Banffshire. The loving cup at Donaldson’s hospital, Edinburgh, is a large silver quaich, with the Edinburgh stamp for 1724, which belonged to the founder of that hospital. The finest collection of these vessels is in the possession of the marquess of Breadalbane.

(E. A. J.)

Quail (O. Fr. Quaillle, Mod. Fr. Caille, Ital. Quaglia, Low Lat. Quaquina, Du. Kwakkel and Kwartel, Ger. Wachtel, Dan. Vogel), a well-known bird throughout almost all countries of Europe, Asia and Africa—in modern ornithology the Coturnix communis or C. domestica. This last epithet was given from the peculiar three-syllabled call-note of the cock, which has been grotesquely rendered in several European languages, and in some parts of Great Britain the species is popularly known by the nickname of “wet-my-lips” or “wet-my-feet.” The quail varies somewhat in colour, and the variation is rather individual than attributable to local causes; but generally the plumage may be described as reddish-brown above, almost each feather being transversely patched with dark brown interrupted by a longitudinal stripe of light buff; the head is dark brown above, with three longitudinal streaks of ochreous-white; the sides of the breast and flanks are reddish-brown, distinctly striped with ochreous-white; the rest of the lower parts are pale buff, clouded with a darker shade, and passing into white on the belly. The cock, besides being generally brighter in tint, not unfrequently has the chin and a double-throat band of reddish or blackish-brown, which marks are wanting in the hen, whose breast is usually spotted. Quails breed on the ground, and lay from nine to fifteen eggs of a yellowish-white, blotched and spotted with dark brown. Though essentially migratory by nature, not a few quails pass the winter in the northern hemisphere and even in Britain, and many more in southern Europe. In March and April they cross the Mediterranean from the south on the way to their breeding homes in large bands, but these are said to be as nothing compared with the enormous flights that emigrate from Europe towards the end of September. During both migrations immense numbers are netted for the market, since they are almost universally esteemed as delicate meat. The flesh of quails caught in spring commonly proves dry and indifferent, but that of those taken in autumn, especially when they have been kept long enough to grow fat, as they quickly do, is excellent. In no part of the British islands at present do quails exist in sufficient numbers to be the especial object of sport. In old days they were taken in England in a net, attracted thereto by a male-cailed, and simple instrument, the use of which is now wholly neglected—on which their notes are easily imitated. In South Africa and India allied species, C. delegorguii and C. coromandelica, the latter known as the Rain-Quail, respectively occur, as well as the commoner one, which in Australia and Tasmania is wholly replaced by C. pectoralis, the Stubble-Quail of the colonists. In New Zealand another species, C. novae-landiae, was formerly very abundant in some districts. Some fifteen or perhaps more species of quails, inhabiting the Indian and Australian regions, have been separated, perhaps unnecessarily, to form the genera Synnoca, Perdicula, Excalphator, and so forth.

America has some fifty or sixty species of birds which are commonly deemed quails, though by some authors placed in a distinct family or sub-family Odontophorinae. The best

1 One is figured in Rowley’s Ornithological Miscellany (ii, p. 363).
2 They form the subject of a monograph in folio by J. Gould, published between 1842 and 1860. See also S. D. Judd, Bulletin 27 of U.S. Dept. of Agriculture (1905); D. G. Elliot, Game Birds of North America (1897).
known is the Virginian Quail, or Colin, as it is sometimes called—that being, according to Hernandez, its old Mexican name. It is the Ortyx (or Colinus) tigrinus of modern ornithology, and has a wide distribution in North America, being called “partidge” in the Southern states, and elsewhere being known by the nickname of “Bob-White,” aptly bestowed upon it from a call-note of the cock. Many unsuccessful attempts have been made to introduce this bird to England (as indeed similar trials have been made in the United States with quails from Europe). The beautiful tufted Quail of California, Lophortyx Californica, has also been tried at large in Europe without success; but it is well established as an aviary bird. A few of the American Quails or Colin roost in trees.

Interesting from many points of view as is the group of birds last mentioned, there is another which, containing a score of species (or perhaps more) often termed Quails or Button-Quails, is of still greater importance in the eyes of the systematist. This is that comprehended by the genus Turchins, or Hemipodis of some authors, the anatomical structure of which removes it far from the genera Coturnix, Ortyx, and their allies, and even from any of the normal Gallinae. T. H. Huxley regarded it as the representative of a generalized stock from which the Charadriornathae and Alectorornathae, to say nothing of other groups, have sprung. The button-quails are now placed as a separate sub-order, Turchines, of the order Galliformes (see Bird). One species, T. sylectica, inhabits Barbary and southern Spain, and under the name of Andalucian Henipode has been included (though on evidence not wholly satisfactory) among British birds as a reputed straggler. The rest are natives of various parts of the Ethiopian, Indian and Australian regions. It is characteristic of the genus Turchis to want the hind toe; but the African Ortyxellus and the Australian Pedionomus, which have been referred to its neighbourhood, have four toes on each foot.

QUAIN, SIR RICHARD, Bart. (1816–1898), Irish physician, was born at Mallow-on-the-Blackwater, Co. Cork, on the 30th of October 1816. He received his early education at Clonny, and was then apprenticed to a surgeon-apothecary in Ballyhea. In 1837 he entered University College, London, where he graduated with high honours as M.B. in 1840, and as M.D. (gold medal) in 1842. Six years later he was chosen an assistant-physician to the Brompton Hospital for Diseases of the Chest, and with that institution he retained his connexion until his death, first as full (1853) and subsequently as consulting physician (1875). He became a fellow of the Royal College of Physicians in 1851, and filled almost every post of honour it could offer except the presidency, in the contest for which he was beaten by Sir Andrew Clark in 1888. He became physician-extraordinary to Queen Victoria in 1890, and was created a baronet in the following year. He died in London on the 13th of March 1898. Quain, who was elected a fellow of the Royal Society in 1871, was the author of several memoirs, dealing for the most part with disorders of the heart, but his name will be best remembered by the Dictionary of Medicine, the preparation of which occupied him from 1831 to 1893, and an act regulating the Levantine trade, which he sat on the Royal Commission on Rinderpest (cattle plague) in 1865.

He was a cousin of Jones Quain (1796–1865), the author of Quain’s Elements of Anatomy, and of Richard Quain (1800–1887), who was president of the Royal College of Surgeons in 1868, and left £7,500 to University College, London, with which the Quain professorships of botany, English language and literature, law, and physics were endowed. A half-brother of the last two, Sir John Richard Quain (1816–1876), was appointed a judge of the Queen’s Bench in 1877.

QUAIN (O. Fr. coine, from Lat. cognitus, known, probably influenced by association with Lat. compitus, near), an adjective meaning unusual or fanciful, often applied to things with a sense of old-fashioned charm or prettiness. “Querr,” which has much the same meaning, is of doubtful etymology, but is generally taken as adapted from Ger. quer, crooked.

QUAKERS, originally a cant name applied in derision to the members of the Society of Friends, but now used without any contemptuous significance. It was said to have originated in the saying of Justice Bennet at Derby in 1650, “Tremblor, or quake at the word of the Lord,” but it is now certain that it was used as early as 1647, and arose from the physical manifestations of religious emotion characteristic of many of the early Friends. (See FRIENDS, SOCIETY OF.)

QUANTUM MERUIT (Lat. for “as much as he has deserved”), in the law of contract, originally a form of action on the case, grounded on a promise to pay the plaintiff for work done as much as it was worth. It has been abolished as a special form of action, but the term is still in use where, in cases of special contract, there has been a breach amounting to a discharge by one party before the other party has done all that he was bound to do. In such a case the plaintiff sues for a quantum meruit or the value of so much as he has done.

QUARANTINE (Fr. quarantaine, a period of forty days), a term originally applied to the old sanitary preventive system of detention of ships and men-unloading of cargo in lazarets, fumigation of susceptible articles, &c., which was practised at seaports on account of the plague, in connexion with the Levantine trade. It is now a term of the law. It was created in 1531, the great lazard of that city, perhaps the most complete of its kind, having been founded in 1526 on the island of Pomègue. The practice at all the Mediterranean lazarets was not different from the English procedure in the Levantine and North-African trade. On the approach of cholera in 1831 some new lazarets were set up at western ports, notably a very extensive establishment near Bordeaux, afterwards turned to another use.

The plague had disappeared from England, never to return, for more than thirty years before the practice of quarantine against it was definitely established by an act of Parliament of Queen Anne’s reign (1710). The first act was called for, owing to an alarm lest plague should be imported from Poland and the Baltic; the second act of 1751 was due to the disastrous prevalence of plague at Marseilles and other places in Provence; it was renewed in 1773 owing to a fresh outbreak of the malady on the continent of Europe, and again in 1743 owing to the disastrous epidemic at Messina. In 1752 a rigorous quarantine clause was introduced into an act regulating the Levantine trade; and various arbitrary orders were issued during the next twenty years to meet the supposed danger of infection from the Baltic. Although no plague cases ever came to England all those years, the restrictions on traffic became more and more stringent (following the movements of medical dogma), and in 1788 a very oppressive Quarantine Act was passed, with provisions affecting cargoes in particular. The first year of the 19th century marked the turning-point in quarantine legislation; a parliamentary committee sat on the practice, and a more reasonable act arose on their report. In 1805 there was another new act, and in 1823–24 again an elaborate inquiry followed by an act making the quarantine only at discretion of the privy council, and at the same time recognizing yellow fever “or other highly infectious disorder” as calling for quarantine measures along the coast.

1 The strict sense of the term is also preserved in the “widows’ quarantine,” the right of a widow to remain in the principal house belonging to her husband for forty days after his death.
with plague. The steady approach of cholera in 1831 was the last occasion in England of a thoroughgoing resort to quarantine restrictions. The pestilence invaded every country of Europe despite all efforts to keep it out. In England the experiment of hermetically sealing the ports was not seriously tried when cholera returned in 1849, 1853 and 1865-66. In 1847 the privy council ordered all arrivals with clean bills from the Black Sea and the Levant to be admitted to free pratique, provided there had been no case of plague during the voyage; and therewith the last remnant of the once formidable quarantine practice against plague may be said to have disappeared.

For a number of years after the passing of the first Quarantine Act (1710) the protective practices in England were of the most haphazard and arbitrary kind. In 1721 two vessels laden with cotton goods, &c., from Egypt, were a case of plague, were ordered to be burned with their cargoes, the owners receiving £3,933 as indemnity. By the clause in the Levant Trade Act of 1752 vessels for the United Kingdom with a full bill (i.e. coming from a country where plague existed) had to repair to the lazarets of Malta, Venice, Messina, Leghorn, Genoa or Marseilles, to perform their quarantine or to have their cargoes "sufficiently opened and aired." Since 1741 Stangate Creek (on the Medway) had been made the quarantine station at home; but it would appear from the above clause that it was available only for vessels with clean bills. In 1755 lazarets in the form of floating hulks were established in England for the first time, the cleansing of cargo (particularly by exposure to dew) having been done previously on the ship's deck. There was no medical inspection employed, but the whole routine left to the officers of customs and quarantine. In 1786, when plague was in Poland, even vessels with grain from the Baltic had to lie forty days in quarantine, and unpack and air the sacks; but owing to remonstrances, which came chiefly from Edinburgh and Leith, grain was from that date declared to be a "non-susceptible article." About 1788 an order of council required every ship liable to quarantine, in case of meeting any vessel at sea, or within four leagues of the coast of Great Britain or Ireland, to hoist a yellow flag in the daytime and show a light at the maintopmast head at night, under a penalty of £200. After 1800, ships from plague-countries (or with foul bills) were enabled to perform their quarantine on arrival in the Medway instead of taking a Mediterranean port on the way for that purpose; and about the same time an extensive lazaret was built on Chetney Hill near Chatham at an expense of £170,000, which was almost at once condemned owing to its marshy foundations, and the materials sold for £15,000. The use of floating hulks as lazarets continued as before. In 1800 two ships with hides from Mogador (Morocco) were ordered to be sunk and their cargoes at the Nore, the owners receiving £15,000. About this period it was merchandise that was chiefly suspected: there was a long schedule of "susceptible articles," and these were first exposed on the ship's deck for twenty-one days or less (six days for each installment of the cargo), and then transported to the lazaret, where they were opened and aired forty days more. The whole detention of the vessel was from sixty to sixty-five days, including the time for repARATION of her cargo. Pilots had to pass fifteen days on board a "convalescent ship." The expenses may be estimated from one or two examples. In 1820 the "Asia," 753 tons, arrived in the Medway with a foul bill from Alexandria, laden with linseed; her freight was £475 and her quarantine dues £620. The same year the "Platino," 498 tons, making the same voyage, paid £200 quarantine dues on a freight of £1000. In 1823 the expenses of the quarantine service (at various ports) were £26,690, and the dues paid by ships (nearly all with clean bills) £2,200. A return for the United Kingdom and colonies in 1847 showed, among other details, that the expenses of the lazaret at Malta for ten years from 1839 to 1848 had been £53,553. From 1846 onwards the establishments in the United Kingdom were gradually reduced, while the last vestige of the British quarantine law was removed by the Public Health Act 1866, which repealed the Quarantine Act 1825 (with dependent clauses of other acts), and transferred from the privy council to the Local Government Board the powers to deal with ships arriving infected with yellow fever or plague, the powers to deal with cholera ships having been already transferred by the Public Health Act 1825.

The existing British regulations are those of 9th November 1866; they apply to yellow fever, plague and cholera. Officers of the Customs, as well as of Coast Guard and Board of Trade (for signalling), are empowered to take the initial steps. They certify in writing the departure of a suspect ship, and have the power provisionally for not more than twelve hours, giving notice meanwhile to the port sanitary authority. The medical officer of the port boards the ship and examines every person in it. Every person is placed under quarantine, and kept under the orders of the medical officer. If the sick cannot be removed, the vessel remains under his orders. Every person suspected (owing to his or her history, symptoms of infection, or any other cause) is under quarantine, and must be kept under the observation for a few days. The ship is disinfected, dead bodies buried at sea, infected clothing, bedding, &c., destroyed or disinfected, and all persons and goods coming in contact with dead bodies, infected persons or anything which might be infected, are subject to quarantine. The owners are guaranteed in the case of shipwreck and all the cargoes are subject to no detention. A stricken ship within 3 miles of the shore must fly at the main a yellow and black flag borne quarterly from sunrise to sunset.

International Conventions.—Since 1852 several conferences have been held between delegates of the Powers, with a view to uniform action in keeping out infection from the East and preventing its spread within Europe; all but that of 1897 were occupied with cholera. No result came of those at Paris 1852, Constantinople 1866, Vienna 1874, and Rome 1885, but each of the subsequent ones has been followed by an international convention on the part of nearly one-half of the Powers represented. In 1858, the general effect of the high quarantine doctrine of "constructive infection" as a ship was coming from a scheduled port, and an approximation to the principles advocated by Great Britain for many years. The principal States which retain the old system are Spain, Portugal, Turkey, Greece and Russia (the British possessions Gibraltar, Malta and Cyprus being under the same influence). The aim of each international sanitary convention has been to bind the Powers to a uniform minimum of preventive action, with further restrictions permissible to individual States. The minimum is now very nearly the same as the British practice, which has been in turn adapted to continental opinion in the matter of the importation of rags.

The Venice convention of 1852 was on cholerá by the Suez Canal route; that of Dresden, 1863, on cholera within European countries; that of Paris, 1874, on cholera were not attended. That of Vienna, 1897, was in connexion with the outbreak of plague in the East, and the conference met to settle on an international basis the steps to be taken to prevent, if possible, its spread into Europe. Several of the rights and liabilities of the ship were settled, and it was decided that the incubation period for this disease, and the period to be adopted for administrative purposes. It was admitted that the incubation period was, as a rule, a comparatively short one, namely, of some three or four days. After its period of incubation is over, it is accepted by a very large majority. The principle of notification was unanimously adopted. Each Government is to notify to other Governments the existence of plague within their jurisdiction, and if notified at such a distance as to prevent the disease from being carried thither, which are being carried out to prevent its diffusion. The area to be infected is limited to the actual district or village where the disease prevails, and no locality is to be deemed infected merely because of the importation into it of a few cases of plague while there has been no diffusion of the malady. As regards the precautions to be taken on land frontiers, it was decided that during the prevalence of plague every country had the right to close its ports, and that after closing them for forty-eight hours. As regards the Red Sea, it was decided after discussion that a healthy vessel may pass through the Suez Canal, and continue its voyage in the Mediterranean during the period of incubation of the disease the prevention of which is the object of quarantine. It was also decided that the Canal in quarantine might, subject to the use of the electric light, coal in quarantine at Port Said by night as well as by day, and that passengers might embark in quarantine at that port. Infected vessels, if these carry a doctor and are provided with a disinfecting stove, have a right to navigate the Canal in quarantine, subject only to the landing of those who are suffering from plague, and of
such persons as have been in actual contact with the sick or with infected articles, together with the disinfection of the infected compartment of the vessel. Passing on to the conclusions dealing with regulations to be imposed "in Europe," the following are the chief points that may be noted. As regards measures to be adopted at ports of arrival, the conclusions of the Dresden convention were far more practical. In the case of healthy vessels, i.e., those on board of which there is no illness, though they have sailed from an infected port, it was decided that the vessel and its crew once free have pratique, but at the option of the local authority certain measures of disinfection of soiled articles may be required. For suspected vessels, viz., those on board of which there has been plague, or any person with plague, it was decided that the vessel and its cargo be isolated under the quarantine, and that the measures of disinfection, &c., as defined, having been complied with, it is recommended that the crew and passengers should be subject to surveillance for a period of ten days from the date of the arrival of the vessel. When infected, viz., when the disease is present, if the plague is actually present, or on which that disease has occurred ten days before arrival, the sick are to be landed and isolated, and the remainder of those on board are to be subjected, at the discretion of the local authority, "to observation" or "surveillance," for a period not exceeding ten days from the date of the occurrence of the last case of plague. In this convention the terms "observation" and "surveillance" are for the first time clearly defined, the definitions as to the latter stating that under that system passengers are not to be isolated, but are to be allowed at once to proceed to their homes, where they can remain under medical supervision for a period as may be deemed necessary by the local authority. The results of the convention are that it indicates the need for an advance towards the nationalities represented towards a liberal and truly scientific conception of the means to be adopted by their respective Governments for the prevention and control of infective diseases.

Library Catalogue of the Science Association collected, in 1860-61, valuable consular returns on the practice of quarantine in all parts of the world; these were edited by Milroy and ordered to be printed (with the report and summary) as the "Quarantine Reports," and to be published "annually." The third paper (6th August 1861, No. 544) contains, in an appendix, an Historical Sketch of Quarantine Legislation and Practice in Great Britain, by Dr Milroy. Russell's Treatise on the Plague (to, London, 1791) contains remarks on quarantine of ships, &c., and an account of the mode of "shutting up" practised by householders in Aleppo on the outbreak of plague in the town. The inexpediency of quarantine in the United Kingdom is discussed by John Simon in the Report of the Medical Officer of the Privy Council for 1865, p. 35, and also in the Report (Medical Department Board, xxiv. 1892-93).

**QUARE IMPEDIT,** in English law, a form of action by which the right of presentation to a benificer is tried. It is so called from the words of the writ formerly in use, which directed the sheriff to command the person disturbing the possession to permit the plaintiff to present a fit person, or to show cause "why he hinders" the plaintiff in his right. The action was one of the few real actions preserved by the Real Property Limitation Act 1833, and survived up to 1860. The effect of the Common Law Procedure Act 1860, § 26, was to assimilate proceedings in quare impedit as far as possible to those in an ordinary action. It is now usually brought against a bishop to try the legality of his refusal to institute a particular cleric. The bishop must fully state upon the documents which he refuses. Quare impedit is peculiarly the remedy of the patron; the remedy of the cleric is the proceeding called duplex querela in the ecclesiastical court. The action is not barred till the expiration of sixty years, or of three successive incumbencies adverse to the plaintiff's right, whichever period be the longer (Real Property Limitation Act, 1833, § 29). Where the patron of a benefice is a Roman Catholic, one of the universities presents in his place (1689, 1 Will. & Marv, sess. 1, c. 29). By 13 Anne c. 13 (1714), during the pendency of a quare impedit to which either of the parties is in right of the patron being a Roman Catholic, the court has power to administer an oath for the discovery of any secret trust, and to order the custos quae trust to repeat and subscribe a declaration against transubstantiation. In Scotland the effect of a quare impedit is attained by action of declarator. In the United States of America, by the difference of ecclesiastical organization, the action is unknown.

**QUARITCH, BERNARD** (1810-1899), English bookseller and collector, was born at Worbs, Germany, on the 23rd of April 1819. After being apprenticed to a bookseller, he went to London in 1842, and was employed by Bohn the publisher. In 1847 he started a bookseller's business off Leicester Square, becoming naturalized as a British subject. In 1858 he started to issue a monthly Catalogue of Foreign and English Books. About 1858 he began to purchase rare books, one of the earliest of such purchases being a copy of the Masarae Bible, and within a period of forty years he possessed six separate copies of this rare and valuable edition. In 1860 he removed to Piccadilly. In 1873 he published the Bibliotheca Xylographica, Typographica et Palaeographica, a remarkable catalogue of early productions of the printing press of all countries. He became a regular buyer at all the principal book-sales of Europe and America, and from time to time to publish a variety of other catalogues of old books. Amongst these may be mentioned the Supplemental Catalogue (1874), and in 1880 an immense catalogue of considerably over 2000 pages. The last complete catalogue of his stock was published in 1887-88 under the title General Catalogue of Old Books and Manuscripts, in seven volumes, including under various sub-sections supplements to two. All these catalogues are of considerable bibliographical value. By this time Quaritch had developed the largest trade in old books in the world. Among the books that he published was Fitzgerald's Omar Khayyam, and he was the agent for the publications of the British Museum and the Society of Antiquaries. He died at Hampstead on the 17th of December 1899, leaving his business to his son.

**QUARLES, FRANCIS** (1592-1644), English poet, was born at Romford, Essex, and baptized there on the 8th of May 1592. His father, James Quarles, held several places under Elizabeth, and traced his ancestry to a family settled in England before the Conquest. He was entered at Christ's College, Cambridge, in 1608, and subsequently at Lincoln's Inn. He was made cupbearer to the Princess Elizabeth, Electress Palatine, in 1613, remaining abroad for some years; and before 1620 he was appointed secretary to Ussher, the primate of Ireland. About 1627 he returned to England, and spent the next two years in the preparation of his Emblems. In 1633 he was made city chronicler, a post in which Ben Jonson and Thomas Middleton had preceded him. At the outbreak of the Civil War he took the Royalist side, drawing up three pamphlets in 1644 in support of the king's cause. It is said that his house was searched and his papers destroyed by the Parliamentarians in consequence of these publications. He died on the 8th of September in that year.

Quarles married in 1618 Ursula Woodgate, by whom he had eighteen children. His son, John Quarles (1624-1665), was exiled to Flanders for his Royalist sympathies and was the author of Pons Lachrymarum (1648) and other poems.

The work by which Quarles is best known, the Emblems, was published originally in 1635, with grotesque illustrations engraved by William Marshall and others. The forty-five prints in the first seven books of the Emblems are by the poet Desiderius (Antwerp, 1624) of Herman Hugo. Each "emblem" consists of a paraphrase from a passage of Scripture, expressed in ornate and metaphorical language, followed by passages from the Christian Fathers, and concluding with an epigram of four lines. The Emblems was immensely popular with the vulgar, but the critics of the 17th and 18th centuries had no mercy on Quarles. Sir John Suckling in his Sessions of the Poets respectfully alluded to him as "that makes God speak so big in his poetry." Pope in the Dunciad spoke of the Emblems, "Where the pictures for the page atone.

And Quarles is saved by beauties not his own."

The works of Quarles include: A Poem of the History of Jonah (1620), which contains other scriptural paraphrases besides the one that furnishes the title: Hadassah, or the History of Queene Ester (1621); Job Military, with Meditations Divine and Morall (1624); Sonets Elegies, etc. by Jeremy the Prophet (1624); Sonets Sonnets sung by Solomon the King (1624), a paraphrase of Ovid's Carmina; The History of Sampson (1631); Alphabet of Elegies upon ... Dr Aymer (1652); Argalus and Parthenia (1629), a subject of which is borrowed from Sir Philip Sidney's Arcadia; four books of Divine Poems digested into Epigrams, Meditations and Observations (1629); a reissue of his scriptural paraphrases and the Alphabet of Elegies as Divine Poems (1633): Hieroglyphics.
of the Life of Man (1638); Encycyclion, containing Institutions Divine and Moral (1640–41), a collection of four "centuries" of miscellaneous aphorisms; Observations concerning Princes and States upon Peace and War (1642), and Beanerges and Barnabes—Wine and Dyke. Anathematized (1644–46), both of which are collections of miscellaneous reflections; three violent Royalist tracts (1644). The Loyall Convert, The Whisper Whisp, and The New Distanties, reissued in one volume in 1645 with the title of The Prefatory, Religious, Moral, and Geographical Works of Solomon's Querelles (1645) contains a memoir by his widow. Other posthumous works are The Shepheards' Oracles (1646), a second part of Beanerges and Barnabes (1646), a broadside entitled A Direful Armageddon against Peace-lovers (1647), and an interlude, The Virgin Widow (1649).

An edition of the Emblems (Edinburgh, 1857) was embellished with new illustrations by C. H. Bennett and W. A. Rogers. These are more or less complete copies of those contained in a volume in the "Chertsey Worthies Library" by Dr. B. Grosart, who provides an introductory memoir and an appreciation which greatly overestimates Quarles's value as a poet.

**QUARREL.** (1) Through Fr. querelle from Lat. querela, complaint), originally a complaint against a person, particularly a legal accusation or charge, hence a ground or cause for complaint or anger, or, more generally, an outbreak of anger or violent dispute. (2) Through O. Fr. quarrel or quarell, from med. Lat. quadrellum, diminutive of quadrus, square), a heavy short bolt or arrow with a square head, used in a cross-bow or arbalist. In architecture this term (and also the doublet "quarry") is applied to any square-shaped opening, in the Beauchamp Roll to the quatrefoils in Perpendicular windows, sometimes to squares of paving, but most commonly to the lozenge-shaped pieces of glass in lead casements (see Glass, Stained).

**QUARRY.** (1) Through Fr. from med. Lat. quarta or quadraria, or square or new stone), a place from which stones are dug, the term being usually confined to a place where such operation is carried on in the open air, as opposed to a "mine" (see Quarrying). (2) Through O. Fr. cuire, cuir, skin, leather, Lat. curtium; cf. mod. Fr. cuire, spoils), properly certain parts of a deer or other beast of chase given as a reward to the hounds and placed upon the hide of the animal, also parts of a bird given similarly to a hawk or falcon. The word is thus applied to the animal hunted or the bird killed by the hawk, and generally to any object of the chase.

**QUARRYING.** The art of winning or obtaining from the earth's crust the various kinds of stone used in construction, the operation being, in most cases, conducted in open workings. According to their composition, building stones are broadly classed as granites, sandstones, limestones and slates. Under the first of these heads is included a number of crystalline rock species, such as granite, syenite, gneiss, &c., which to the geologist are quite distinct, but which in commerce are all spoken of as granite. They are chiefly composed of one or more minerals of the felspar group mingled with one or more of the micas or hornblende, and usually contain quartz. Sandstones are chiefly composed of fragments of quartz cemented into solid rock by silica and oxide of iron. Of these there are many varieties, including flagstone used for foot-pavements. Limestones consist principally of carbonate of lime. Their chief variations are the crystalline form known as marble and the deposit from mineral springs known as Mexican onyx. Slates are mudstones or shales hardened by heat and pressure, and rendered fissile by the latter agent. Chemically they consist chiefly of hydrous silicate of alumina. Theoretically, granites are massive, and have no bedding or stratification like sandstones and limestones; but all rock masses are usually found to be more or less shattered by movements of the earth's crust which occur as a result of its constant, readjustment to the cooling and shrinking interior, so that the rocks are divided by cracks or fissures, which are commonly known as joints. In the massive granites these joints, which usually occur in two or more planes at right angles to one another, are of the greatest importance to the quarryman, as they enable him to separate masses of stone with approximately parallel faces. In gneisses the parallel arrangement of the minerals usually coincides with a direction of easy cleavage, known to quarrymen as the "rift"; at right angles to this direction is usually one less easy parting, known as the "grain." Sandstones and limestones are stratified rocks which have been formed as sediments in bodies of water; and whether their beds are found in the normal position of horizontality, or whether they have been tilted and folded by earth movements, the direction of easiest separation is coincident with the original planes of sedimentation and parallel to them. This is therefore called the "rift," while the "grain" is at right angles to it. In gneisses, sandstones and limestones joints also occur; and while more convenient for the division of the beds into masses of useful size, they may be a detriment, as when they occur close together as to fall within the limits of a block available for commercial purposes. In commerce the various kinds of building stone are usually designated by the name of the locality or region in which the quarry is situated. In the case of the more important varieties this geographic name usually connects to the archway or builder full information concerning the colour, texture and other properties of the material. For example, the names Hallowell or Quincy granite, Medina or Berea sandstone, and Vermont or Tennessee marble, convey in the United States full information to those interested.

The methods of quarrying vary with the composition and hardness of the rocks, their structure, cleavage, and other physical properties; also with the position and character of the deposits or rock-masses. The general purpose of the work is to separate the material from its bed in masses of form and size adapted to the intended use. Cutting the stone to accurate dimensions, dressing, rubbing and polishing are subsequent operations not involved in quarrying.

The practice of quarrying consists in uncovering a sufficient surface of the rock by removing superficial soil, sand or clay, or by sinking a shaft or slope, and then with proper tools and, when necessary, with explosives, detaching blocks of form and size adapted to the purpose in view. Frequently the outer portion of the rock has been affected by the action of the weather and other atmospheric agencies, so that it has become discoloured or softened by decay. This weathered material must be removed before stone can be obtained for use. A quarry should, if possible, be opened on a hillside, for in this case it is usually much easier to dispose of the water which necessarily collects in any deep excavation, and which, if drainage by gravity is not afforded, must be removed by pumping, at considerable expense. As it is generally most convenient to operate on a vertical face of rock, the preliminary work of opening a quarry is usually directed toward the production of this result; but its accomplishment involves the waste of a certain amount of stone, which must be broken into irregular and useless pieces. The separation of blocks of building stone is effected ordinarily by drilling holes along the outlines of the block to be removed, and then, by exploding blasting-powder in the holes, or by driving wedges into them, exerting sufficient force to overcome the cohesion of the rock and rend it asunder. In many quarries it is found most convenient to separate a large mass and afterwards divide it into blocks of the required size. When the rock is stratified, or has an easily determined "rift," the holes are drilled at right angles to the plane of separation. When there is no stratification or "rift," or these natural planes of separation are too far apart, or when the position of the joints is not disadvantageous, a row of horizontal holes must be drilled into the face or "breast" of the quarry, along which separation is effected by the use of wedges. Of late at certain American quarries, in a granite which has no rift or direction of ready cleavage, compressed air has been brought into service to effect the separation of extensive layers. A hole is drilled as deep as the desired thickness of the layer to be divided, and a small charge of dynamite is exploded at the bottom of it. This develops a cavity in which a small charge of powder is next exploded, producing a crack or crevice parallel to the surface of the rock. A pipe for conveying compressed air is now sealed into the opening, and gradually increasing pressure is introduced. This results in the gradual extension of the crevice developed by...
the explosion of the powder. In the absence of compressed air, water under pressure may be used and also small powder charges exploded at intervals of a few days. In thinly bedded sandstones, where vertical joints are frequent, it is often possible to separate the desired slabs and flagstones with crowbars and wedges, without drilling or the use of explosives. When blasting is necessary, some form of gunpowder is generally used, rather than a violent explosive like dynamite, in order to avoid shattering the rock. This, however, applies only to dimension stone.

When the production of broken stone for road-making, concrete, or similar purposes is the sole end in view, violent explosives are preferred. In limestones and marbles and in the softer sandstones, channelling machines, driven by steam, are employed, by which vertical or oblique grooves or channels can be cut with great rapidity to a depth of several feet. A level bed of rock is cleared, and on this are laid rails, along which the machine moves. After the channels are cut, a row of holes is bored perpendicularly to the former at the desired distance below the surface of the bed, and by driving wedges into these the required blocks are separated.

When the beds of stone to be quarried are thin, and when to remove the whole of the overlying mass of earth or rock would be too expensive, it is found convenient to treat the quarry as if it were a mine, and to rely upon methods similar to those practised in mining. A horizontal bed of rock is usually opened at its outcrop on some hillside, or if this is impracticable, as shaft or slope is excavated to reach it. If dimension stone is required, a deep horizontal groove is cut near the top or the bottom of the bed. The quarry face is then divided into blocks by saw cuts, channels, or rows of drill-holes, and the blocks are separated by wedging or blasting. As the excavation or stoping progresses, portions of the rock are left in place as pillars to support the roof. At many localities in Europe where quartzite is quarried, it is found in beds dipping more or less from the horizontal. These deposits are worked by stopes which follow the inclination of the bed, from which, at convenient intervals, levels are driven across, to take advantage of the cleavage of the slate. As in other subterranean quarries, pillars of rock are left to support the roof, since artificial supports would be more expensive. At some of the marble quarries in Vermont, U.S.A., where the strata are very nearly vertical, the beds are worked to a great depth with a comparatively small surface opening.

See G. P. Merrill, Stones for Building and Decoration (New York, 1896); C. Le N. Foster, A Text-book of Ore and Stone Mining (London and Philadelphia, 1894); O. Herman, Steinbruchindustrie und Steinbrechgeologie (Berlin, 1896).

QUARTER (through Fr. from Lat. quartarius, fourth part), a word with many applications of its original meaning, namely, one of the four divisions of anything; thus as a measure of weight a quarter is 28 lb, one-fourth of the hundredweight of 112 lb; as a measure of capacity for grain it equals 8 bushels; similarly in liquid measure the shorter form "quart" is a quarter of a gallon = 2 pints, so "quartern" is a quarter of a pint (a gill), or, as a measure for bread, 4 lb. "Quarter" is also used of the fourth part of the moon's monthly revolution, and of a fourth part of the legal year, marked off by the "quarter-days" (see below). For the division of the heraldic shield into four "quarters" and the use of the term "quartering," the marshalling of several coats on one shield, see HERALDRY. From the four principal points of the compass and the corresponding division of the horizon, &c., the word is used generally of direction or situation, and hence of a district in a town, &c., especially when assigned to or occupied by a particular class. It has thus become the usual term applied to stations, buildings, lodgings, &c., in the regular occupation of military troops (see Barracks, Camp, and CANTONMENTS).

There are some technical uses of the word, in which the original meaning has been lost or obscured; thus in carpentry and architecture it is applied to the main upright posts in framing, sometimes called "studs"; the filling in quarters were formerly named "pock posts"; in farriery, to one side of the "cofin" of a horse's foot; in bootmaking, to the side piece of leather reaching from the vamp to the heel. The "quarter" of a ship is the after part of her side from the mainchains to the stern (see QUARTERDECK).

There has been much discussion as to the origin of the use of the word "quarter" in the sense of mercy, clemency, the sparing of the life of a beaten enemy and the acceptance of his surrender. The same use is found in Fr. quarter. Cosgrave explains this word as a "fair war," when soldiery are taken prisoners and ransomed at a very moderate rate, "as cannot be, as has often been repeated, following De Brieux (Origines de plusieurs façons de parler, 1672), that it was due to a supposed agreement between the Dutch and Spaniards for ransoming officers and men at one quarter of the ordinary price. The word is used for the "quarters," i.e. lodgings, to captured prisoners whose lives were spared, or the use of the word, now obsolete, for relations with or conduct towards another, in the sense of fair treatment; thus in Bacon's Essay in Cawring, "two, that were competitors,. . . kept good quarter between themselves."

Quarter days are the days that begin each quarter of the year. In England they are the 25th of March (Lady Day), the 26th of June (Midsummer Day), the 31st of September (Michaelmas Day), and the 31st of December (Christmas Day). They are the days on which it is usually contracted that rents should be paid and houses or lands entered upon or quitted. In Scotland there are two quarter days, the 28th of May (Lammas) and the 24th of November (Martinmas); these, together with the two conventional terms, 2nd of February (Candlemas) and the 1st of August (Lammas), make up the Scottish quarter days. In the Scotch burghs, however, the conventional terms are the 28th of May and the 28th of November. In the United States the quarter days are, in law, the 1st of January, April, July and October.

QUARTERDECK, the after part of the upper deck of a ship. In former times the upper deck of a line-of-battle ship or frigate ended at the mainmast, and was connected with the forecastle by two narrow passages, or gangways running along the sides. The quarterdeck is the residence and symbol of authority in a warship. The starboard, or right side looking forward, is reserved to the senior officer. A sailor who had a complaint to make was said to come to the mainmast, because he placed it (the mainmast) at the forward end of the quarterdeck near the mast. According to the ancient custom of the sea, the quarterdeck is to be saluted by all who come upon it, and the salute is returned by all officers present.

QUARTER SESSIONS, COURT OF, in English law, the name for the justices of the peace of any county, riding parts, division or liberty of a county, or of any county of a city or county of town, in general or quarter sessions assembled; it includes the court of the recorder of a municipal borough having a separate court of quarter sessions. The word "general" in this context is contrasted with "special" or "petty." The court is a local court of record having a limited criminal jurisdiction, and also to some extent civil jurisdiction. As a court of record it has, in addition to its other jurisdiction, power to punish summarily without the assistance of a jury contemns committed in its presence, such as insults to the justices or disturbance of its proceedings. At the present time the whole of England and Wales is within the local jurisdiction of some court of quarter sessions. But the history of the court in counties is quite distinct from its history in boroughs.

Counties.—As regards counties the court originated in statutes of 1326, 1344, and 1350, which provided for justices in counties, and the commission of the peace. The court derived its name from the direction in a statute of 1358 that the "justices shall keep their sessions in every quarter of the year at the least." By a statute of 1414 they were directed to make their sessions four times in the year: that is to say, in the first week after the feasts of St. Michael, the Epiphany, the clause of Easter and the translation of St Thomas the Martyr, and more often if need be. These dates have only been slightly varied, first in 1814 in consequence of the adoption of the Gregorian calendar, later in 1830 by specifying the first week after the 11th of October, 28th of December, 21st of March and 24th of June respectively, instead of the church feasts; and in 1894 by

An earlier statute not repealed (36 Edw. III. c. 12) fixes the third and fourth sessions differently, viz. second week of mid-Lent, and between Whit Sunday and Mid-Lent Day.
giving the justices a limited power of fixing their sessions so as not to clash with the assizes. It will be seen that the statutes do not limit the justices to four sessions a year: and they are free to sit oftener by adjournment of the quarterly sessions to another time, and even to another place, in their county, or to hold additional sessions. All the sessions thus held are "general," though not all may be "quarter" sessions. The Assizes and Quarter Sessions Act 1908 gave the useful power of dispensing with the holding of quarter sessions if there is no business to transact.

**Constitution of the Court.**—Such a court sits for every judicial county in England, and is composed of two or more of the justices in the commission of the peace for the county, including ex officio justices for the division in which the court is held, and consists in the hands of the justices at two. At one time certain specified justices described as of the quorum must be present, but under the present commission there are no such persons. In certain counties more than one commission of the peace is held, e.g., for the three ridings of Yorkshire (N.E. and W.) and the liberty of Ripon, the three parts of Lincolnshire (Lindsey, Kesteven and Holland), the isle of Ely and the rest of Cambridgeshire, the soke of Peterborough, and the rest of Northamptonshire, &c. or the whole of London, the justices in the commission elect a chairman and vice-chairman, neither of them necessarily a lawyer, to preside at the sittings of the court. In the county of London there are a paid chairman and vice-chairman. In other counties the chairman has served ten years' standing, and are appointed by the crown. There is special legislation as to quarter sessions in the county palatine of Lancaster; and in the Salford Hundred of that county there is a paid chairman. The chairman is also the official records officer. Arrangements have been made by which in Sussex and Suffolk the quarter sessions for the eastern and western divisions are virtually distinct courts. Under the Quarter Sessions Act 1888 the court may sit in two divisions of at least two justices at the same time and place, but not simultaneously in separate parts of the same county, except under statutory authority as in London.

The court may sit while the assizes for the county are being held, but usually refrains from doing so because of the inconvenience which would be occasioned, and adjusts its sittings as to avoid clashing with the assizes. The chief officer of the court is the clerk of the peace, who acts as clerk to the court, records its proceedings, calls and swears juries, &c. The clerk draws many of the indictments, receives the bills returned by the grand jury, arraigns the prisoners and taxes the costs. In a county he is appointed by a standing joint-committee of the quarter sessions and the county council, and has charge of, and responsibility for, the records and documents of the county subjudice, and is also in charge of the petty sessions. In boroughs the sessions or the county council (Local Govt. Act 1888, s. 83).

**Boroughs.**—The jurisdiction of the court of quarter sessions of a borough does not depend upon the commission of the peace, but upon the Municipal Corporations Act 1882. Many boroughs have a separate commission of the peace (which does not contain the words of the county commission giving jurisdiction to try indictments), but have not received the grant of a separate court of quarter sessions: and such boroughs are within the jurisdiction of the quarter sessions of the county for the county within which the borough lies. Before the Municipal Corporations Act 1835, many boroughs had criminal jurisdiction under their charters. Under that act and the act of 1852 a grant of quarter sessions to a city or borough is made by the crown in petition of the urban council. The recorder, a subscriber of not more than ten years' standing appointed by the crown, is the sole judge of the court, though the mayor can adjourn it in the absence of the recorder; he has a discretion to fix his own dates for the holding of the court, so long as he holds it once in every quarter of a year; and it may be held more frequently if he think fit, or a secretary of state so directs; he has no power to allow, apportion, make or levy a borough rate or to grant a licence for the sale of excisable liquors by retail; a deputy may be appointed by the recorder, or in the event of his being unable to make the appointment by a secretary of state. Subject to these qualifications the court has the same jurisdiction as county quarter sessions.

The city of London is not subject to the Municipal Corporations Act 1832, and its court of quarter sessions is created by the city charters, and is held before the mayor and aldermen with

1 In the soke of Peterborough, commissions of arrest and assize, and gaol delivery, as well as a commission of the peace, are issued.

**Criminal Jurisdiction, Original.**—Courts of quarter sessions in counties and boroughs have both original and appellate jurisdiction depending on the commission of the peace and on legislation beginning in 1844. The jurisdiction is derived from the commission of the peace, which directs the justices "to inquire the truth more fully by the oath of good and lawful men of the county, by whom the truth of the matter shall be better known of all manner of persons accused before them, in the county, of which the justices of our peace may or ought lawfully to inquire," and "to hear and determine all and singular the crimes, trespasses and offences aforesaid." According to the laws and statutes of our predecessors, the determination of any of the premises before you shall happen to arise then let judgment in no wise be given "unless in the presence of one of the justices of assize for the county." This proviso has been modified by the Lord Mayor, the recorder and the justices for trial at the assizes, or to transmit to assizes indictments found at quarter sessions which raised difficult questions. Quarter sessions never dealt with forgery or perjury, but at one time assumed jurisdiction over all civil actions. Quarter Sessions Act 1842 and subsequent legislation, they are forbidden to try the following offenses: treason or misprision of treason; murder, capital felony or any felony (except burglary) which is punishable by a fine of three thousand pounds; forgery and false pretenses to the value of one hundred pounds; money-lending; illegal assizes or juries; procedures against any of the House of Parliament; offenses against the Official Secrets Act 1889; offenses subject to the penalties of praemunire; certain offenses against religion and opinion, and composing or publishing blasphemous seditionary or seditious libels; administering and taking unlawful oaths; perjury and subornation and making or suborning another to make a false oath, declarations or affirmations punishable as perjury or as a misdemeanour; abduction of women and girls; and offenses under the Criminal Law Amendment Act 1885; bigamy and offenses against the laws of marriage; concealment of birth; bribery and corruption at elections or of agents or public officials (but they can try offenses against the state); offenses against the peace of the realm; offenses in woods and heaths; stealing or destroying certain classes of documents; offenses against the factor sections (ss. 75-85) of the Larceny Act as amended by the Larceny Act 1901; and conspiracies to commit offenses against the queen. Trials before the court are governed by the same procedure as trials on indictment in a court of assize. Under the Vagrancy Act 1823 and amended acts, they have special powers to order and control the taking of fingerprints under a special criminal jurisdiction, and under the act of 1878 and the commission of the peace they can, but now rarely do, exercise an original and summary jurisdiction as to articles of the peace (see Recognition). They exercise no original or general jurisdiction in the county before themselves or before courts of summary jurisdiction and returned to them for record or forfeiture, but by the Summary Jurisdiction Act 1879 the exercise of the latter power has been redefined.

**Appellate.**—An appeal lies to quarter sessions from convictions by a court of summary jurisdiction only where such an appeal is expressly given by statute. The number of statutes giving such right is small, and they are considerably increased by the Summary Jurisdiction Act 1879, which allows (s. 19) an appeal (with certain exceptions) from every conviction or order of a court of summary jurisdiction inflicting imprisonment, whereas the cases for appeal may be brought in accordance with the act giving the appeal in the Summary Jurisdiction Acts. Most of the special procedure in statutes giving the right to appeal has been swept away by the Summary Jurisdiction Act 1884.

**Civil Jurisdiction, Original.**—Originally the county justices were confined to the exercise in or out of sessions of the powers given by the commission of the peace and of certain statutory duties as to house &c. Under the Tudors and Stuarts the justices acting under the supersession act, was no longer referred to the "king's bench," gradually became the rulers of the county in administrative and social as well as judicial matters (F. W. Maitland, Justice and Police, 1886, p. 80). The process by which this result was attained is described in the Municipal Corporation Act 1888. The effect of the change was the supersession by nominees of the crown of the common law authorities and officers of county, hundred and township. But the change extended only to a small extent to municipal boroughs. By legislation in and since 1888 most of the administrative powers and duties of justices in general and quarter sessions have been transferred to the incorporated and elective councils of counties, boroughs and urban and rural districts. But the justices still possess certain original, civil or quasi-civil
Quarter-staff—Quartz

jurisdiction with respect to the extinction of licences to sell intoxicants, and jointly with the county councils over the county police, and to closing highways, and also powers to fix the petty sessional divisions of their county.

Appellate jurisdiction in quarter sessions have original jurisdiction in any matter as to which two justices have jurisdiction, unless the statute giving the jurisdiction gives an appeal to quarter sessions as a result of this rule. Most of the civil jurisdiction of quarter sessions is, therefore, civil in its character, i.e., dealing with civil actions out of quarter sessions as to the settlement and removal of paupers, or under the Highway, Licensing and Bastardy Acts, or as to appeals against assessments or rating. The procedure as to such cases depends upon the particular statute or Act. It is given and partly on the general provisions of the Summary Jurisdiction Acts 1879 and 1884. In substance their only original jurisdiction in civil or quasi-civil matters is now in cases of apprenticeship, and in cases of petty sessions where correction of fines, &c., is required by the Summary Jurisdiction Acts.

Appeal from Quarter Sessions. — There is no appeal properly so-called from quarter sessions to the High Court either on facts or law, but decisions on law may be reviewed by the High Court (king's bench division) by means of certiorari, mandamus or prohibition. Appeals on indictment proceedings out of quarter sessions are within the provisions of the Criminal Appeal Act 1907 (see Appeal), except convictions on indictments for obstruction or non-repair of a public bridge, highway or river, from which an appeal lies to the House of Lords under the Criminal Law and Procedure Act 1849. Questions of law alone can be referred by special case, and there is no means of compelling the court to state a case. The procedure as to cases not within the acts of 1848, 1849, and 1869 is governed by the Quarter Sessions Act, s. 2 of the Judicature Act 1874, which gives the High Court certain powers of drawing inferences of fact from the evidence taken in the court below.

Quarter-staff.—Ancient implements of war used as batons. The quarter-staff is a long-styled staff, it is generally 9 ft. in length, used as a means of attack and defence; originally no doubt it was the cudgel or sapling with which many heroes are described by early writers as being armed. The quarter-staff attained great popularity in England in the middle ages. It was usually made of oak, the ends often shod with iron, and it was held with both hands, the right hand grasping it one quarter of the distance from the lower end (whence the name) and the left at about the middle.

Egerton Castle (Schools and Masters of Fence) says that the staff was the "foll," or practice-substitute for the long sword, or two-hander. In earlier times it may also have been used as a practice weapon for the spear and bill. In the prints illustrative of the life of Richard Beauchamp, earl of Warwick (1382-1439), reproduced in Joseph Strutt's Manners, Customs, Arms, Habits, &c., of the Inhabitants of England, may be seen a combat between two knights after they have splintered their lances and dismounted, in which both are fighting with pointed staves as long as a quarter-staff and held in the same manner. In the 17th century the staff was still popular in England.

At the present time the quarter-staff is used to a limited extent in military circles as a school for bayonet play. It is somewhat lighter than the old weapon, being usually made of bamboo and about 8 ft. long. Sabre-masks, gloves, padded jackets and quarter-staff are worn, and the weapon is led by Captain A. Hutton (Cold Steel) the Great Stick, about 5 ft. long and made of stout rattan, is used in the French and Italian armies in general gymnastic exercises and as a school for bayonet play. The Italian method rather resembles that of the old two-handled sword, while the French approaches more closely to English quarter-staff play.

Quarto, a shortened form of Lat. in quarto, "in a fourth," i.e., of a sheet of paper, applied to a size of paper, and to a size of a printed volume. Paper is in quarto when a whole sheet is folded twice so as to form four leaves; a book is technically termed of "quarto" size when made up of sheets folded twice.

Quartz, a widely distributed mineral species consisting of silicic acid, or silica (SiO₂). It is the commonest of minerals, and is met with in the greatest variety of forms and with very diverse modes of occurrence. The various forms of silica have attracted attention from the earliest times, and the water-clear crystallized variety was known to the Greeks as κρεσιλλος (clear ice), being supposed by them to have been formed from water by the intense cold of the Alps; hence the name "crystal," or more commonly rock-crystal, applied to this variety. The name crystall is an old German word of uncertain origin: it was used by G. Agricola in 1529.
Quartz is a mineral which is put to many uses. Several of the varieties are cut into gems and ornaments, balance weights, pivot supports for delicate instruments, agate mortars, &c.; or used for engraving, for instance, cameos and the elaborately carved crystal vases of ancient and medieval times. Clear transparent rock-crystal is used for optical purposes and spectacle lenses. Fused quartz has recently been used for the construction of lenses and laboratory vessels, or it may be drawn out into the finest elastic fibres and used for suspending mirrors, &c., in physical apparatus. For striking fire, flint is used even to the present day. Buhrlstone, a cellular variety of chalcedonic quartz from the Tertiary strata of the Paris basin, is largely used for millstones. Quartz is a valuable grinding and polishing material, and is used for making sandpaper and scouring-soap. It is also largely used in the manufacture of glass and porcelain, "sliver sand" being a pure quartz sand.

Quartz crystallizes in the trapezohedral-hemihedral class of the rhombohedral division of the hexagonal system. Crystals of this class possess neither planes nor centre of symmetry, but only axes of symmetry: perpendicular to the principal triad axis there are three unterminal dyad axes of symmetry. Usually, however, this lower degree of symmetry is not indicated by the faces developed on the crystal. The faces of quartz are determined only by the faces of a hexagonal prism [211] and a hexagonal bipyramid (fig. 1), though sometimes the prism is absent (fig. 2). Frequently the faces are of different sizes (fig. 3): mis-shapen crystals are common and sometimes very puzzling, but they can always be orientated by the aid of the very characteristic striations on the prism faces, which serve also to distinguish quartz from other minerals of similar appearance. These striations (fig. 3) are horizontal in direction, being parallel to the edges of intersection between the prism and pyramid faces, and are due to the frequent oscillatory combination of these faces. The apparent hexagonal bipyramid is really a combination of two rhombohedra, the direct rhombohedron r [100] and the inverse rhombohedron s [211]. The faces of these two rhombohedra exhibit differences in surface characters, those of r being usually brighter in lustre than those of s; further, the former often predominate in size (figs. 4 and 5), and the latter may sometimes be completely absent. When both the prism and the rhombohedron s are absent, the crystals resemble cubes in appearance, since the angles between the faces of the rhombohedron are 85° 46'. The additional faces s and x (figs. 4 and 5), which indicate the true degree of symmetry of quartz, are of comparatively rare occurrence except on crystals from certain localities. The six small faces [412] situated on alternate corners at each end of the crystal, are called the "rhomb" faces, because of their shape; it extended they would give a trigonal bipyramid. The "trapezohedral," or "plagioclase," faces [211] belong to the trapezohedron. The two crystals shown in figs. 4 and 5 are of intersection with r; this serves to distinguish r and s, and thus, in the absence of x faces, to distinguish left- or right-handed crystals. Numerous other faces have been observed on crystals of quartz, but they are of rare occurrence. The basal planes, so common on many other hexagonal minerals, are also found in quartz, but the greatest rarity in quartz, and when present only appears as a small rough face formed by the corrosion of the crystal. Faces of prisms other than m are also small and of exceptional occurrence.

Twinned crystals of quartz are rare, but are complex in habit and can only be deciphered when the faces s and x are present, which is not often the case. Usually they are interpenetration twins with the principal axis as twin-axis; the prism planes of the two individuals coincide, and the other opposite faces fall into the plane of projection. Such twin planes therefore may be mistaken for simple crystals unless they are attentively studied; but the twinning is often made evident by the presence of irregularly bounded areas of the diller s faces coinciding with the brighter r faces. In a rarer type of twinning, in which the twin plane is 5 [211] (a plane transverse to the edge between r and s), the two individuals are united in juxtaposition with their principal axis nearly at right angles (84° 32'). A few magnificent specimens of rock-crystal twinned according to this type have been found at La Gardette in Isère, and in Japan they are somewhat abundant.

The pyro-electric characters of quartz are closely connected with its peculiar type of symmetry and especially with the three unterminal dyad axes. A crystal becomes positively or negatively electrified by the action of heat or cold, and by temperature changes. A similar distribution of electric charges is produced when a crystal is subjected to pressure; quartz being thus also piezo-electric. Etched figures, both natural and artificial (in the latter case produced by the action of hydrofluoric acid), often describe the face-pairs in accordance with the symmetry, and may serve to distinguish left- and right-handed crystals.

In its optical characters, quartz is also of interest, since it is one of the two minerals (calcite being the other) that are uniaxial polarizing. This phenomenon is connected with the symmetry of the crystals, and is also shown by the crystals of certain other substances in which there are neither planes nor centre of symmetry. A ray of plane-polarized light traversing a right-handed crystal of quartz in the direction of the triad axis has its plane of polarization rotated to the right, while a left-handed crystal rotates it to the left. A section 1 mm. thick, cut perpendicular to the principal axis of a quartz crystal, rotates the plane of yellow (D) light through 22°, and of blue (G) light through 43°. Such a section when examined in the polariscope shows an interference figure with a coloured centre, there being no black cross inside the innermost ring (this is not shown in very thin sections). Superimposed sections of right- and left-handed crystals, as they sometimes are present in sections of twinned crystals, exhibit Airy's spirals in the polariscope. The indices of refraction of quartz for yellow (D) light are ω = 1.5442 and ε = 1.5333; the optic sign is therefore positive.

The hardness of quartz is 7 on Mohs' scale, and it cannot be scratched with a knife; its specific gravity is 2.65. There is no distinct cleavage; though an imperfect cleavage may sometimes be developed parallel to the faces of the rhombohedron r by plunging a heated knife into them. A characteristic feature of the crystallized mineral is a peculiar rippled or "thumb-marked" fracture is sometimes to be seen, especially in amethyst (q.v.), and is due to repeated intergrowths of right- and left-handed material. The mineral is a very poor conductor, with the exception of hydrofluoric acid, and is only slightly dissolved by solutions of caustic alkalis. It is insusible before the gas blowpipe, but in the oxohydrogen flame fuses to a clear colourless glass, which has added quartz, as may sometimes be present in sections of twinned crystals, exhibit Airy's spirals in the polariscope. The indices of refraction of quartz for yellow (D) light are ω = 1.5442 and ε = 1.5333; the optic sign is therefore positive.

Many peculiarities of the growth of crystals are well illustrated by the mineral quartz. Thus in "ghost quartz," in which one crystal is seen inside another, the stages of growth are marked out by thin layers of enclosed material. Envelopes of other minerals (rutile, chlorite, haematite, goethite, actinolite, and asbestos and many others) are extremely frequent in crystals of quartz. Cavities, either round or with the same shape ("negative crystals") as the surrounding crystal, and of which the number is apparently limitless, are also present in vast numbers. Usually these cavities contain a liquid (water, a saline solution, carbon dioxide or petroleum) and a movable bubble of gas. The presence of these enclosed impurities impairs the transparency of quartz crystals. Crystals of quartz are sometimes attached at one end to their rocky matrix, but sometimes, especially when embedded in a soft matrix of clay, gypsum or salt, they may be bounded on all sides by crystal faces (fig. 1). In size they vary from minute whitish bits, from minute sparkling points encrusting rock surfaces and often so thickly clustered together as to produce a drusy effect, to large single crystals measuring a yard in length and diameter and weighing half a ton.
The characters as given above apply more particularly to crystals of quartz, but in the various massive and compact varieties the material may be quite different in general appearance. Thus in the microcrystalline chaledony (q.v.) the lustre is waxy, the fracture fibrous or conchoidal, the crystals form by-roads only, and the flint and chert are compact and have a splintery fracture: jasper (q.v.) is a compact variety intermixed with much iron oxide and clay and has a dull and even fracture. Further, these varieties may be divided into two classes, according to whether the compact quartz or chryzohylite, being embedded in these either as irregularly shaped masses or as porphyritic crystals. In pegmatite (granite granite) and granite, it often forms a regular intergrowth with felspar. It is sometimes porphyritic, and in granite forms compact porphyritic and chryzohylite schists, a quartz-schist being composed largely of quartz. By the weathering of silicates, silica passes into solution and quartz is deposited as a secondary product in the cavities of basic igneous rocks, and in fact in the crevices and along the joints of rocks of almost all kinds. Extensive veins of quartz are especially frequent in schistose rocks. Vein-quartz, often of economic importance as a matrix of gold, may, however, in some cases have been of igneous origin. In general chert is usually the abundant gangue mineral; the crystals are often arranged perpendicularly to the walls of the lode, giving rise to a "comby" structure. In limestones of various kinds it occurs as nodules and bands of chert and, in this case, its compactness and its durability resistant to weathering agencies, it forms the bulk of sands and sandstones; and when the sand grains are cemented together by a later deposit of secondary quartz a rock known as chert or quartzite (q.v.) is formed. In the chryzohylite of porous rocks, i.e. quartzite, when the silica is much finer and a petrifying material replacing organic remains it is often met with. As a deposit from hot springs, quartz is much less common thanopal. Crystals of quartz may be readily prepared artificially by a number of methods: e.g. by heating glass or gelatinous silica with water under pressure.

For particulars respecting the special characters, modes of occurrence and localities of the more important varieties of quartz, reference may be made to the following articles: Amethyst, Aventurine, Bloodstone, Cannel, Cannel, Cats-Eye, Chalcedony, Chrysoprase, Flint, Heliotrope, Jasper, Mocha- Stone, Onyx, Rock-Crystal, Sard, Sardonyx. For other forms of silica see Opal and Friedelite. (L. S.)

QUARTZITE, in petrology, a sandstone which when the deposit of crystalline quartz between its grains has been compacted into a solid rock. As distinguished from sandstone, the quartzite is free from pores and have a smooth fracture, since when struck with the hammer they break through the sand grains, while in sandstones the fractures pass through the cementing material and the rounded faces of the grains are exposed, giving the broken surface a rough or granular appearance. The conversion of sandstone into quartzite is sometimes the work of percolating water under ordinary conditions. In the Reading beds of England, which are for the most part loose sands, there are often many large blocks of quartzite which weather out and are exposed at the surface, being known as greys-wethers. The silification of these rocks must have taken place at no great depth and under ordinary pressures. Most quartzites, however, are found among ancient rocks, such as the Cambrian or Pre-Cambrian. Instances are the Lickley quartzite of Shropshire, the Holyhead or Anglesey, the Dundee quartze, the Derwent and the Bann- shire, the Anglesea and the Cherbourg quartzite. As these rocks lie in regions where there has been a considerable amount of metamorphism we may infer that (in addition to time and pressure) folding and rise of temperature favour the production of this type of rock.

A normal quartzite has in microscopic section its clastic structure well preserved; the rounded sand grains are seen with patches of new quartz in the interspaces, and the latter is often deposited in crystalline continuity, so that the quartzite may have been formed either by crushing and folding movements or by the action of heat and pressure. The quartzite consists in large part of a mosaic of small crystalline fragments of irregular shape with interlocking margins; these are called "shered quartze," and when they contain white mica in parallel crystals the flakes they become more fusible and pass into quartz-schists. Where sandstones are baked by intrusive
impregnated by quartz, chaledony, and opal, derived from the silica set free by decomposition (kaolinitization) of the original felspar. This re-deposited silica forms veins and patches of indefinite shape or may bodily replace a considerable area of the rock by metasomatic substitution, but more commonly it occurs as crystalline masses which frequently assume a brownish, greenish, or bluish tint and are often found in spherulitic growths which yield an excellent black cross in polarized light. The microcrystalline ground-masses are those which can be resolved into their component mineral parts by grinding, while the other forms of quartz are composed essentially of quartz and felspars, which are often in grains of quite irregular shape (microgranitic). In other cases these minerals are in graphic intergrowth, often forming radiate growths of spherulites consisting of flores of extreme tenuity; this type is known as granophyre. There is another group of quartz which contains small rounded or shapeless patches of quartz in which many rectangular felspars are embedded; this structure is called microplightic, and though often primary is sometimes developed from secondary changes which involve the deposition of new quartz in the ground-mass. As a whole those quartz-porphries, which have microcrystalline ground-masses are rocks of intrusive origin. Elvan is a name given locally to the quartz-porphries which occur as inclusions in granite, and have been called hornfels; they are indurate and have a central cavity, often with deposits of quartz crystals; they also frequently exhibit a succession of rounded cracks or dark lines occupied by secondary products. Rocks having these structures are termed felspar porphries, and are frequently found in Jersey, the Vosges, and Hungary. It has been proposed to call them pyromérites. Much discussion has taken place regarding the origin of these spherulites, but it is generally admitted that most of them are of primary origin. For example, they have suffered extensive changes through decomposition and silification.

Many of the older quartz-porphries which occur in Palaeozoic and Pre-Cambrian rocks have been affected by earth movements, and we now generally distinguish them by the name of orthogneisses. They have a central cavity, often with deposits of quartz crystals, and they also frequently exhibit a succession of rounded cracks or dark lines occupied by secondary products. QUATERNIONS

719

therefore confine ourselves, so far as his predecessors are concerned, to attempts at interpretation which had geometrical applications in view.

One geometrical interpretation of the negative sign of algebra was early seen to be mere reversal of direction along a line. Thus, when an image is formed by a plane mirror, the distance of any point in it from the mirror is simply the negative of that of the corresponding point of the object. Or if motion in one direction along a line be treated as positive, motion in the opposite direction along the same line is negative. In the case of time, measured from the Christian era, this distinction is at once given by the letters a.d. or B.C., prefixed to the date. And to find the position, in time, of one event relatively to another, we have only to subtract the date of the second (taking account of its sign) from that of the first. Thus1 to find the interval between the battles of Marathon (490 B.C.) and Waterloo (A.D. 1815) we have:

\[ +1815 - (-490) = 2305 \text{ years.} \]

And it is obvious that the same process applies in all cases in which we deal with quantities which may be regarded as of one directed dimension only, such as distances along a line, rotations about an axis, &c. But it is essential to notice that this is by no means necessarily true of operators. To turn a line through a certain angle in a given plane, a certain operator is required; but when we wish to turn it through an equal negative angle we must not, in general, employ the negative of the former operator. For the negative of the operator which turns a line through a given angle in a given plane will in all cases produce the negative of the original result, which is not the result of the reverse operator, unless the angle involved be an odd multiple of a right angle. This is, of course, on the usual assumption that the sign of a product is changed when that of any one of its factors is changed,—which merely means that × is commutative with all other quantities.

John Wallis seems to have been the first to push this idea further. In his Treatise of Algebra (1685) he distinctly proposes to construct the imaginary roots of a quadratic equation by going out of the line on which the roots, if real, would have been constructed.

In 1804 the Abbé Buée (Phil. Trans., 1806), apparently without any knowledge of Wallis's work, developed this idea so far as to make it useful in geometrical applications. He gave, in fact, the theory of what in Hamilton's system is called Composition of Vectors in one plane,—i.e. the combination, by + and −, of complanar directed lines. His constructions are based on the idea that the imaginaries i × j = −k represent a unit line and its reverse, perpendicular to the line on which the real units 1 are measured. In this sense the imaginary expression a + b i − j is constructed by measuring a length a along the fundamental line (for real quantities), and from its extremity a line of length b in some direction perpendicular to the fundamental line. But he did not attack the question of the representation of products or quotients of directed lines. The step he took is really nothing more than the kinematical principle of the composition of linear velocities, but expressed in terms of the algebraic imaginary.

In 1806 (the year of publication of Buée's paper) Jean Robert Argand published a pamphlet2 in which precisely the same ideas are developed, but to a considerably greater extent. For an interpretation, it is assumed that the product of two directed lines in one plane, when each is expressed as the sum of a real and an imaginary part. This product is interpreted as another directed line, forming the fourth term of a proportion, of which the first term is the real (positive) unit-line, and the other two are the factor-lines. Argand's work remained unnoticed until the question was again raised in Gergonne's Annales, 1813, by J. F. Français. This writer stated that he had found the germ of his remarks among the papers of his deceased brother, and that they had come from Legendre, who had himself received them from some one unnamed. This led to a letter from Argand, in which he stated his communications with Legendre, and gave a résumé of the contents of his pamphlet. In a further communication to the Annales, Argand pushed on the applications of his theory. He has given by means of it a simple proof of the existence of n roots, and no more, in every rational algebraic equation of the nth order with real coefficients. About 1828 John Warren (1796–1852) in England, and C. V. Mourey in France, independently of one another and of Argand, reinvented these modes of interpretation; and still later, in the writings of Cauchy, Gauss and others, the properties of the expression a + b i − j were developed into the immense and most important subject now called the theory of complex numbers (see NUMBER). From the more purely symbolical view it was developed by Peacock, De Morgan, &c., as double algebra.

Argand's method may be put, for reference, in the following form. The directed line whose length is a, and which makes an angle θ with the real (positive) unit line, is expressed by \( a(\cos \theta + i \sin \theta) \), and regarded as the sum of two such lines (formed by adding together the real and the imaginary parts of two such expressions) can, of course, be expressed as a third directed line,—the diagonal of the parallelogram of which they are conterminous sides. The product, of the two such lines is, as we have seen, given by

\[ a(\cos \theta + i \sin \theta) \cdot b(\cos \phi + i \sin \phi) = ab(\cos(\theta + \phi) + i \sin(\theta + \phi)) \],

Its length is, therefore, the product of the lengths of the factors, and its inclination to the real unit is the sum of those of the factors. If we write the expressions for the two lines in the form A+Bi, A′+B′i, the product is AA′−BB′+(AB′+BA′); and the fact that the length of the product line is the product of those of the factors is seen in the expression for its length, which may be written

\[ (A^2+B^2) = (A^2-A'B'+B^2-A'B)^2 + (A'B'−BA')^2 \].

In the modern theory of complex numbers this is expressed by saying that the Norm of a product is equal to the product of the Norms of the factors.

Argand's attempts to extend his method to space generally were fruitless. The reasons will be obvious later; but we mention them just now because they called forth from F. J. Servois (Gergonne's Annales, 1813) a very remarkable comment, in which was contained the only yet discovered trace of an anticipation of the method of Hamilton. Argand had led to deny that such an expression as \( i^2 \) could be expressed in the form A+Bi,—although, as is well known, Euler showed that one of its values is a real quantity, the exponential function of \( \pi i \). Servois says so. Instead of referring to the general representation of a directed line in space:

L'analogue semblerait exiger que le trinôme fût de la forme

\[ p \cos a + q \cos b + r \cos v \]

\[ \alpha, \beta, \gamma \text{ étant les angles d'une droite avec trois dures} \]

\[ \text{rectangulaires; ct qu'on ait} \]

\[ (p \cos a + q \cos b + r \cos v)(p' \cos a' + q' \cos b' + r' \cos v) = p q r + q r p + r p q \]

\[ = \cos(\theta + \phi + \psi) . \]

\[ \text{Les valeurs de} \ p, q, r, p', q', r', \text{qui} \]

\[ \text{satisferraient à cette condition seraient} \]

\[ \text{absurdes}; \text{mais seraient-elles} \]

\[ \text{réductibles à la forme} \]

\[ \text{Voulez-vous} \]

\[ \text{une question d'analyse fort singulière que je soumet à vos lumières} \]

\[ \text{La simple proposition que je vous en fais suffit pour vous faire} \]

\[ \text{que je ne crois point que toute fonction analytique non réelle soit} \]

\[ \text{vraiment réductible à la forme} \]

\[ A + B = 1. \]

As will be seen later, the fundamental i, j, k of quaternions, with their reciprocals, furnish a set of six quantities which satisfy the conditions imposed by Servois. And it is quite certain that they cannot be represented by ordinary imaginary.

Something far more closely analogous to quaternions than anything in Argand's work ought to have been suggested by De Moivre's theorem (1730). Instead of regarding, as Buée and Argand had done, the expression \( a(\cos \theta + i \sin \theta) \) as a directed line, let us suppose it to represent the operator which, when applied to any line in the plane in which \( \theta \) is measured, turns it in that plane through the angle \( \theta \), and at the same time increases its length in the ratio \( a : 1 \). From the new point of view we see at once, as it were, why it is true that

\[ (\cos \theta + i \sin \theta) = \cos 2\theta + i \sin 2\theta. \]
For this equation merely states that \( m \) turnings of a line through successive equal angles, in one plane, give the same result as a single turning through \( m \) times the common angle. To make this process applicable to any plane in space, it is clear that we must have a special value of \( i \) for each such plane.

In other words, a unit line, drawn in any direction whatever, must have \(-i\) for its square. In such a system there will be no line in space specially distinguished as the real unit line; all will be alike imaginary, or rather alike real. We may state, in passing, that every quaternion can be represented as \( a (\cos \theta + i \sin \theta) \), where \( a \) is a real number, \( \theta \) a real angle, and \( \pi \) a directed unit line whose square is \(-1\). Hamilton took this grand step, but, as we have already said, without any help from the previous work of De Moivre. The course of his investigations is minutely described in the preface to his first great work (Lectures on Quaternions, 1853) on the subject. Hamilton, like most of the many inquirers who endeavoured to give a real interpretation to the imagery of common algebra, found that at least two kinds, orders or ranks of quantities were necessary for the purpose. But, instead of dealing with points on a line, and then wandering out at right angles to it, as Bué and Argand had done, he chose to look on algebra as the science of "pure time," and to investigate the properties of "sets" of time-steps. In its essential nature a set is a linear function of any number of "distinct" units of the same species. Hence the simplest form of a set is a "couple"; and it was to the possible laws of combination of couples that Hamilton first directed his attention. It is obvious that the way in which the two separate time-steps are involved in the couple will determine these laws of combination. But Hamilton’s special object required that these laws should be such as to lead to certain assumed results; and he therefore commenced by assuming these, and from the assumption determined how the separate time-steps must be involved in the couple. It was necessary to form the product of "sets" of time-steps, and a parenthesis to denote a couple, the laws assumed by Hamilton as the basis of a system were as follows:

\[
\begin{align*}
(B_1, B_2) \cdot (A_1, A_2) &= (B_1 - A_1, B_2 - A_2) = (a, b) (\alpha, \beta) = (\alpha a + \beta b, \alpha b - \beta a). \\
(a, b) \cdot (\alpha, \beta) &= (a, b) (\alpha, \beta) = (a, b). \\
\end{align*}
\]

To show how we give, by such assumptions, a real interpretation to the ordinary algebraic imaginary, take the simple case \( a = 0, b = 1 \), and the second of the above formulas gives

\[
(0, 1)(\alpha, \beta) = (\alpha, 0).
\]

Multiply once more by the number-couple \((0, 1)\), and we have

\[
(0, 1)(0, 1)(\alpha, \beta) = (0, 1)(\beta, \alpha) = (a, 0) = (a, b)
\]

Thus the number-couple \((0, 1)\), when applied to a step-couple, simply changes its sign. That we have here a perfectly real and intelligible interpretation of the ordinary algebraic imaginary is easily seen by an illustration, even if it be a somewhat extravagant one. Some Eastern potentate, possessed of absolute power, covets the vast possessions of his vizier and of his barber. He determines to rob them both (an operation which may be very satisfactorily expressed by \(-1\)); but, being a wag, he chooses his own way of doing it. He degrades his vizier to the office of barber, taking all his goods in the process; and makes the barber his vizier. Next day he repeats the operation. Each of the victims has been restored to his former rank, but the operator \(-1\) has been applied to both.

Hamilton, still keeping prominently before him as his great object the invention of a method applicable to space of three dimensions, proceeded to study the properties of triplets of the form \(x+iy+jz\), by which he proposed to represent the directed line in space whose projections on the co-ordinate axes are \(x, y, z\). The composition of two such lines by the algebraic addition of their several projections agreed with the assumption of Bué and Argand for the case of coplanar lines. But, assuming the distributive principle, the product of two lines appeared to give the expression

\[
xx' - yy' - zz' + i(yy' + zz') + j(xx' + zz') + k(xy' + yz')
\]

For the square of \( j \), like that of \( i \), was assumed to be negative unity. But the interpretation of \( j \) presented a difficulty—indeed the main difficulty of the whole investigation—and it is specially interesting to see how Hamilton attacked it. He saw that he could get a hint from the simpler case, already thoroughly discussed, provided the two factor lines were in one plane through the real unit line. This requires merely

\[
y : z :: y' : z' \text{ or } yz' - y'z = 0;
\]

but then the product should be of the same form as the separate factors. Thus, in this special case, the term in \( j \) ought to vanish. But the numerical factor appears to be \( yz'-yz \), while it is the quantity \( yz'-yz \) which really vanishes. Hence Hamilton was at first inclined to think that \( j \) must be treated as nil. But he soon saw that "a less harsh supposition" would suit the simple case. For his speculations on sets had already familiarized him with the idea that multiplication might in certain cases not be commutative; so that, as the last term in the above product is made up of the two separate terms \( ijy' \) and \( jiy' \), the term would vanish of itself when the factor-lines are coplanar provided \( ij = -ji \); for it would then assume the form \( ij(y'z'-yz') \). He had now the following expression for the product of any two directed lines:

\[
xx' - yy' - zz' + i(yy' + zz') + j(xx' + zz') + k(xy' + yz')
\]

But his result had to be submitted to another test, the Law of the Norms. As soon as he found, by trial, that this law was satisfied, he took the final step. "This led me," he says, "to conceive that perhaps, instead of seeking to confine ourselves to triplets, . . . we ought to regard these as only imperfect forms of Quaternions . . . and that thus my old conception of sets might receive a new and useful application." In a very short time he settled his fundamental assumptions. He had now three distinct space-units, \(i, j, k\); and the following conditions regulated their combination by multiplication:

\[
i^2 = j^2 = k^2 = -1, \quad ij = -ji = k, \quad jk = -kj = i, \quad ki = -ik = j
\]

And now the product of two quaternions could be at once expressed as a third quaternion, thus:

\[
(a + ib + ic + kd)(a' + ib' + ic' + kd') = A + iB + jC + kD
\]

where

\[
A = aa' - bb' - cc' - dd', \quad B = ab' + ba' + cd' - dc', \quad C = ac' + ca' + bd' - db', \quad D = ad' + da' + bc' - cb'.
\]

Hamilton at once found that the Law of the Norms holds,—not being aware that Euler had long before decomposed the product of two sums of four squares into this very set of four squares. And now a directed line in space came to be represented as \(ix+iy+iz\), while the product of two lines is the quaternion

\[
-(xx'+yy'+zz') + i(yy'-zz') + j(xx'-zz') + k(xy'-yz').
\]

To any one acquainted, even to a slight extent, with the elements of Cartesian geometry of three dimensions, a glance at the extremely suggestive constructions of this expression shows how justly Hamilton was entitled to say: "When the conception . . . had been so far unfolded and fixed in my mind, I felt that the new instrument for applying calculation to geometry, for which I had so long sought, was now, at least in part, attained." The date of this memorable discovery is October 16, 1843.

Suppose, for simplicity, the factor-lines to be each of unit length. Then \(x, y, z, x', y', z'\) express their direction-coins. Also, if \(\theta\) be the angle between them, and \(x, y, z\) the direction-coins of a line perpendicular to each of them, we have \(xx' + yy' + zz' = \cos \theta\), \(yy' - zz' = x'z = x'z\sin \theta, \&c.,\) so that the product of two unit lines is now expressed as \(-\cos \theta + (ix'y' + jx'z' + kx'y') \sin \theta\). Thus, when the factors

\[
1 \text{ It will be easy to see that, instead of the last three of these, we may write the single one } ijk = -1.
\]
are parallel, or \( \theta = 0 \), the product, which is now the square of any (unit) line is \(-1\). And when the two factor lines are at right angles to one another, or \( \theta = \pi/2 \), the product is simply \( x^2 + y^2 + z^2 \), the unit line perpendicular to both. Hence, in this lies the main element of the symmetry and simplicity of the quaternion, for all systems of three mutually rectangular unit lines in space have the same properties as the fundamental system \( i, j, k \). In other words, if the system (considered as rigid) be made to turn about till the one with \( i \) and the second with \( j \), the product will coincide with \( k \). This fundamental system, therefore, becomes unnecessary; and the quaternion method, in every case, takes its reference lines solely from the problem to which it is applied. It has therefore, as it were, a unique internal character of its own.

Hamilton, having gone thus far, proceeded to evolve these results from a characteristic train of a priori or metaphysical reasoning. Let \( l, m, n \) be the product of the directed line \( \alpha \), it is something which has quantity; i.e. it may be halved, or doubled, for instance. Also let us assume \( \alpha \) space to have the same properties in all directions, and make the convention \( (b) \) that to change the sign of \( \alpha \) we must change the direction of the line of its symmetry. Let \( \alpha \) be the product of two directed lines which have the same direction cannot be, even in part, a directed quantity. For, if the directed part have the same direction as the factors, \( (b) \) shows that it will be reversed by reversing either, and therefore will recover its original direction when both are reversed. But this would obviously be inconsistent with \( (a) \). If it be perpendicular to the factor lines, \( (a) \) shows that it must have simultaneously every such direction. Hence it must be a pure number.

Again, the product of two lines at right angles to one another cannot, even in part, be a number. For the reversal of either factor must, by \( (b) \), change its sign. But, if we look at the two factors in the light of \( (a) \), the sign of \( \alpha \) must not change. But there is nothing to prevent its being represented by a directed line if, as further applications of \( (a) \) and \( (b) \) show we must do, we take it perpendicular to each of the factor lines. Hamilton seemed satisfied with the application of this property to the generality of a quaternion, depending as it does on a numerical and a directed part. He indulged in a great deal of speculation as to the existence of an extra-axial unit, which was to furnish the reason of the numerical part, and render the quaternion homogeneous as well as linear. But for this we must refer to his own works.

Hamilton was not the only worker at the theory of sets. The year after the first publication of the quaternion method, there appeared a work of great originality, by Grassmann,\(^1\) in which results closely analogous to some of those of Hamilton were given. In particular, two species of multiplication ("inner" and "outer") of directed lines in one plane were given. The results of these two kinds of multiplication correspond respectively to the numerical and the directed parts of Hamilton's quaternion product. But Grassmann distinctly states in his preface that he had not had leisure to extend his method to angles in space. Hamilton and Grassmann, while their earlier work had much in common, had very different objects in view. Hamilton had geometrical application as his main object; when he realized the quaternion system, he felt that his object was gained. For to him the constant ambition was to con his himself to the development of his method. Grassmann's object seems to have been, all along, of a much more ambitious character, viz. to discover, if possible, a system or systems in which every conceivable mode of dealing with sets should be included. That he made very great advances towards the attainment of this object all will allow; that his method, even as completed in 1865, fully attains it is not so certain. But his claims, however great they may be, can in no way conflict with those of Hamilton, whose mode of multiplying couples (in which the "inner" and "outer" multiplication are essentially involved) was produced in 1833, and whose quaternion system was completed and published before Grassmann had elaborated for press even the rudimentary portions of his own system, in which the veritable difficulty of the whole subject, the application to angles in space, had not even been attacked. Grassmann.\(^2\) in 1853-4 a savage onslaught on Cauchy (we), we seem the conception of a quaternion, but not in the way Hamilton, in the second edition of his work. But in 1857, in the "Auszgaben der Mathematische Annalen," xii., he gave a paper "On the Place of Quaternions in the "Auszgaben der Mathematische Annalen," xii., he gave a paper "On the Place of Quaternions in the Ausdehnungslehre," in which he condemns, as far as he can, the nomenclature and methods of Hamilton.

There are many other systems, based on various principles, which have been given for application to geometry of directed lines, but those which deal with products of lines are all of such complexity that they practically useless in application. Others, such as the Barycentrische Calcul of Möbius, and the Méthode des équipelements of Bellavitis, give elegant modes of treating space problems, so long as we confine ourselves to projective geometry and matters of that order; but they are limited in their field, and therefore need not be discussed here. More general systems, having close analogies to quaternions, have been given since Hamilton's discovery was published. As instances we may take Goodwin's and O'Brien's papers in the Cambridge Philosophical Transactions for 1849. (See also ALGEBRA: special kinds.)

Relations to other Branches of Science.—The above narrative shows how close is the connexion between quaternions and the ordinary Cartesian space-geometry. Were this all, the gain by their introduction would consist mainly in a clearer insight into the mechanism of co-ordinate systems, rectangular or not—a very important addition to theory, but little advance so far as practical application is concerned. But, as yet, we have not taken advantage of the perfect symmetry of the method. When that is done, the full value of Hamilton's grand step becomes evident, and the gain is quite as extensive from the practical as from the theoretical point of view. Hamilton, in fact, remarks, "I regard it as an inelegance and imprecation that in this calculus, or rather in the state to which it has hitherto been unfolded, whenever it becomes, or seems to become, necessary to have recourse ... to the resources of ordinary algebra, for the solution of equations in quaternions." This refers to the use of the \( x, y, z \) co-ordinates,—associated, of course, with \( i, j, k \). But when, instead of the highly artificial expression \( ix + jy + kz \), to denote a finite directed line, we employ a single letter, \( a \) (Hamilton uses the Greek alphabet for this purpose), and that we are permitted to deal with it exactly as we should have dealt with the more complex expression, the immense gain is at least in part obvious. Any quaternion may now be expressed in numerous simple forms. Thus we may regard it as the sum of a number and a line, \( a + a \), or as the product, \( b\), or the quotient, \( b^\prime \), of two directed lines, \( a \), \( b \), while, in many cases, we may represent it, so far as it is required, by a single letter such as \( a \).

Perhaps to the student there is no part of elementary mathematics so repulsive as is spherical trigonometry. Also, everything relating to change of systems of axes, as for instance in the kinematics of a rigid system, where we have constantly to consider one set of rotations with regard to axes fixed in space, and another set with regard to axes fixed in the system, is a matter of troublesome complexity by the usual methods. But every quaternion formula is a proposition in spherical (sometimes degrading to plane) trigonometry, and has the full advantage of the symmetry of the method. And one of Hamilton's earliest advances in the study of his system (an advance independently made, only a few months later, by Arthur Cayley) was the interpretation of the singular operator \( q^{-1} \), for which \( q \) is a quaternion. Applied to any directed line, this operator at once turns it, conically, through a definite angle, about a definite axis, and the rotation so produced can be exhibited by means of a model. Had quaternions effected nothing more than this, they would still have inaugurated one of the most necessary, and apparently impracticable, of reforms.

The physical properties of a homogeneous body (provided they vary continuously from point to point) are known to depend, in the neighbourhood of any one point of the body, on a quadric function of the co-ordinates with reference to that point. The

---

1 Die Ausdehnungslehre, Leipzig, 1844; 2nd ed., vollständig und in stark er Mehrfachung, Berlin, 1862. See also the collected works of Möbius, and those of Clifford, for a general explanation of Grassmann's method.
same is true of physical quantities such as potential, temperature, &c., throughout small regions in which their variations are continuous; and also, without restriction of dimensions, of moments of inertia, &c. Hence, in addition to its geometrical applications to surfaces of the second order, the theory of quadric functions of position is of fundamental importance in physics. Here the symmetry of position at once to the selection of the three principal axes as the directions for \( i, j, k \); and it would appear at first sight as if quaternions could not simplify, though they might improve in elegance, the solution of questions of this kind. But it is not so. Even in Hamilton's earlier work it was shown that all such questions were reducible to the solution of linear equations in quaternions; and he proved that, in turn, depended on the determination of a certain operator, which could be represented for purposes of calculation by a single symbol. The method is essentially the same as that developed, under the name of "matrices," by Cayley in 1858; but it has the peculiar advantage of the simplicity which is the natural consequence of entire freedom from conventional reference lines.

Supplementary Considerations.—There are three fairly well-marked stages of development in quaternions as a geometrical method: (1) Generation of the concept through imaginaries and development into a method applicable to Euclidean geometry. This was the work of Hamilton himself, and the above account (contributed to the 9th ed. of the Encyc. Brit. by Professor G. P. Tait, who was Hamilton's pupil and after him the leading exponent of the subject) is a brief résumé of this first, and by far the most important and most difficult, of the three stages. (2) Physical applications. Tait himself may be regarded as the chief contributor to this stage. (3) Geometrical applications, different in kind from, though more or less allied to, those in connexion with which the method was originated. These last include (a) C. J. Joly's projective geometrical applications starting from the interpretation of the quaternion as a point-symbol; (b) these applications may be said to require no addition to the quaternion algebra; (c) W. K. Clifford's bi-quaternions and G. Combiac's tri-quaternions, which require the addition of quasi-scalars, independent of one another and of true scalars, and analogous to true vectors. As an algebraic method quaternions have from the beginning received much attention from mathematicians. An attempt has recently been made under the name of multelions to systematize this algebra.

We select for description stage (3) above, as the most characteristic development of quaternions in recent years. For (3) (c) we are constrained to refer the reader to Joly's own Manual of Quaternions (1905).

The impulse of W. K. Clifford in his paper of 1873 ("Preliminary Sketch of Bi-Quaternions," Mathematical Papers, p. 181) seems to have come from Sir R. S. Ball's paper on the Theory of Screws, published in 1872. Clifford makes use of a quasi-scalar \( \omega \), commutative with quaternions, and such that if \( p, q, \&c. \), are quaternions, when \( p + q = p' + q' \), then necessarily \( \omega = \omega' \). He considers two cases, viz. \( \omega = \omega \) suitable for non-Euclidean space, and \( \omega = \omega \) suitable for Euclidean space; we confine ourselves to the second, and will call the indicated bi-quaternion \( p + q \) an octonion. In octonions the analogue of Hamilton's vector is localized to the extent of being confined to an indefinitely long axis parallel to itself, and is called a rotor; if \( p \) is a rotor then \( p + q \) is parallel and equal to \( p \), and, like Hamilton's vector, \( \omega \) is not localized; \( \omega \) is therefore called a vector, though it is the case of such vectors \( \omega \) alone that is zero because \( \omega^2 = 0 \). The equation \( p + q = \omega \) is therefore of the form \( \omega + \omega \), \( \omega \) is therefore called a vector, though it is the case of such vectors \( \omega \) alone that is zero because \( \omega^2 = 0 \). This is the basis of a method parallel throughout to the quaternion method; in the specification of rotors and motors it is independent of the origin which for these purposes the quaternion method, pure and simple, requires.

Combiac is not content with getting rid of the origin in these limited circumstances. The fundamental geometrical conceptions are the point, line and plane. Lines and planes are independent of any method of motors, but points and planes cannot be so treated. He glances at Grassmann's method, but is repelled because he is seeking a unifying principle, and he finds that Grassmann offers him not one but many principles. He arrives at the tri-quaternion as the suitable fundamental concept.

We believe that this tri-quaternion solution of the very interesting problem proposed by Combiac is the best one. But the first thing that strikes one is that it seems unduly complicated. A point and a plane fix a line or axis, viz. that of the perpendicular from point to plane, and therefore a calculus of points and planes is ipso facto a calculus of lines also. To fix a weighted point and a weighted plane in Euclidean space we require 8 scalars, and not the 2 scalars of a tri-quaternion. We should expect some species of bi-quaternion to suffice. And this is the case. Let \( \eta \) be two quasi-scalars such that \( \eta^2 = \eta, \eta = \eta, \eta = \omega \). Then the bi-quaternion \( \eta + \omega \) is sufficient. The plane of \( \eta + \omega \) is \( \eta+\omega \), its equation is \( \frac{1}{2} \theta \), and its expression is the bi-quaternion \( \eta V + \omega \). Its position vector is \( \beta \), where \( \omega \beta = \beta (\text{or what is the same,} = [Vr + q, Vr, \omega]) \), and its expression is \( \eta \beta + \omega V \). (Note that the \( \frac{1}{2} \) here occurring is only required to ensure harmony with tri-quaternions of which our present bi-quaternions, as also octonions, are particular cases.) The point whose position vector is \( \eta V + \theta \) is on the axis and may be called the centre of the bi-quaternion; it is the centre of a sphere of radius \( \sqrt{\eta} \) with reference to which the point and plane are in the proper quaternion sense polar reciprocals, that is, the position vector of the point relative to the centre is \( \sqrt{\eta} \). QV and that of the foot of perpendicular from centre on plane is \( \sqrt{\eta} \). QV, the product being the (radius), that is, \( \sqrt{\eta} \). The axis of the member \( \theta x' Q' \) of the second complex \( Q, \theta' \) (where \( Q x = \theta Q' = \theta') \) and \( x, x' \) are scalars) is parallel to a fixed plane and intersects a fixed transversal, viz. the line parallel to \( q' q \) which intersects the axes of \( Q \) and \( Q' \); the plane of the member contains a fixed line; the centre is on a fixed ellipse which
intersects the transversal; the axis is on a fixed ruled surface to which the plane of the ellipse is a tangent plane, the ellipse being the section of the ruled surface by the plane; the ruled surface is a cylinder formed by a simple shear parallel to the transversal. In the third-order complex the center locus becomes a finite closed quartic surface, with three (one always real) intersecting nodal axes, every plane section of which is a trinodal quartic. The chief defect of the geometrical properties of these bi-quaternions is that the ordinary algebraic calculus finds no place among them, and in consequence $Q$ is meaningless.

Putting $z = \eta = \xi$ we get Combesiac's tri-quaternion under the form $Q = px + qy + oz + o + r$. This has a reciprocal $Q^{-1} = \frac{p}{p} - \frac{q}{q} - \frac{r}{r}$, and a conjugate $Q_{K} = (KQ)^{-1} = KQ$. The product $QQ$ of $Q$ and $Q$ is $px + qy + oz + o + r$. The semi-vector $\frac{1}{2}Q(1 - KQ)$ is a Combesiac's linear element and may be regarded as a point on a line; the quasi-quaternion (in a different sense from the rest of this article) $\frac{1}{2}(KQ)$ is Combesiac's scalar $(S + S)$. Combesiac's plane. Combesiac does not use $K$ and $Q_{K}$, and the product of two quaternions is $Q\cdot Q_{K}$.

The product of two octonions is $Q\cdot Q_{K}$. Combesiac's tri-quaternion may be regarded from several simplifying points of view. Thus, in his general tri-quaternion we might deal with products of an odd number of point-plane-scalars (of form $q + o$) which are themselves point-plane-scalars; and products of an even number which are octonions; the quotient of two point-plane-scalars would be an octonion, of two octonions an octonion, of an octonion by a point-plane-scalar or the inverse a point-plane-scalar. Again a unit point $\mu$ may be regarded as a multiplication changing (a) from octonion to point-plane-scalar, (b) from point-plane-scalar to octonion, (c) from point-plane-scalar to plane element, (d) from plane element to plane-scalar.

If $Q = px + qy + oz + o + r$ and we put $Q = (1 + t\omega)Q(1 + t\omega)^{-1}$ we find that the quaternion $t$ must be $2/(r - q - p)$, where $f(r) = -Q$. The point $P = VI$ may be called the centre of $Q$ and the length $Sf$ may be called the radius. If $Q$ and $Q_{K}$ are commutative, that is, if $QQ_{K} = QQ_{K}$, the point $Q = Q_{K}$ have the same centre and the same radius. This is a tri-quaternion, and $Q_{K}$ have a common centre and 3 equal and opposite radii; that is, the 3 of $KQ$ is the negative conjugate of that of $Q$. When $S_{K} = 0$, $(1 + t\omega)$ is an operator which shifts (without further change) the tri-quaternion operand an amount given by $\mu$ in direction and distance.

Bibliography.—In 1904 Alexander Macfarlane published a Bibliography of Quaternions and allied systems of Mathematics for the International Association for promoting the study of Quaternions and allied systems of Mathematics, published by the University Press; the pamphlet contains 86 pages. In 1901 and 1905 Sir W. R. Hamilton's classical Elements of Quaternions of 1860 was republished under C. J. Joly's editorship, in two volumes (London). Joly adds valuable notes and thirteen important appendices. In 1890 the 3rd edition of G. F. T. Sylvester's Elements of Quaternions appeared in Cambridge. In 1905 C. J. Joly published his Manual of Quaternions (London); the valuable contents of this are doubled by copious so-called examples; every earnest student should take the trouble of going through them. Joly's paper on quaternions and tri-quaternions (Paris, 1904); Don Francisco Pérez de Múoz, Introducción al estudio del cálculo de Cuaterniones y otras Álgebras especiales (Madrid, 1905); A. McCauley, Algebra after Hamilton, or Malveniens (Edinburgh, 1908). (A. MCA.)

Quatorzain is the term used in English literature, as opposed to “sonnet,” for a poem in fourteen rhymed iambic lines closing (as a sonnet strictly never does) with a couplet. The distinction was long neglected, because the English poets of the 16th century had failed to apprehend the true form of the sonnet, and called Petrar&amp;#39; s and other Italian poets' sonnets quatorzains, and their own incorrect quatorzains sonnets. Almost all the so-called sonnets of the Elizabethan cycles, including those of Shakespeare, Sidney, Spenser and Daniel, are really quatorzains. They consist of three quatrains of alternate rhyme, not repeated in the successive quatrains, and the whole closes with a couplet. A more perfect example of the form could hardly be found than the following, published by Michael Drayton in 1602:-

Dear why should you commend me to my rest,
When now the night doth summon all to sleep?

Methinks this time becometh lovers best,
Night was ordained together friends to keep.

How happy after are those sweet times spent
Which though the day conjoin by several flight,

The quiet evening yet together brings,
And each returns unto his love at night,

O thou that art so courteous unto me,
Why shouldst thou, Night, abuse me only thus,

That every creature to his kind dost call,

And yetst thou dost only sever us?

What should we do in such engineer's work,
If, when night comes, you bid me go away.

Donne, and afterwards Milton, fought against the facility and incorrectness of this form of metre and adopted the Italian form of sonnet. During the 19th century, most poets of distinction prided themselves on following the strict Petrarchan model of the sonnet, and particularly in avoiding the final couplet. In his most mature period, however, Keats returned to the quatorzain, perhaps in emulation with Shakespeare; and some of his examples, such as "When I have fears," "Standing aloof in giant ignorance," and "Bright Star," are the most beautiful in modern literature. The "Fancy in Nubibus," written by S. T. Coleridge in 1819, also deserves notice as a quatorzain of peculiar beauty. Quatrains, sometimes spelt Quatrain (from Fr. quatre, four), a piece of verse consisting of four rhymed lines. The length or measure of the verse is immaterial, but they must be bound together by a rhyme-arrangement. This form has always been popular for use in the composition of epigrams, on account of its brevity and neatness, and may be considered as a modification of the Greek or Latin epigram at its concisest.

Quatrefages de Béauro, Jean Louis Armand de (1810-1892), French naturalist, was born at Berthezine, near Vallerangue (Gard), on the 10th of February 1810, the son of a Protestant farmer. He studied medicine at Strassburg, where he took the double degree of M.D. and D.Sc., one of his theses being a Théorie d'un coup de canon (November 1891); next year he published a book, Sur les aérolithes, and in 1852 a treatise on L'Extraction de la vesse. Removing to Toulouse, he practised medicine for a short time, and contributed various memoirs to the Local Journal de médecine and to the Annales des sciences naturelles (1834-56). But being unable to continue his researches in the provinces, he resigned the chair of zoology to him, he held lower organisms, to the anthropods and man. Of his numerous essays in scientific periodicals, the more important were: Considérations sur les caq&rsquo;il&rsquo;ures zoologiques des rongeurs (1849); "De l'organisation des animaux sans vertébrés des Côtés de la Manche" (Ann. Sci. Nat., 1844); "Recherches sur
le système nerveux, l'embryogénie, les organes des sens, et la circulation des amniés" (Ibid., 1844-50); "Sur les affinités et les analogies des lombrics et des sangues" (Ibid.); "Sur l'histoire naturelle des tarets" (Ibid., 1848-49). Then there is the series Les Lézards (1848), a comprehensive study of this types inférieurs de l'embranchement des amnés," and the results of several scientific expeditions to the Atlantic and Mediterranean coastlands, Italy and Sicily, forming a series of articles in the Résultats des expéditions (1852-53); "Sur les Mollusques fossiles" (Ibid., 2 vols., 1854). These were followed in quick succession by the Physiologie comparée, metamorphoses de l'homme et des animaux (1851); Les Polynésiens et leurs migrations (1866); Histoire naturelle des amnés marins et de l'eau douce (2 vols., 1866); La Ronde et ses environs (1866); Robert sur l'histoire de l'Égyptologie (1867); Ch. Darwin et ses précurseurs français (1870), a study of evolution in which the writer takes somewhat the same attitude as A. R. Wallace, the Darwinian doctrine in its applied to man; La Race prehistorique (1871); Crania Ethnica, jointly with Dr Hamy (2 vols., with 100 plates, 1875-82), a classical work based on French and foreign anthropological data, analogous to the Crania Britannica of Thurman and Davis, and to S. G. Morton's Crania Americana and Crania Aegyptica (1877); Nouvelles Études sur la distribution géographique des négros (1882); Histoire et ses jeux savants (1884); and Histoire générale des races humaines (2 vols., 1886-89), the first volume being introductory, while the second attempts a complete classification.

QUATREFOIL, in Gothic architecture, the piercing of tracery in a window or balustrade with small semicircular openings known as "foils," the intersection of these foils is termed the cusp.

QUATREMÈRE, ÉTIENNE MARC (1782-1857), French Orientalist, the son of a Persian merchant, was born in Paris on the 12th of July 1782. Employed in 1807 in the manuscript department of the imperial library, he passed to the chair of Greek in Rouen in 1809, entered the Academy of Inscriptions in 1815, taught Hebrew and Aramaic in the Collège de France from 1819, and finally in 1827 became professor of Persian in the School of Living Oriental Languages.

Quatremère's first work was Recherches ... sur la langue et la littérature de l'Égypte (1808), showing that the language of ancient Egypt must be sought in Coptic. His translation of Makrize's Arabic history of the Mameluke sultans (2 vols., 1837-41) shows his erudition at the best. He published among other works Mémoires sur les Nabatéens (1835); a translation of Rashid al-Din's Histoires des Mongols de la Perse (1846); Mém. gèog. et hist. sur l'Égypte (1840); the text of Ibn Khaldun's Prolegomena; and a vast number of useful memoirs in the Journal asiatique. His numerous reviews in the Journal des savants should also be mentioned. Quatremère also published, in 1859, a dictionary of Egyptian and Arabian languages, fragments of which appear in the notes to his various works. His MS. material for Syriac has been utilized in Payne Smith's Thesaurus; of the slips he collected for a projected Arabic, Persian and Turkish lexicon some account is given in the preface to Doux Supp. aux dieu arabes. They are now in the Munich library. A biographical notice by M. Barthélemy Saint-Hilaire is prefixed to Quatremère's Mélanges d'histoire et de philologie orientale (1861).

QUAY, MATTHEW STANLEY (1832-1904), American political "boss," was born in Dillsburg, York county, Pennsylvania, on the 30th of September 1833. He graduated at Jefferson College (now Washington and Jefferson College) in 1850 and was admitted to the bar in 1854. He served in various capacities in the Civil War, and in 1865-1867 was a member of the state House of Representatives, becoming secretary of the commonwealth in 1873-1878 and again in 1879-1885, recorder of Philadelphia in 1878-1879, and state treasurer in 1881-1885. He was a leader of the Republican national executive campaign committee in 1884-1886 and a member of the United States Senate in 1887-1899 and again in 1903-1904. For nearly twenty years he dominated the government of Pennsylvania, and also played a very prominent part in national affairs. In 1899 he was brought to trial on a charge of misappropriating state funds, and, although he was acquitted, the feeling among the reform element in his own party was so bitter against him that the legislature was deadlocked and his re-election was postponed for two years. He died on the 28th of May 1904.

QUAY, a wharf or landing-place for the loading and unloading of water-borne cargo. The word, now pronounced like "key," takes the form of Fr. quai, older cay or caye, cf. Spanish cayo, a bar, barrier or reef. The earlier form in English is "key," as that, now partially settled, which is occupied by a wharf. Quay was also earlier pronounced "kye," and the change in pronunciation in the one word was followed also in the other. In spelling also the word was assimilated to "key," in the sense of a reef; or, especially, of the low range of reefs or islets on the coasts of Spanish America, e.g., on the coast of Florida, the chain of islets known as Florida Keys.

QUEBEC, a province of the Dominion of Canada, bounded S. by New Brunswick and the United States, W. by Ontario, N. by the district of Ungava, and E. by the gulf of St Lawrence and the strip of eastern Labrador which belongs to Newfoundland. If Ungava be considered as added to the province of Quebec, Hudson Strait is the northern boundary. The province includes the island of Anticosti, the Bird Islands and the Magdalen Islands, in the gulf of St Lawrence. The western boundary, separating Quebec from Ontario, extends through Point au Baril on the river St Lawrence to Point Fortune on the Ottawa river, from which place the boundary follows the Ottawa to Lake Temiscaming. From the north end of this latter lake it runs due north to Hudson Bay. The province of Quebec thus extends from Blanc Sablon, a fishing harbour at the mouth of the Bay of Fundy, to the Gulf of St Lawrence and the island of Anticosti (which separates Canada from Newfoundland) in 50° 7' W., to lake Temiscaming in 79° 40' W., a distance of about 1350 miles. The area of the province is 335,873 sq. m. The general direction of the province is north-east and south-west, following the course of its chief physical feature, the river St Lawrence. Speaking generally, it may be said that the province of Quebec comprises the hydrographical basin of the river St Lawrence as far west as the intersection of the parallel of 45° N. with the latter. The St Lawrence flows south the southern edge of its basin, only some 50,000 sq. m. of the area of the province lying south of the river.

The province of Quebec falls into three main physiographical divisions, viz.: (1) the Laurentian Highlands, (2) the Valley of the St Lawrence, and (3) the Notre Dame Mountains and the rolling country lying to the south-east of this range.

(1) The Laurentian Highlands are sometimes referred to as the "Laurentian Mountains," as they appear to constitute a mountain range when viewed from the gulf or the river St Lawrence. This portion of the province, however, is really a plateau having an elevation of 1000 to 2000 ft. above sea level, but this plateau is broken by deep valleys and basins, and the river St Lawrence is cut through a gap in the plateau. The plateau extends from the maritime provinces to Lake Superior, and is continued to Hudson Strait. Along the extreme eastern border of these Laurentian Highlands on the coast of Labrador, however, the country rises to much greater altitudes, forming an extremely rugged district which attains in places an elevation of 6000 ft. above sea-level. This plateau is characterized by a penepalein and is hump-backed in character, the surface, however, being but slightly accentuated and the sky line seen from the higher points in the area being nearly level. It is densely wooded and the rivers and streams issued from it are abundant and swift. Some of the rivers of the plateau are navigable and are subject to glacial action by the irregularly distributed drift which more or less covers the surface of the underlying rocks. From these lakes issue the Laurentian streams. These lakes and rivers form a continuous series of waterways that a traveller who knows their courses, and the portages connecting them, can traverse this immense tract of country in any direction he may choose.

These waterways are, moreover, clear and pure, and the country is one in which malaria and similar diseases are unknown. Some of the rivers draining the Laurentian country run in very deep, well-valled valleys or fjords cut in the solid rock; a number of which, comparable in character although perhaps not in depth to those of the Scandinavian countries, penetrate the St Lawrence peninsula north, east and south. As an example of such fjords in the province of Quebec, those occupied by the waters of the Hamiton, Mingan and Saguenay rivers may be cited as well as the Saguenay estuary itself. On the Pacific side, Temiscaming and the Mattawa river. The walls of solid gneiss between which the Sagueneay flows are in places from 1500 to 1800 ft. in height, while the waters of the river in places reach a depth of 140 ft. This Laurentian country in the province of Quebec and its continuation into the adjacent province contain the chief timber
supplies of the Dominion, supplies which with a little husbanding on the part of the government could be made to afford a bountiful supply of timber for all future generations. The country also contains valuable mineral deposits, and is the great home of the fur-land. As part of the Dominion southern border it supports a considerable agricultural population, the Laurentian country cannot be considered as one which in respect to its agricultural capabilities can ever take rank with the Great Lakes Country, and with the great plains and British Columbia which lie to the west.

(2) That portion of the lowlands of the St Lawrence valley which belongs to the province of Quebec forms a wedge-shaped area extending along the river from a short distance below the mouth of Quebec to the western border of the province. It is throughout a practically level plain of very fertile land, on which are situated the chief towns and cities of the province, and on it also are settled the chief of the population of the province. Lowlands extend on the north by the Laurentian plateau, and on the south by the Notre Dame Mountains, which physical features gradually converge, the latter mountains reaching the shore of the river St Lawrence a short distance to the east of the city of Quebec. The plain in this way gradually narrows on going to the north-east, and is finally closed off in that direction. It was a portion of this plain that was first occupied by the early French settlers. Much of its surface, as has been said, is absolutely level, and it nowhere exceeds an elevation of a few hundred feet. Its uniform expanse, however, is broken by a line of eight isolated hills composed of rocks of igneous origin, being a series of eroded remnants of ancient volcanoes which, according to the arrangements established by the striking features of the landscape. They are known as the Montebello hills and rise to elevations of 500 ft. to 1600 ft. above sea-level. From the summit of Mount Royal, at the foot of which lies the city, the entire contours of the province are visible, and the margin of the Laurentian Highlands may be seen bounding the horizon some 30 m. to the north, while southward the Green Mountains, and the Adirondacks in the state of New York, are distinctly visible.

(3) The Notre Dame Mountains and the Eastern Townshirds. The Appalachian Mountain range, passing out of the state of Vermont, where it is known as the Green Mountains, crosses into the province of Quebec, becoming the Chic-Choc Mountains and Memphremagog, and becoming lower and less rugged continues in a north-easterly direction to a point about 30 m. south of the city of Quebec. Thence it pursues its course, following the general trend of the St Lawrence, and the remaining portions of the range, which, as the shelf-land, is the continuation of the Laurentian Highlands, and gradually lowers from its southern margin, and reaches the latter river near Metis. From the border to this point the range is known as the Notre Dame Mountains. The highest peak in the Notre Dame Mountains is Sutton Mountain—3100 ft. Continuing on to the north-east it develops into the high land of the Gaspe Peninsula, of which the most elevated portion constitutes the Shickshock Mountains, the higher summits of which rise to elevations of 3000 to 4000 ft. above sea-level. The whole central area of the Gaspe Peninsula is covered with a dense forest of fir and pine.

To the south-east of the Notre Dame Mountains is an undulating country known as the “Eastern Townshirds.” These hills, as mentioned, are composed of rocks of igneous origin and more, and less rugged than the Notre Dame Mountains, the general elevation of the country being from 500 to 1000 ft. above sea-level. There are a number of large and fine lakes in this district, among which may be mentioned lakes Metapedia, Memphremagog, Aylmer, St Francis and Megantic.

In the belt of the Notre Dame Mountains the country is not in the strict sense of the term a mountainous one, but rather a rolling country containing much good farming and pastoral land, while the Eastern Townshirds is a fine agricultural country, bracing some of the best farming and grazing land in the Dominion. This latter district was originally settled by Loyalists from the United States at the time of the revolt of the colonies, but is now being occupied by people of English origin. The northern portions of the province, the younger generation of English-speaking Canadians preferring to take up land and settle in Ontario or the western provinces of Manitoba, Saskatchewan, Alberta and British Columbia.

The whole country is exceptionally well watered and abounds in fresh water lakes, large rivers, bays, estuaries. The principal rivers are the St Lawrence, which flows through the entire length of the province. A short distance above Montreal it receives from the north-west the Ottawa, a large and beautiful river over 600 m. in length with many tributaries, among which the most important are the Gatineau, the Lièvre, the North, the Rouge and the Kinojevis. The St Lawrence is navigable for large ocean steamships as far as Montreal, beyond which place navigation is interrupted by rapids. The St Maurice rises in Lake Oskelano, flowing into the St Lawrence at Three Rivers, and is over 400 m. long. It has many tributaries, and drains an area of 21,000 sq. m. Twenty-four miles above Three Rivers on the St Maurice are the falls of Shawinigan, 125 ft. high, from which a large amount of electrical power is obtained, a portion of which is used in the production of aluminium, while several thousand horse-power are transmitted to the city of Montreal. The Batsiscan river enters the St Lawrence at Batiscan. The Jacques Cartier, the Ste Anne and the Montmorency are northern tributaries of the St Lawrence. The Montmorency is famous for its falls, situated about 8 m. from Quebec city, and 250 ft. high. These beautiful falls, however, have in recent years been greatly reduced in volume, being largely employed for the development of electricity, and also for the supply of power to a large cotton-mill in the vicinity. Near these falls is Haldimand House, once the residence of the duke of Kent, father of Queen Victoria. The Saguennay rises in Lake St John and discharges into the St Lawrence at Tadoussac after a course of 100 m. On the south side of the St Lawrence is the Richelieu river, which rises in Lake Champlain and enters the St Lawrence at Sorel on Lake St Peter. Champlain sailed this river in 1609. Other important streams are the St Francis, rising in Lake Memphremagog; the Chaudiére, rising in Lake Memont, with its beautiful falls 125 ft. high about 10 m. above Quebec; the Chateauguay, Yamaska, Etchemin, du Loup, Assumption and Bécancour. Among the largest lakes in the province are Lake St John, which has an area of 360 sq. m.; Lake Temiscaming, having an area of 126 sq. m.; Lake Matapedia, Lake Megantic and Lake Memphremagog.

The largest islands in the province of Quebec are: Anticosti, now used as a game preserve; Bonaventure, an important fishing station to the east of Gaspe; and the Magdalen Islands, situated in the gulf of St Lawrence about 50 m. north of Prince Edward Island.

Geology and Minerals.—Beginning with the oldest rocks, the more northerly eastern part of the province of Quebec is underlain by the Laurentian series. This series is a great series of very highly altered sediments, largely limestones, known as the Grenville series, which is penetrated by great intrusions of anorthosite, &c., and is invaded by and rests upon enormous batholiths of granite, which are sometimes referred to as the "Fundamental Gneiss." The Grenville series is best developed along the southern margin of the Laurentian Highlands between Three Rivers and the Georgian Bay. Two of the great anorthosite intrusions are on the Sorel River, near the border to the north of Montreal and about Lake St John. The Laurentian system is succeeded to the south by the Potsdam sandstone, probably equivalent to the Upper Cambrian of Britain. On this rests a dolomite and limestone formation known as the "Fossiliferous Series," which, being rich in fossils, is the most largely developed in the province. Above this succession is the "Oolitic Series," or the "Oldest Shale," rich in graptolites and trilobites. This is succeeded by the Hudson River group composed largely of sandstones and calcareous beds. These constitute the complete Ordovician succession. Upper Devonian and Silurian beds, the latter holding fossil plants and fishes, occur in the south-east portion of the province, while on the shore of Chaleur Bay these are succeeded by the lowest beds of the Carboniferous. No coal occurs in the province of Quebec.

The Geological Survey of Canada, and the Dominion Townshirds there are great intercalations of ancient volcanic rocks and many important mineral deposits. Among these may be mentioned gold, copper, asbestos and chrome iron ore; also serpentine, iron, lead, zinc, and talc. Asbestos is by far the most extensive and most productive in the world, the chief centre of asbestos mining being at Thetford Mines. A large part of the country, more especially on the lower levels, is covered with Pleistocene deposits of the so-called Glacial till. Boulder clay is usually at the base of these deposits. On this rests a finer stratified blue clay, in some places rich in fossil shells and known as the Leda clay. It affords a good material for the manufacture of bricks. The upper beds of clays and gravels is known as the Saxicava sand. This is also stratified and frequently contains an abundance of fossils. These clayed clays and sands are due to a re-sorting of the boulder clay by the action of water, and the silts and gravels of the great river system with some subsequent elevation. In certain alluvial deposits in the vicinity of the St Maurice river there occur deposits of bog iron ore which have been worked for many years.

Quebec is ice free. In the winter the cold is generally steady and the atmosphere clear and bracing. About Montreal snow lies on the ground from the end of November
until the following April, affording good sleighing for four months in the door. The inhabitants enjoy with zest and spirit all the outdoor sports common in the country, such as skating, curling, tobog- ganning, snowshoeing, skiing and sledding. The snowfall is heavy, and though the winds are often sharp they are not often raw or damp, nor is there any fog. The summer is warm and pleasant. The extreme heat is indicated at 90° F. The finest season of the year is the autumn, which lasts about six or eight weeks. The following is a table of temperatures recorded by the meteorological stations at certain points in the province—

**Table showing Normal Temperature, Precipitation &c., at various Stations in the Province of Quebec.**

The normal percentage of bright sunshine at Montreal is 41 and at Quebec 39, a higher average than northern Europe. (F. D. A.)

**Area and Population.**—The boundaries of Quebec have been more than once enlarged since 1867. By the extension given to them in 1898, the province has an area of 3,511,873 sq. m., of which 341,756 sq. m. are land and 1,117 sq. m. are water. This estimate includes the islands of Orleans, Anticosti, and the Magdalen group, but not the gulf of St. Lawrence or the territorial seas. In 1901 the population was 1,648,898, 992,667 being classed as rural and 666,231 as urban. Since 1891 the rural population has increased but little, but there has been a growth of about 11% in the population of the towns and cities. No province has taken so small a share in the development of the West. True to his ancestral instincts, the French-Canadian remains close to the place of his birth. If he emigrates, it is to the neighbouring cities of New England or to the eastern districts of the province of Ontario. On the other hand, in the rural parts of the province, the French are driving out the English-speaking settlers, especially in the south-western counties, settled by Loyalists at the close of the War of American Independence, and known as the Eastern Townships. Nearly 98% of the population are Canadian-born. Of these over 80% are of French descent; of the remainder about 7% are English, 7% Irish and 4% Scots. Save to the city of Montreal there is little immigration; but so prolific are the French that the population of the province increases as fast as that of the rest of the Dominion, in which to the natural increase is added a large immigration. The census gives the number of the average family as 5.36, but families with twelve and eighteen children are not uncommon. The English-speaking population is almost wholly confined to the towns, especially Montreal, in which city it controls the chief shipping and commercial interests. Of the original inhabitants about 5000 Indians remain, chiefly on reserves in the neighbourhood of Montreal and Quebec. Though quite peaceful, they are on the whole less civilized than those of eastern and southern Ontario. The capital is Quebec, with a population of about 70,000, which increases but slowly. The largest city is Montreal, the commercial and shipping centre of the Dominion, at the head of ocean steamship navigation, with a population of about 350,000. Other cities are Hull (practically a suburb of Ottawa; pop. in 1901, 13,993); Sherbrooke (11,763); Three Rivers (9981); Lévis (7785).

The French, Irish and Indians are almost entirely of the Roman Catholic faith; a majority of the English are Anglican, with some Methodists; the Scots are Presbyterian. The Roman Catholic Church enjoys extensive rights and privileges, and nowhere in the world is devotion to that faith more widespread or more unquestioning.

**Administration.**—As in all the provinces, the executive power is nominally vested in a lieutenant-governor, appointed for five years by the federal government, and assisted by an executive council (or cabinet) who have seats in, and are responsible to, the local legislature. In reality the lieutenant-governor is a figure-head, and power is in the hands of the legislature, which consists of two houses, a Legislative Council, appointed nominally by the lieutenant-governor, really by the premier, and an Assembly, chosen by what is practically manhood suffrage. Either French or English may be used in addressing either house. The municipalities have large powers of local government, which are used with more or less efficiency, the predatory tendencies of the ward-politician being sometimes apparent, though of late years an improvement has been effected. The finances of the province are drawn from the same sources as those of Ontario (q.v.). Their administration has not been so economical as in the sister province, and there is a net provincial debt of over $4,000,000.

**Education.**—In primary education Quebec is still behind the other provinces, but great progress has been made since Federation; illiteracy is decreasing, and 80% of the population over five years of age can read and write. The Council of Public Instruction is a body nominated by the province, to which the school boards are nominally responsible. In the Roman Catholic schools the teachers are controlled by the clergy, the episcopate, or officio, one-half of the Catholic section of the council. In the cities of Quebec and Montreal the schools are efficient and the teachers well paid; but in the rural parishes and other distant districts the schools, though often inadequate, the buildings being poor, and the teachers receiving a mere pittance, in some cases less than $30 per annum. Over 95% of the teachers in the primary schools are women. The government has charged by law the control of third by laws, and there are also a number of independent schools, primary and secondary, usually under religious control; of these the so-called "Collèges Classiques," supported by the Catholic Church, are the most important. The chief universities are Laval School (founded 1854), at Montreal (founded 1820), and Laval (Roman Catholic) (founded 1852), with its headquarters at Quebec, and with a large branch at Montreal. (See MONTREAL and QUEBEC CITY.) There is also a small Anglican university, that of Bishop's College, Lennoxville (founded 1851), in connection with which the McGill University (founded 1829), at Montreal, and the Université Laval (founded 1852), with its headquarters at Quebec, and with a large branch at Montreal. (See MONTREAL and QUEBEC CITY.)

**Agriculture.**—Quebec is not a prosperous province, though somewhat unprogressive farmer, and loves the land with an even greater attachment than do the peasants of old France. Till recently his agriculture was of a very domestic character. He grew enough grain for his own consumption, including oats, wheat, and rye, and some flax and hemp. His cattle were mostly dairy sheep or cattle, which were ground into flour for the home consumption. His butter was of moderate quality. Now, however, the provinces of Ontario and Quebec are making good butter. The government is promoting the raising of dairy cattle and the production of butter. The most promising industry is the production of maple sugar and syrup. The government is promoting this industry. At first of a coarse character, it is improving in quality.

The total value of the agricultural produce of the province is about $10,000,000, about half that of Ontario. Several agricultural and dairy schools are supported or assisted by the provincial government. A great deal of good is being done by the Agricultural College at Ste Anne de Bellevue.

The province still possesses large areas of crown land, which is sold at a nominal price to bona fide settlers. In the northern part of the province some of the cleared and rail-less areas have been opened up by the Grand Trunk Pacific railway.

**Forests.**—Next to agriculture in importance are the various industries which depend on the products of the forest. Over 150,000,000 acres of forest land are still uncleared, chiefly in the northem part of the province, though the best timber is said to grow south of the watershed. In the north, pine, spruce, and fir predominate, and, farther south, the maple: spruce, lime (linde), basswood, etc.
**QUEBEC**

*Tilia Americana* and poplar, are used extensively in the making of paper pulp. The annual value of the wood cut in the province is about £4,000,000, rather less than that of Ontario, and not quite two-fifths that of the whole Dominion. An export duty is levied on all wood exported.

**Fur and Fish.**—The value of the annual catch of fish is estimated at £150,000, most of which consists of the product of the cod and herring fisheries in the St Lawrence. From Isle Vert eastward almost all the settlers along the most elevated stretches of the river are connected by the Sillery Canal. It is carried on mainly in small boats, which put out in the morning and return at nightfall, few large vessels being employed. Throughout the province are numerous trout-streams, and many of the northern lakes are well supplied with trout and other fresh-water fish. In Lake St John is caught the *Oreina*, a land-locked salmon growing to the size of six or eight pounds, and well known to anglers. Moose, deer, bear and other animals provide excellent shooting in the Laurentian mountains, and a variety of birds in the forests.

**Manufactures.**—In manufactures Quebec ranks second among the provinces, Ontario coming first. The largest manufacturing town is Montreal, where most of the industries are controlled by the English-speaking minority. No other part of the Dominion is so rich in water power, which is provided to a limitless extent by the falls of the rivers Montmorenci, de la Chaudière (Shawinigan Falls), and St Anne, the rapids on the St Lawrence and the Richelieu, and many smaller streams. The manufacture of paper and paper pulp is a large industry. A number of the factories are situated in the rich lumber districts along the St Lawrence river.

**Communications.**—The rivers were long the chief roads, by water in summer, over the ice in winter; but though the rivers are still used, the bulk of travel and of transport is now done by rail. The first railway in Canada was built in 1830 to carry stone from the wharves to aid in the construction of the citadel of Quebec. The first passenger railway was built in 1839 between LaPrairie on the St Lawrence river and St John's on the Richelieu. There is now good railway communication between all the chief points, and branch lines are opening up new areas to settlement. While a few main roads are kept in good condition by the provincial government, many of the others are merely provided with cinders, and, in consequence of the heavy rains, are impassable in winter. The whole of the inter-provincial roads are the responsibility of the Dominion government.

**Bibliography.**—The various departments of the provincial government publish annual reports on a great variety of subjects. The annual *Canada Year Book*, published by the Federal Government, contains much information in a tabular form. Interesting articles are contained in *J. Castell Hopkins, Canada; an Encyclopaedia* (Toronto, 1898-1900). The legal enactments in which the municipal system is embodied are found in the Revised Statutes of the province; they were first read in 1774. The Revised Statutes of 1870 have been revised and are entitled *Le Canada; les deux races* (1903; translated into English under the title of The Race Question in Canada, 1906), is well-informed and impartial.

QUEBEC, the capital of the Canadian province of the same name, is situated on the north bank of the river St Lawrence, at its junction with the St Charles, about 300 m. from the gulf of St Lawrence and 180 m. by river N.E. of Montreal, in 41° 12' 19" W. and 46° 48' 17" N. The origin of the name Quebec has been much disputed, but it is apparently the Algonkian word for a strait, or sudden narrowing, the river at its junction with the St Charles being about 2500 yds. wide, but narrowing opposite Cape Diamond to 1314.

Quebec is situated on the elevated tableland which forms the left bank of the St Lawrence for a distance of 8 m. The highest part of the headland is Cape Diamond, 333 ft. above the level of the water, and crowned by the citadel; towards the St Lawrence it presents a bold and precipitous front, while on the landward side and towards the St Charles the declivity is more sloping and gradual. The harbour of Quebec is spacious and deep enough to hold the largest ships, and, with the Louise basin and Lorne graving-dock,—the latter on the opposite shore at Lévis,—forms one of the best harbours in America. It is usually open from the end of April to the middle of December, being closed by ice during the winter. The Louise basin consists of twin wet-docks and tidal harbours, with areas of 40 and 20 acres respectively, and a minimum depth of 26 ft. The harbour is protected towards the north-east by the island of Orleans, on either side of which there is an approach, though that to the north of the island is used only by small vessels. The spring tides rise and fall about 18 ft. Quebec is divided into upper and lower town,—access to the former being obtained by steep and winding streets, by several flights of narrow steps, or by an elevator. Much of the lower town still recalls the older portions of such French provincial towns as Rouen or St Malo. The streets, with one or two exceptions, are narrow and irregular; but it remains the principal business quarter of the city. In the upper town, where the streets are wider and well paved, are the better class of dwelling-houses and public buildings, most of the churches, the public walks and gardens, and many of the retail shops. To the west are the suburbs of St John and St Roch. The latter occupies the lower plain, and is of some commercial importance; the former is on the same level as the upper town. South-west of St John stretch the historic Plains of Abraham. On this battleground stands a simple column 40 ft. high, marking the spot where General Wolfe fell. It was erected in 1849 by the British army in Canada, to replace a monument erected in 1832 by the governor-general, Lord Aylmer, which had been broken and defaced by ruffians. Till 1908 the Plains were also disfigured by a gaol and rifle factory, but these have been removed, and the battleground converted into a public park. In the gardener's garden, which overlooks the St Lawrence, is a monument 65 ft. in height, erected in 1828 under the administration of Lord Dalhousie, dedicated to the memory of Wolfe and Montcalm. An iron pillar surmounted by a bronze statue, the gift of Prince Jerome Napoleon, stands on the Ste Foy road, and was erected in 1855-60 to commemorate the achievements of the British and French troops in the brilliant but fruitless French victory of April 28, 1760. The chief point of interest in the upper town is Dufferin Terrace, a magnificent promenade overlooking the St Lawrence, 1400 ft. long and 200 ft. above the level of the river. Part of this terrace occupies the site of the old Château St Louis, which was destroyed by fire in 1834. At the eastern end of the terrace stands a fine statue of Champlain, erected in 1898. Near by, and conspicuous from the river, is the Hotel Frontenac, erected by the Canadian Pacific railway on the model of an old French château. Nothing remains of the fortifications erected under the French régime. The present walls and the citadel, which covers an area of about 40 acres, were built in 1823-32 at a cost of over £7,000,000. Since then, several of the gates have been destroyed, and others rebuilt, but in other respects the walls are practically intact, and, though obsolete as fortifications, add greatly to the picturesque beauty of the city. Between 1865 and 1871 three forts were built on the Lévis side of the river, but were neither manned nor armed. Quebec's natural position still makes it one of the great military strength, though depending on naval control of the sea and of the gulf of St Lawrence.

Besides numerous Protestant churches, including a small Anglican cathedral, there is a Jewish synagogue; but the bulk of the population is Roman Catholic. The cathedral, founded in 1647, and enlarged at intervals, is a large but not very striking building in the upper town. It contains some good oil paintings and some much-prized relics, but is rather rich in its ornamentation. Of the numerous other churches, the most interesting is Notre Dame des Victoires, in the lower town, erected in 1688, and named in honour of the defeat of the ships in 1690 and the shipwreck of Sir Hovenden Walker in 1711. Laval University, which derives its name from François de Montmorency Laval, the first bishop of Quebec, who founded in 1663 a seminary for the training of priests, is under strict Roman Catholic control. It was instituted in 1852 by a royal charter from Queen Victoria and in 1876 received a charter from Pope Pius IX. The building is large and spacious, and the university includes faculties of theology, law, medicine and arts, a library of 125,000 volumes, a museum and a picture gallery. A large branch of the university has been established at Montreal, and has often, but vainly, sought permission to become an independent Catholic university. In connexion with Laval are the grand seminary founded in 1663, where theology is taught, and the minor seminary for literature and
philosophy. Other Roman Catholic institutions are Laval Normal and Model School, the Ursuline Convent, the Convent of the Good Shepherd and several nunneries. The convent and church of the Ursulines, founded in 1641, contains nearly 100 nuns and lay sisters, and nearly 600 pupils. It possesses some excellent paintings and a number of relics, among which is the skull of the French general, Montcalm. Morrin College, founded in 1839 by Dr Morrin, was for some years an efficient college in arts and theology, under Presbyterian control, but is now defunct. High schools for boys and girls and numerous academies are supported by the Protestants, under the dual system of education in the province. The Literary and Historical Society—the oldest chartered institution of the kind in Canada, founded by Lord Dalhousie in 1824—the Canadian Institute, the Geographical Society, the Young Men's Christian Association, the Advocates' Library and the Parliamentary Library, have valuable collections of books, the latter containing 70,000 volumes, and numerous MSS. chiefly relating to the early history of the province. The principal benevolent institutions are the marine hospital, the Hôtel Dieu, founded in 1639 by the duchess of Aiguillon, the general hospital (1663), the Jeffrey Hale Hospital, and the lunatic asylum at Beauport controlled by the Grey Nuns (sisters of charity). The provincial parliament buildings, erected in 1878-92, are situated in extensive grounds on Grande Allée. The main building is quadrangular in form, and is ornamented with numerous statues. The seat of the lieutenant-governor is at Spencerwood, a pleasant country estate outside the city. Other prominent buildings are the palace of the Roman Catholic Archbishop, which adjoins Laval University, the court house, post office, custom house, city hall (1890–95) and masonic hall. Quebec is well lighted with gas and electric light, and has a system of electric trams cars, a plentiful supply of power being obtained from the Montmorency Falls (266 ft. in height), 6 m. N.E. The climate is severe, but bracing, the mean temperature in winter being 10°, in summer 68°, and the mean of the year 39°. The main lines of the Grand Trunk, Canadian Pacific and intercolonial railways are on the south bank of the St Lawrence, but branch lines connect the city with Montreal, and in headquarters of the Quebec and Lake St John, and various smaller railways. Steam ferries connect the city with Lévis on the opposite bank, but the project of a bridge, though of great importance to the city, has been in various ways delayed. In August 1907 the portion completed fell into the St Lawrence.

The city returns three members to the Canadian House of Commons, and three to the Provincial House of Assembly. It is governed by a mayor and council of aldermen, who hold office for two years, and are usually re-elected, one mayor having held office for eleven successive years. Quebec is the seat of a Roman Catholic archbishop and of an Anglican bishop. Economically, Quebec was long the chief port of Canada. A series of strikes almost ruined its export trade, and numerous severe fires, of which that of 1845 was the chief, also lessened its importance. For many years the export trade passed almost entirely to Montreal, but the increasing size of seagoing vessels makes navigation above Quebec more and more difficult, especially for fast passenger steamships, and for such vessels Quebec is again becoming the terminus. Quebec's staple export is timber, the greater portion of which comes from the Ottawa and St Maurice districts. Formerly the rafts floating down the river were collected in the coves which extend along both sides of the river, above the city, and were fastened by booms along the banks. Now much of the timber is sent by rail. On the right bank of the stream, not far from Quebec, are extensive sawmills. Deals and square timber form the bulk of the export, but some furniture is also sent, and an increasing quantity of wheat is shipped. The building of wooden ships was formerly one of the chief industries of Quebec. The principal manufactures are iron castings, machinery, cutlery, nails, leather, rifles, gunpowder, musical instruments, boots and shoes, paper, India-rubber goods, ropes, tobacco, steel. The population increases but slowly, having risen from 59,690 in 1871 to 68,840 in 1901; of these over 60,000 are French and Roman Catholic.

The first known white man to visit Quebec was Jacques Cartier, the French navigator, in 1535, who found on the site a large Indian village, called Stadacona. In July 1608 the present city was founded, and named by Champlain. Its growth was slow, and in 1620 it had but two permanently settled families, with a shifting population of monks, officials and fur traders. In that year it was captured by the English under Sir David Kirke (1597–1636; see H. Kirke, The First English Conquest of Canada, London, 1871, reprinted 1908), but in 1623 it was restored to the French by the treaty of St Germain-en-Laye. In 1663 the colony of New France was created a royal province, and Quebec became the capital. In 1690 Sir William Phips, governor of Massachusetts, attempted to reconquer it with a fleet and army fitted out by New England, but was defeated by the French governor, Frontenac. In 1711 a great British expedition sent against it under Sir Hoven
den Walker was shipwrecked in the gulf of St Lawrence, and the French held possession till 1759 (see below), when it was captured by the British troops on the 18th of September, five days after the battle of the Plains of Abraham; it was finally ceded to Great Britain by the treaty of Paris in 1763. In 1775 the American generals Montgomery and Benedict Arnold attacked the city, but Montgomery was killed (December 31, 1775) and Arnold was compelled to retreat in the following spring.

In 1763–1841, in 1851–55, and in 1859–65 Quebec was the capital of Canada, and it is still its most historic and picturesque city.

Wolfe's Quebec Expedition, 1759.—Both in itself and also as the central incident of the British conquest of Canada, the taking of Quebec is one of the epics of modern military history. The American campaigns of the Seven Years' War, hitherto that spasmodic, were, after Amherst's capture of Louisburg in 1758, co-ordinated and directed to a common end by that general, under whom James Wolfe, a young major-general of thirty-three years of age, was to command an expedition against Quebec from the lower St Lawrence, while Amherst himself led a force from New England by Lake Champlain on Montreal. Wolfe's column consisted of about 7000 troops, and was convoyed by a powerful fleet under Admiral Saunders. The expedition sailed 300 m. up the St Lawrence, disembarked on the Isle of Orleans and encamped facing the city. The defenders were commanded by Montcalm, a soldier whose character and abilities, like Wolfe's, need no comment here. The French were superior in numbers, though a considerable part of their force was irregular; but they had the defender's difficult task of being strong everywhere. Wolfe began the attack by seizing Point Lévis, and thence bombarding Quebec. This, however, affected the main defences of the upper city but little, and they were moreover protected from closer attack by the St Lawrence and the St Charles. The third side of the triangle was the "plains of Abraham," to which it was thought there was no approach from the river. After wasting some weeks, therefore, Wolfe decided to cross the St Lawrence 7 m. below Quebec and to fight his way to the city by the St Charles side. But Montcalm's fortified posts spread out from Quebec through Beauport as far as the Montmorency, and this formidable obstacle checked the English advance at the outset. No artifice could lure the defenders away, and at last Wolfe attacked the line of the Montmorency and was repulsed with heavy loss (July 31). Wolfe's fragile health gave way under the disappointment, and despondency set in in the English camp. But as soon as the young leader had recovered a little, he summoned his braggadics and worked out a plan for attacking by the upper waters and the heights of Abraham. Access to the heights could be obtained, it was
found, by a tiny cove (Wolfe's cove), from which a steep footpath led to the summit. It was no place for artillery, and even for infantry the climb was long and exhausting, but the attempt was made. Considered as a way of taking Quebec, it was in the last degree a forlorn hope, but Wolfe, as a true soldier, felt the imperative necessity of preventing his opponent from sending reinforcements to the force opposing Amherst, and staked everything upon achieving this at least. "Happy if our efforts here," as he wrote, "can contribute to the success of His Majesty's arms in any other part of America." What with losses in action and by sickness, and detachments to guard the camps and batteries, only 3600 men could be spared for the attempt. These embarked on the warships on the evening of September 12, and sailed up stream. The watchful Montcalm sent a detachment to observe their movements, but the ships proceeded to a point well above the cove, luring the detachment out of the way. Then at 1 a.m. Wolfe, with half his force, dropped down stream in the boats of the squadron and landed. The path was guarded by a redoubt, but the light infantry which led the advance scarcely attempted to follow her scrambling up the hillside wherever they could find a foothold. The garrison of the redoubt, startled by the unforeseen attack, abandoned the work, and by daylight Wolfe had assembled his 3600 men on the plains above the city. Montcalm meanwhile had been held in check by a demonstration of part of the fleet under Admiral Saunders on Beauport, but at last, realizing that the real attack was coming from the other flank, he hurried all the troops he could collect over the St Charles and drew them up on the plain, with their backs to the walls of the upper town. He took the offensive at once. He had plenty of militiamen and irregulars, and these rapidly drove the British light infantry on to their main body, which was threatened on both flanks. On so small a battlefield, the troops in Wolfe's line of battle quickly became aware that the enemy was attacking in superior force. But their leader steadied them by his personal example, and when the French came within close range one "perfect volley" from the whole line decided the battle. Then as the French stopped, with great gaps in their lines, Wolfe led on his men to complete the victory. He received two painful wounds and then a shot through the breast. His last order, one rare indeed in the annals of 18th-century fighting, was to send a force to the St Charles bridge to cut off the retreat of the French. Montcalm too was mortally wounded, and died next day. On the 18th of September Quebec surrendered.  

**QUEBEC ACT.** The title usually given to a bill introduced into the House of Lords on May 2, 1774, entitled "An Act for making more Effectual Provision for the Government of the Province of Quebec, in North America." It passed the House of Lords on May 17, was discussed in the Commons from May 26 to June 13, and finally passed with some amendments. These were accepted by the Lords, in spite of the opposition of Lord Chatham, and the bill received the royal assent on June 22. The debates in the House of Commons are not found in the Parliamentary History, but were published separately by J. Wright in 1839. The speech of Lord Chatham is given in the Chatham Correspondence (iv. 351-353).  

By this act the boundaries of the Canadian province of Quebec were extended so as to include much of the country between the Ohio and the Mississippi. The French inhabitants of the province were granted the liberty to profess "the religion of the Church of Rome"; the French civil law was established, though in criminal law the English code was introduced. Government was vested in a governor and council, a representative assembly not being granted till the Constitutional Act of 1791.  

The granting of part of the Western territory to Quebec, and the recognition of the Roman Catholic religion, greatly angered the American colonies. On the other hand, it did much to keep the French Canadians from joining the Americans in the coming struggle. The act is still looked back to by the French in Canada as their great charter of liberty.  

**QUEBEC,** a town of Germany in the Prussian province of Saxony, situated on the Bode, near the N.W. base of the Harz Mountains, 12 miles S.E. by rail from Halberstadt on the line Magdeburg-Thale. Pop. (1905) 24,798, almost all Protestants. It consists of the old town, which is still partly surrounded by a turreted wall, the new town and four suburbs. On the west it is commanded by the castle, formerly the residence of the abbesses of Quedlinburg, connected with which is the interesting Schlosskirche, which was dedicated in 1129 and completely restored in 1862-82. The German king, Henry the Fowler, his wife Matilda, and Aurora, countess of Königsmark, the mistress of Augustus the Strong, are buried in the Schlosskirche. There are many interesting articles in the treasury. The Gothic town hall, a 14th-century building, restored and enlarged in 1900, contains a collection of antiquities, and near it stands a stone figure of Roland. The town also possesses a gymnasium founded in 1540 and now containing the abbey library and a municipal museum. It has a fine memorial of the war of 1850-71. Quedlinburg is famous for its nurseries and market gardens, and exports vegetable and flower seeds to all parts of Europe and America. Its chief manufactures are iron goods, machinery and cloth, and it has a trade in grain and cattle. Near the church is St Wipertus, which dates from the 12th century, and has a crypt of the 10th century.  

Quedlinburg was founded as a fortress by Henry the Fowler about 922, its early name being Quitlingen. Soon it became a favourite residence of the Saxon emperors and was the scene of several diets. It afterwards joined the Hanseatic League. The abbey of Quedlinburg was planned by Henry the Fowler, although its actual foundation is due to his son Otto the Great. It was a house for the daughters of noble Saxon families and was richly endowed, owning at one time a territory about 40 sq. m. in area. The abbesses, who were frequently members of the imperial house, the second of them being Otto's daughter Matilda, ranked among the princes of the empire, and had no ecclesiastical superior except the pope. The town at first strove vigorously to maintain its independence of them, and to this end invoked the aid of the bishop of Halberstadt. In 1477, however, the abbess Hedwig, aided by her brothers, Ernest and Albert of Saxony, compelled the bishop to withdraw, and for the next 200 years both town and abbey were under the protection of the elector of Saxony. In 1539 the townsmen accepted the reformed doctrines and the abbey was converted into a Protestant sisterhood. In 1697 the elector of Saxony sold his rights over Quedlinburg to the elector of Brandenburg for 240,000 thalers. The abbesses, however, retained certain rights of jurisdiction, and disputes between them and the Prussian government were frequent until the secularization of the abbey in 1803. The last abbess was Sophia Albertina (d. 1820), sister of King Charles XIII. of Sweden. After forming for a few years part of the kingdom of Westphalia, the abbey lands were incorporated with Prussia in 1815.  

See the *Urkundenbuch der Stadt Quedlinburg*, edited by Jancke (Halle, 1873-82;): Ranke and Kugler, Beschreibung und Geschichte der Schlosskirche zu Quedlinburg (Berlin, 1838); Lorenz, *Alt-Quedlinburger Geschichte* (1858-1868) (Halle, 1873); Huchs, *Führer durch Quedlinburg*. For the history of the abbey see Fritsch, *Geschichte des Reichsstifts und der Stadt Quedlinburg* (Quedlinburg, 1828).  

**QUEEN (O.E. cwne, wife, related to "queen," O.E. cwene, a hussy; cf. Gr. γυνή: from root γυν-, to produce; cf. genus, "kin, &c.", the title of the consort or wife of a king ("queen consort"), or of a woman who is herself the sovereign ruler of a state ("queen regnant"); the widow of a former reigning sovereign is a "queen dowager," and, when the mother of the reigning sovereign, a "queen mother."**  

For the position of the queen in English constitutional law see CONSORT, and for her duties, see HOUSFORM, ROYAL.  

**QUEEN ANNE'S BOUNTY,** the name applied to a perpetual fund of first-fruits and tithes granted by a charter of Queen Anne, and confirmed by statute in 1705 (2 & 3 Anne, c. 11), for the augmentation of the livings of the poorer Anglic
QUEENBOROUGH—QUEENSBERRY

clergy. First-fruits (annates) and tenths (decimes) formed originally part of the revenue paid by the clergy to the papal exchequer. The former consist of the first whole year's profit of all spiritual preferments, the latter of one-tenth of their annual profits after the first year. In accordance with the provisions of two acts (5 & 6 Anne, c. 24, and 6 Anne, c. 27) about 3500 poor livings under the annual value of £50 were discharged from first-fruits and tenths. The income derived from first-fruits and tenths was annexed to the revenue of the crown in 1532 (26 Hen. VIII. c. 3), and so continued until 1703. Since that date there has been a large mass of legislation dealing with Queen Anne's Bounty, the effect of which will be found set forth in a Report of a Joint Select Committee on the Queen Anne's Bounty Board, 1900. The governors consist of the archbishops and bishops, some of the principal officers of the government, and the chief legal and judicial authorities. The augmentation proceeds on the principle of assisting the smallest benefices first. All the cures not exceeding £10 per annum must have received £200 before the governors can proceed to assist those not exceeding £30 per annum. In order to encourage benefactions, the governors may give £200 to cures not exceeding £45 a year, where any person will give the same or a greater sum. The average income from first-fruits and tenths is a little more than £16,000 a year. In 1906 the trust funds in the hands of the governors amounted to £7,023,000. The grants in 1906 amounted to £28,607, the benefactions to £29,888. The accounts are laid annually before the king in council and the houses of parliament. The duties of the governors are not confined to the augmentation of benefices. They may in addition lend money for the repair and rebuilding of residences and for the execution of works required by the Ecclesiastical Dilapidations Acts, and may receive and apply compensation money in respect of the enfranchisement of copyholds on any benefice. The governors are unpaid; the treasurer and secretary receives a salary of £1000 a year. He is appointed by patent under the great seal, and holds office during the pleasure of the crown.

QUEENBOROUGH, a municipal borough in the Faversham parliamentary division of Kent, England, in the Isle of Sheppey, close to the junction of the Swale and Medway, 2 m. S. of Sheerness on the South-Eastern & Chatham railway. Pop. (1901) 1544. The prosperity of the town has been revived in modern times by the establishment by the railway company of a branch line from Sittingbourne in connexion with a service of mail and passenger steamers to Flushing (Holland), which run twice daily. The first copperas factory in England was established at Queenborough in 1579, by Matthias Falconer, of Brabant. In 1850 Portland cement works were built, and there is a large trade in timber. The town is governed by a mayor, 4 aldermen and 12 councillors. Area, 302 acres.

A fortress, called Sheppey Castle, is said to have existed from an early period for guarding the passage of the Swale river. Queenborough Castle was built about 1361 by Edward III., who named it after Queen Philippa and made it a free borough, with a governing body of a mayor and two bailiffs. Charters were granted by subsequent sovereigns down to Charles I., who re-incorporated the town under the title of the mayor, jurats, bailiffs and burgesses of Queenborough. The castle never had any military history, and having been seized by parliament together with the other royal possessions, and being considered of insufficient importance for repair, was demolished during the Commonwealth. The borough subsequently decreased in importance. The chief part of the population were employed in the oyster fishery. The town was first represented in parliament by two members in 1522; it lost its franchise by the Reform Act of 1832.

QUEEN CHARLOTTE ISLANDS, a compact group lying off the northern part of the coast of British Columbia, and forming part of that province of Canada. Geologically the group is composed mainly of Triassic, Cretaceous and Tertiary strata, penetrated by intrusive rocks. It occupies a position similar to that held by Vancouver Island farther to the south, in regard to the mainland coast and its immediately adjacent islands, but is separated by a somewhat wider sea from the coast. It was named by Captain Dixon, who visited the islands in the "Queen Charlotte" in 1787. Although the islands promise to become important, because of their excellent harbours, the discovery of good seams of bituminous coal (beside the anthracite already known), their abundant timber of certain kinds and their prolific fisheries, but little settlement has taken place. The wonderfully productive halibut fisheries of Hecate Strait, which separates these islands from the mainland and its adjacent islands, have attracted the attention of fishing companies, and great quantities of this fish are taken regularly and shipped across the continent in cold storage. The natives, the Haida people, constitute with little doubt the finest race, and that most advanced in the arts, of the entire west coast of North America. They had developed in its highest degree the peculiar conventional art of the north-west coast Indians, which is found in decreasing importance among the Tsimsians on the west, the Tlingit on the north and the Kwakiutl and other tribes farther south on the Pacific coast. The carved totem posts of the Haida, standing in front of the heavily framed houses, or at a little distance from them, represent the coats of arms of the respective families of the tribes and generally exhibit designs treated in a bold and original manner, highly conventionalized but always recognizable in their purport by any one familiar with the distinctive marks of the animal forms portrayed. These primitive monuments are, however, rapidly falling to decay, and the people who erected them are becoming reduced in number and spirit. The native population of the islands is less than 700. (F. D. A.)

QUEENSBERRY, EARLS, MARQUESSES AND DUKES OF. The Queensberry title, one of the many with which the Scottish house of Douglas is associated, originated in the creation of Sir William Douglas (d. 1640) as earl of Queensberry in 1633. He was the eldest son of Sir James Douglas of Drumlanrig (d. 1616). His grandson William, the 3rd earl (1637-1693), was created marquess of Queensberry in 1682 and duke of Queensberry in 1684; he was lord justice general and an extraordinary lord of session. He was also lord high treasurer of Scotland, and served James II. as lord high commissioner to the parliament of 1685, but in 1686 he was deprived of his offices. He had assented to the accession of William and Mary and had again enjoyed the royal favour before he died on the 28th of March 1695. His son James Douglas, the 2nd duke (1662-1711), was born at Sanquhar Castle on the 18th of September 1662, and was educated at the university of Glasgow, afterwards spending some time in foreign travel. At the Revolution of 1688 he sided with William of Orange and was made a privy councillor; after he had become duke of Queensberry in 1693 he was appointed an extraordinary lord of session and keeper of the privy seal. He was the royal commissioner to the famous Scottish parliament which met in 1700, and just after the accession of Anne in 1702 he was made one of the lords spiritual for Scotland. In 1714, while his son was on the continent, he was, by reason of some event, suspected of being a Jacobite intrigueur, and was sent to the Tower, and was thereafter received very ill by his opponents. The crown was under a temporary cloud through his connexion with the Jacobite intrigueur, Simon Fraser, Lord Lovat, who had utilized Queensberry's jealousy of the duke of Atholl to obtain a commission from him to get evidence in France which would implicate Atholl. The plot was betrayed by Robert Ferguson, and Queensberry was deprived of his offices. However, in 1705 he was restored and in 1706 he was again commissioner to the Scottish parliament; in this capacity he showed great ability in carrying through the treaty for the union of the two crowns, which, chiefly owing to his influence and skill, was completed in 1707. For this he was very unpopular in Scotland, but he received a pension of £3000 a year. In 1708 he was created duke of Dover and marquess of Beverley, and he obtained a special remainder by which his titles were to pass to his second surviving son Charles, and not to his eldest son James, who was an idiot. In February 1709 he was appointed third secretary of state, and he died on the 6th of July 1711.
Charles Douglas, the 3rd duke (1668–1778), who had been created earl of Solway in 1706, was lord justice general from 1763 until his death in October 1778. In 1720 he married Catherine, daughter of Henry Hyde, 4th earl of Clarendon; this lady, a famous beauty, although very eccentric, was the friend of many of the wits and writers of her day, notably of Gay, Swift and Walpole. She died on the 17th of July 1777. Their two sons predeceased the duke, and when he died his British titles, including the dukedom of Dover, became extinct, but the Scottish titles passed to his cousin, William, 3rd earl of March (1724–1810).

This William Douglas, who now became the 4th duke of Queensberry, is best known by his sobriquet of “Old Q.” On the turf he was one of the most prominent figures of his time, and his escapades and extravagances were notorious. From 1766 to 1776 he was vice-admiral of Scotland, and in 1760 he was made a lord of the bedchamber in George III; but later he was an associate of the Prince of Wales, being removed from his office in the royal household in 1789. A generous patron of the stage and of art, he was to the end of his life a “noble sportsman” of the dissolute type, and his degeneracy was the theme both of Wordsworth and of Burns. He died unmarried, but not without children, in London on the 23rd of December 1810. The dukedom of Queensberry and some of his other titles, together with his fine seat Drumlanrig Castle, now passed to Henry Scott, 3rd duke of Buccleuch, in whose family they still remain; but the marquessate of Queensberry descended to Sir Charles Douglas (1777–1837), the representative of another branch of the Douglas family, who became the 5th marquess.

John Sholto Douglas, 8th marquess of Queensberry (1854–1900), son of Archibald William, the 7th marquess (1818–1858), became a well-known patron of sport and particularly of pugilism. He helped to found the Amateur Athletic Club in 1860, and the new rules for prize-fighting, drawn up in 1867, were called after him the “Queensberry Rules.”

He married the daughter of Alfred Montgomery, and was succeeded by his son, Percy Sholto, 9th marquess (b. 1868).

QUEENSLIFF, a town of Grant county, Victoria, Australia, 68 m. by land and 32 by sea S.W. by S. of Melbourne. Pop. (1901) 2025. It lies on Shortlands Bluff, a small peninsula connected with the mainland by the Narrows, a contracted strip of land some 400 yds. broad. Queenscliff is a favourite watering-place, having a fine pier and excellent and safe seabathing. It is also a pilot station; and the quarantine station for vessels entering Port Phillip is near the town.

QUEENS COUNTY, a county of Ireland, in the province of Leinster, bounded N.W. and N. by King’s County, E. by Kildare, S. by Carlow and Kilkenny, and W. by Tipperary; area, 424,733 acres, or about 66 sq. m. The surface is for the most part level or gently undulating, but in the north-west rises into the elevations of the Slieve Bloom Mountains, the highest summit being Arderin, 1733 ft. In the central part of the county there is a large extent of bog. The south-east portion is included in the Leinster coalfield. Nearly the whole of the county is drained either by the Barrow, which has its source in the Slieve Bloom Mountains, and forms at various points the boundary with King’s County, Kildare and Carlow, or by the Nore, which enters the county from Tipperary near Borris-in-Ossory, and flows east and then south till it reaches Kilkenny. The lakes are few and small, the largest being Lough Anaghmore on the north-western boundary. The Grand Canal enters the county at Portarlington, and runs southwards to the Barrow in Kildare, a branch passing westwards 12 miles to Mountmellick.

The limestone plain prevails in this county, but the high coalfield, shared with Kilkenny and Carlow, rises from it in the south; while the Slieve Bloom Mountains, a round-backed Old Red Sandstone mass with Silurian inlets, dominate the lowland west of Maryborough. The limestone itself produces a range of hills near Stradbally, on which the fortress of Dunamase stands conspicuously. Esker-gravels provide sandy soils in many places. Clay-ironstone was formerly raised in connection with the anthracite from the coalfield.

The climate is dry and healthy. Originally a great extent of the surface was occupied with bog, but by draining much of it has been converted into good land. For the most part it is very fertile except in the hilly districts towards the north, and there is some remarkably rich land in the south-east. The acreage under pasture is not quite twice that of tillage. Dairy-farming is extensively practised. Agriculture forms the chief occupation, but the manufacture of woolen and cotton goods is carried on to a small extent. The main line of the Great Southern & Western railway traverses the county from N.E. to S.W. by way of Portarlington and Maryborough; from the latter town branches run N. to Mountmellick and S. to Waterford, and from Ballybrophy a line runs W. to Birr (Parsonstown) and to Limerick.

The population (63,855 in 1801; 57,417 in 1901) decreases in excess of the average of the Irish counties, and emigration is considerable. Of the total about 88% are Roman Catholic, and almost the whole is rural. Maryborough (the county town, pop. 2957), Mountmellick (2497) and Mountrath (1304), with Portarlington (1943, partly in King’s County), are the principal towns. The county is divided into eleven baronies. Ecclesiastically it is in the Protestant dioceses of Dublin, Killaloe and Ossory, and in the Roman Catholic dioceses of Kildare and Leighlin, Ossory and Killaloe. Assizes are held at Maryborough, and quarter sessions at Abbeyleix, Borris-in-Ossory, Graigue (a suburb of Carlow), Maryborough, Mountmellick and Stradbally. The county is divided into the Leix and Ossory parliamentary divisions. To the Irish parliament two members were returned for the county and two each for the boroughs of Ballinakill, Maryborough and Portarlington.

The territory now included in Queen’s County covered the districts of Leix, Sluwmargy, Itry and part of Glenmally; until in 1660 they were made up the name of Queen’s County, in honour of Queen Mary, the place chosen for the county town being named Maryborough. Three miles south of Stradbally is Dun of Clopock, an ancient dun or fort occupying the whole extent of the hill. Aghaboe, where there are the ruins of the abbey, was formerly the seat of the bishopric of Ossory. There are no remains of the abbey of Timahoe founded by St Mochua in the 6th century, but in the neighbourhood there is a fine round tower, 96 ft. high. Abbeyleix, a small market town south of Maryborough, had a famous Cistercian foundation of the 12th century. The church of Killeshin, in the S.E. of the county, exhibits fine carving of the Norman period. Among the principal old castles are the ruined fortress of the O’Mores occupying the precipitous rock of Dunamase, 3 m. E. of Maryborough, Borris-in-Ossory on the Nore, and Lea Castle on the Barrow, near Portarlington, erected by the Fitzgeralds about 1266, burnt by Edward Bruce in 1315, again rebuilt, and in 1650 laid in ruins by the soldiers of Cromwell.

QUEENSFERRY, a royal and police burgh of Linlithgowshire, Scotland. Pop. (1901) 1850. It is situated on the S. side of the Firth of Forth, 9 m. by road N.W. of Edinburgh and about 1 m. from Dalmeny station on the North British railway, and is sometimes called South Queensferry, to distinguish it from the Queensferry on the opposite shore. Of old it was the ferry giving access to Dunfermline and other places on the north side of the firth, its use in this respect by Margaret, the queen of Malcolm Canmore, originating its name; just as Port Edgar, ¼ m. W., was named after her brother, Edgar Atheling. The Hawes Inn, which figures in Scott’s Antiquary, was the terminus of the run from Edinburgh in the coaching days. Queensferry became a burgh of royalty in 1513, and by warrant in 1589, and belongs to the Stirling district group of parliamentary burghs (with Stirling, Culross, Dunfermline and Inverkeithing). The principal structures include, besides the small parish church of Dalmeny (the best example of pure Norman in Scotland), the Countess of Rosebery Memorial Hall (erected in 1893 by the earl of Rosebery), a library and reading-room, and a public
QUEENSLAND

hall which also does duty as a town hall. A Carmelite friary was converted into an Episcopal chapel in 1890. There is a large oil-works in the parish. Dalmeny House, the seat of the earl of Rosebery, lies in beautifully wooded grounds about 2 m. E. of the ferry. In the park, on the seashore facing Drum Sands, stands Barnbougle Castle, a building of unknown age which became the seat of the Mowbrays in the 12th century. After passing into the hands of the earls of Haddington, it was purchased in 1662 by Sir Archibald Primrose, an ancestor of the earl of Rosebery. The castle was thoroughly restored in 1880. Dundas Castle, 1½ m. S. of Queensferry, was a seat of the Dundases from 1124 to 1875, was besieged in 1449, received a visit from Cromwell in 1651 and was partly rebuilt about 1850. Hopetoun House, nearly 3 m. W. of the ferry, was begun about 1660 from the plans of Sir William Bruce of Kinross and completed by Robert Adam. It is the seat of the marquess of Lintilhgow. Abercorn, a little to the west, gave the title of duke to a branch of the Hamiltons. It was the site of an ancient monastery, and from 681 to 683 the see of the earliest bishopric in Scotland.

QUEENSLAND, a state of the Australian commonwealth, occupying the whole of the north-eastern portion of the Australian continent, and comprising also the islands in Torres Strait. (For map, see AUSTRALIA.) It lies between 10° and 20° S., and is bounded on the N. by Torres Strait and the Gulf of Carpentaria, on the W. by South Australia and the Northern Territory, on the S. by New South Wales and on the E. by the Pacific Ocean. It has an area of 668,497 sq. m., a coast-line of 3000, is 1250 m. long and 950 m. wide at its widest part.

With so extensive a seaboard Queensland is well favoured with ports on the Pacific side. Moreton Bay receives the Brisbane river, on whose banks Brisbane, the capital, stands. Maryborough port is on the Mary, which flows into Wide Bay; Bundaberg, on the Burnett; Gladstone, on Port Curtis; Rockhampton, up the Fitzroy (Keppel Bay); Mackay, on the Pioneer; Bowen, on Port Denison; Townsville, on Cleveland Bay. Cairns and Port Douglas are near Trinity Bay; Cardwell is on Rockingham Bay; Cooktown, on the Endeavour; Thursday Island port, near Cape York; and Normanton and Burketown near the Gulf of Carpentaria. The quiet inner Passage, between the shore and the islands of the group of long Australian-Queensland ports. Brisbane was founded in 1824, but colonization was restricted until 1842, when the Moreton Bay district of New South Wales was thrown open to settlers. It was named “Queensland” on its separation from the mother colony in 1859. A broad plateau, from 2000 to 5000 ft. in height, extends from north to south, at from 20 to 100 m. from the coast, forming the Main Range. The Coast Range is less elevated. A plateau goes westward from the Great Dividing Range, throwing most of its waters northward to the gulf. The Main Range sends numerous but short streams to the Pacific, and a few long ones south-westward, lost in earth or shallow lakes, unless feeding the river Darling. Going northward, the leading rivers, in order, are the Logan, Brisbane, Mary, Burnett, Fitzroy, Burdekin, Herbert, Johnstone and Endeavour. The Fitzroy receives the Mackenzie and Dawson; the Burdekin is supplied by the Cape, Belyando and Suttor. The chief gulf streams are the Mitchell, Flinders, Leichhardt and Albert. The great dry western plains have the Barcoo, Hamarimba, George, Warrego, Maranoa and Condamine. (T. A. C.)

Geology.—Queensland consists geologically of three areas. The eastern division of the state, including all the Cape York Peninsula and the mountainous areas behind the coast, is occupied by the Queensland Highlands, which are built up of a foundation of Archaean and associated Lower Palaeozoic rocks, upon which are superimposed sheets of comparatively horizontal Upper Palaeozoic and Mesozoic rocks. The rocks of the Highlands sink to the west below the Western Plains, which consist in the main of a sheet of Cretaceous clays, capped by isolated ridges and peaks of Desert Sandstone. In the far west the plains end against the foot of an Archean tableland, which is the north-eastern projection of the Western Plateau of Australia.

The oldest rocks in Queensland are gneisses and schists, which appear to underlie the whole of the state. They were originally regarded as metamorphosed Silurian rocks, which had been converted into gneisses, mica-schists and hornblende-schists. Their Silurian age was affirmed owing to their lithological resemblance to rocks in Victoria, which were then regarded as Silurian, but have since been shown to be Archean. The gneisses and schists occupy the Barklay Tableland, the Cloncurry Goldfield and the rocks of the Mackinlay district in the west of the state. The second chief district of Archean rocks is around Laidley, in the Darling Downs, and it includes quartzites, conglomerates and slates, striking from north-west to south-east. The third Archean area occupies the Gilbert, Woolgar and Etheridge Goldfields, and is composed of schists trending from west to east, and with dikes of diorite and granite intruded. South of the Darling Downs the Weather range is on the Clarke Range and on the Peak Downs. To the Archean series doubtless belong some of the many granitic masses, including those of Charters Towers, Ravenswood and Croydon; but some of these granite rocks of Lower Carboniferous age, and some are apparently Moesozoic.

The Lower Palaeozoic sedimentary rocks are widely distributed, but owing to the rarity of fossils they are not well known. In the north-west of Queensland there are some Ordovician rocks, the eastern continuation of those in the Macdonnell Ranges. Silurian limestones occur in the mining field of Chillagoe and at Mount Wyatt. The Upper Palaeozoic systems are well developed, even when compared with those of the same age of the adjoining states. The Coal measures consist of the beds of the Barcoo, the Burdekin and the Condamine, in which are found the Northumberland Archipelago. The Devonian rocks in the Pentland and Gilbert district are estimated to be over 30,000 ft. in thickness; but they probably include some Lower Palaeozoic beds.

The Queensland Carboniferous is divided into five series—the Gympie, Star and the three divisions of the Bowen beds. The lowest series is the Gympie, which occurs between Brisbane and Maryborough. It consists of shales and sandstones, and is covered by marine beds of the same age. The age of these gold-bearing rocks is proved by the presence of such fossils as Productus cora and Prototretopora amplia. The Gympie series is well developed in the districts of Burnett, Broad Sound Bay, Wide Bay, and the hills between Burnett and the south of Cape Palmerston. The Gympie beds are greatly contorted; and those of the Star group are regarded as younger, because they are less disturbed. They are best known in the basins of the Great and Stour rivers. South of these beds are the Bowen beds, which are best developed on the Belyando river and in the Drummond Range, where the shales and sandstones yield abundant fossil fish; on the Star river the shales contain Lepidodendron. The Bowen rock series are divided into the Upper and Lower Bowen series. The Upper Bowen series consists of agglomerates and altered rocks exposed in the Tousaint Range; farther south, the Lower Bowen beds consist of grits, sandstones and shales, which have been altered by some granitic intrusions. The Lower Bowen beds are subdivided into the Lower Bowen, Macdonnell and Glossopteris. The Upper Bowen beds contain coal seams, abundant remains of Glossopteris and one marine band. They form the centre of the basin of the Bowen coalfield; while the Middle Bowen beds contain bauxite. A Lower Oldic coal series also occurs also at Townsville and Cooktown in Northern Queensland.

The rocks of the Mesozoic group may be divided into two divisions, of which the lower includes terrestrial deposits containing coal seams, the upper is mainly a marine formation, but it terminates with a further development of terrestrial deposits. The Lower Mesozoic division includes the Burram and Ipswich series. The Burram series occurs along the eastern coast from Laguna Bay, through the Boyne valley, and in the Macalister and Eidsvold rivers; and it extends inland for about 30 m., where it is faulted against the Gympie beds. The western edge of the Burram beds are described as highly altered in places, by contact with granites. The Ipswich series occupies the north-western corner of Queensland and is the northern continuation of the Upper Clarence series of New South Wales. It contains coal seams which have been worked, though the coal is of inferior value to that of the Carboniferous of New South Wales. One division, the Glenns Creek, near Rockleigh, is 16 ft. thick. Intercalated basals occur in the Ipswich beds, forming the scarps of the Tooowooma Range. The Burram and Ipswich beds have been included in the Trias and the Jurassic, or in both systems as the Trias-Jura, but according to recent authorities the characteristic fossil, Taussopteris daintreei, is of Lower Oldic age.

The Cretaceous system is represented by a lower group of marine clays forming the Rolling Downs formation. They are said to rest conformably upon the Ipswich beds, and some of the fossils found in these beds were first described as Upper Oldic. The affinities of the fauna are in part with Lower Cretaceous and in part with the Cenomanian; so both these series may be represented. The Rolling Downs formation consists in the main of clays, forming the
Impermeable cover over the subterranean stores of water, which maintain the flowing wells of central Australia. The Rolling Downs formation underlies the whole of the Western Plains of Queensland, from the foot of the Queensland Highlands, westward to the Barkly Tableland, and southward to the borders of the south-west and the north, across the state into South Australia and New South Wales. The Desert Sandstone overlies the Rolling Downs formation. Its age is shown to be Upper Cretaceous by the presence of marine fossils, in the formation, and, below in the north, from rocks interbedded in it. In the interior, the Desert Sandstone is entirely of terrestrial and lacustrine origin, and the only fossils are obscure plant remains and some bird bones. Gums and acacias have been cut from Betts Creek, a rock identified as Desert Sandstone, which is said to overlie the Rolling Downs formation; but there is probably some mistake in the stratigraphy, as Gossypium is said to be found in the Rolling Downs formation. If it had survived into the Cretaceous, some specimens of it would doubtless have been obtained from the coal seams of the Lower Mesoic. The Desert Sandstone once covered nearly three-quarters of Queensland, having a wider range than the W. Rolling Downs formation. It was formed partly on land, partly in fresh-water lakes and partly in arms of the sea, as at Croydon and Maryborough. There is no trace of volcanic rocks in this period, and the various surfs of the continent of Queensland are due to the deposition of efflorescent chert. The Desert Sandstone formation has now been weathered into isolated plateaux and tent-shaped hills.

The Cainozoic group includes many volcanic rocks, mainly sheets of basalt, as at Townsville and Hughenden. Near Herberton, between Charters Towers and the Bundoora range, basaltic plateau basalt occupies 2000 sq. m. of country. Their age appears to be Oligocene, as they probably correspond with the oldest Cainozoic basalts of Victoria. Volcanic rocks of a later period occur north of Charters Towers, 'at the foot of the Bundoora hills', in which are recognisable: and a series of hot springs, some of which are described as yeasers, represent the last stage of volcanic activity. The most important Cainozoic sedimentary rocks are the long, narrow brocées, made up of beds of extinct marsupials, such as Diprotodon, Thylacoleo and giant Kangaroos. They appear to have been bogged in the mud by dripping water holes, during droughts. The bones also occur in beds of gravel and sand, and have been found by the Native police, in the deposit. Caves occur in the limestones, and on their floors are there beds yielding bones of marsupials and extinct birds; but no well authenticated case of the ancient remains of man has yet been established.

The chief mineral product of Queensland is gold, found in veins in Archean, Palaeozoic and Lower Mesoic rocks. The most famous gold mining is at Mount Morgan, now changing into a city, Charters Towers and Gympie. Tin is found in the fields of Herberton, Cooktown and Stannary Hills. Copper occurs near Herberton, Chillagoe and Mungana, coal in southern Queensland in the Upper Carboniferous and Permian rocks. The geology of Queensland up to 1892 is given in Jack and Etheridge's Geology of Queensland. The tectonic geology of the coast-line has been described by E. C. Andrews, and the general geology is described in the numerous valuable publications of the Queensland Geological Survey, the geological survey of the Queensland government in 1901. Information regarding the artesian water supply is given in the Annual Reports of the Queensland Hydrological Engineer.

Flora.—The Queensland flora comprehends most of the forms peculiar to Australia, with the addition of about five hundred species belonging to the Indian and Malay regions. There are no mountain ranges of sufficient altitude to make any appreciable change in the plant-life. Bellenden Ker, the highest mountain in tropical Australia, has a height of only 5200 ft., and the plants growing upon its summit, as well as on the lower parts of the coast, seem to be similar to those found on the low lands in the southern parts of the state, and the plants which may be considered as peculiar to these heights are few in number of species. They consist of a Leptospermum and a (Eucalyptus), in which the height of the trees exceeds 100 ft. As these localities is the normal form of Dendrophylia speciosa. These high spots have a few ferns peculiar to them, and of others the only known Australian habitat; for instance, the pretty white flowers of Phyllanthus microcarpus, which is found in Australia been met on the south peak of Bellenden Ker; here also Toeoa Fraseri may be seen with trunks 2 to 3 ft. high. The sides of these mountains are clothed by a dense forest scrub growth, some of the trees of these species higher than the tops of the cliffs. The most attractive of the tall shrubs are Dracophyllum Sayeri, of which there are two forms, Rhododendron Lachae and Orites fragrans, a few orchids of small growth, the number and species known to inhabit these localities is the normal form of Dendrophylia speciosa. These high spots have a few ferns peculiar to them, and of others the only known Australian habitat; for instance, the pretty white flowers of Phyllanthus microcarpus, which is found in Australia been met on the south peak of Bellenden Ker; here also Toeoa Fraseri may be seen with trunks 2 to 3 ft. high. times found to infest the berries. The Queensland Raspberry (Rubus roseus) is widely spread and commonly used, but the fruit is rather insipid. The representatives of the genus Vitis all belong to the sub-genus Cissus; several of them, although somewhat aromatic, are useful for jam and jelly; profuse clusters, the purpose for the purpose is one met with near the Walsh River, V. Gardineri, which is said to bear bunches from 1 lb. to 2 lb. in weight, the berries being large and of pleasant flavour. A large number of nut-like fruits are used by the aborigines. One of the plants of the state popularly known as the fruit of Macadamia ternifolia, the Queensland nut.

The foliage of many plants yields by distillation essential oils, particularly Eucalypts, Backhoisias and other Myrtaceae. As well as some belonging to Rutaceae and Labiatae, especially the genus Monotheca, the Queensland flora contains a profusion of ornamental plants, shrubs, trees and parasites. Of ferns, one-half of the kinds met with in Australia are found in Queensland as well as in the other states, one-fourth in Queensland isolated from the mainland, and thus belong to Queensland. The indigenous ferns equal in number those of New Zealand, and are three times the number of those of Great Britain.

Fauna.—The land fauna of Queensland is essentially one with that of the entire continent. But the geographical position of the state (which exposes it to the plant and animal importations of the intertropical Pacific), has to a notable extent impressed on its fauna characters of its own. It has thus been made the headquarters of Australian bird-life on land and fish-life at sea, the climate being so mild and the waterways being eminently favourable to that wealth of insect and other low types of life which determines the multiplication of the higher. The quadrupeds of Queensland are of the ordinary Australian types and we do not meet with the marsupials, one of the most interesting forms is the Trec-Kangaroo (Dendrolagus), as apart from the habit of climbing trees, which is shared to some extent by the Rock-Wallabies, they afford a peculiar fascination to the sportsman, and to any artist, as it is a storehouse of form and colour. Where flowering and honey-yielding trees prevail, a profusion of birds seek their food either on the insects attracted by the honey, or, if so fitted, on the honey itself; the Rock-Wallabies and the musk-rats, among their mammalian associates, with the forests of eucalypts and acacias, is its richness in honey-eaters and insect destroyers. The former, however, taken as a whole, is not a natural group, but include a family of perching birds and a portion of the parrot family, both furnished with brush girths, intended to be used in defence of the nest. But the most interesting of the Queensland fauna is the splendid development that that quaint company, the bowler birds, among them the regent bird, satin bird, cat birds, &c., constructors of the elaborate playgrounds which have excited so much attention. A third and a prominent feature of the Queensland fauna is its great size and variety, and on its seaboard of three kinds of rile birds, both extensions southwards of the tropical families of cassowaries and paradise birds. In the same region of prolific vegetation the handsome frumenty of the Cassowaries and the large, almost inoffensive, imaginative Dodo and Geese, Swans and Pelicans. It has been said that Australia has no migratory birds: this is an error, founded upon an undue restriction of the term migratory. Several species could be mentioned which are known as migratory birds, such as the Dodo-shrike, Bee-eater, Dollar-bird, &c. On the land surface, among its locally organized products, interest centres in the multitude of varied forms of insect-life, of which the Butterflies and Moths (Lepidoptera), and Beetles (Coleoptera), comparatively little is known at present. Insects of the same kind, flies and mosquitoes, are inconsiderable in number, and possess few hurtful properties. Centipedes, scorpions and leeches are less troublesome than in most other tropical regions. Spiders predominate. The butterflies, like the large spotted Buzzard (Hieroaclea), are exceedingly large, the cinnabar, a small black spider with red spots (Lathrodectus), is malignant. Among the larger insects proper, the great-winged Phasmas, the Skeleton or Stick-insects, the Leaf-insects, and the splendid Swallow-tailed Butterflies (Papilio) are remarkable for size or brilliance of colour.

Fish and Fisheries.—The class fishes is extraordinarily profuse in diversified forms, the coral reefs being the grazing- and hunting-grounds of hosts of gorgeously decorated fish, chiefly of the Wrasse family. One of the most spectable is the Rainbow Trout (Oncorhynchus mykiss), and the volume of the waters is so immense that the catch is proportionate. In shallow waters, especially the fishery in that part of the estuary connected with the sea, the fish are abundant. The macquart, or Macquart's perch (Perca macquartii), is the most abundant species. The brushtail on the west coast is the Peacock Bass (Melanocetus), and the Australian Bass (Perca flavescens) on the east coast. The Eel (Anguilla) is abundant and recent. The Grundy or Dog Whelk (Cerastoderus) is abundant and recent. The Gurnards, Perches, and Pythons are abundant and recent. The Eel is abundant and recent. The Grundy or Dog Whelk (Cerastoderus) is abundant and recent.
barrier reefs are thickets of corals of the most varied forms, in life glowing with colour, in death shrubs of snowy purity. Among the shell-fish conspicuous for beauty or rarity are the exquisitely delicate paper nautilus and Venus comb (Murex tenacissima), the cricket-shells, and other species of the order, all of which require a ship's tackle to lift from its bed. The fishery of the trepang, bêche-de-mer or sea slug employs a considerable number of boats about the coral reefs. Boiled, smoked-dried and packed in grades and sizes, it is marketed in the Orient, where its agreeable and most nourishing soup is relished by Australian invalids. One species of this sea slug—the teat-fish—fetches as much as £240 per ton. The pearl fishery is a prosperous and progressing industry, and the pearl beaches near Torres Strait, from which the traffic is under government supervision. Thursday Island is the chief seat of this industry. The shells are procured by diving, and fetched from £120 to £200 a ton. Mother-of-pearl and tortoise-shell are occasionally obtained. The rock cod, 

**Population.**—The population of Queensland in 1905 was estimated at 528,049—390,206 males and 237,842 females, the density of population per sq. m. being about 0.79. In 1861, that is, two years after the separation from New South Wales, the population of the colony stood at 34,400; in 1871 it had reached 125,100; in 1881, 227,000; in 1891, 410,300, and at the census of 1901, 498,129. The policy of assisted immigration contributed greatly to Queensland's progress, and people of foreign descent are proportionately more numerous than in any of the other states, though they only amount to 8.71% of the total population. At the census of 1901 there were 13,166 Germans, 3,161 Danes, 2,142 Scandinavians, and among coloured aliens 8,587 Chinese, 2,69 Japanese, 939 Hindoos and Cingalees, 937 Pacific Islanders, and 1,787 other races, making a total of 22,900 coloured aliens. It is estimated that the total aboriginal population of Queensland is about 25,000.

The births in 1905 were 13,626, of which 990 were illegitimate, and the deaths 5,033, the respective rates per thousand of the population being 25.92 and 10.47. The decline in the birth rate will be gathered from the following table:

<table>
<thead>
<tr>
<th>Period</th>
<th>Birth Rate per 1000 of Population</th>
</tr>
</thead>
<tbody>
<tr>
<td>1861-65</td>

<tr>
<td>1876-80</td>
<td>36.36</td>
</tr>
<tr>
<td>1881-85</td>
<td>36.37</td>
</tr>
</tbody>
</table>

The death rate shows a remarkable diminution: in 1861–65 it averaged 21.06 per 1000; in 1871–75, 17.94; in 1881–85, 10.10; and in 1891–95, 12.38. The marriage rate in 1905 was 6.04 per 1000, being an increase on the figures for 1904 of 9.

The chief cities and towns, with their population in 1905, are:

- Brisbane, 128,000: Rockhampton, 15,461; Gympie, 13,200; Maryborough, 12,000; Townsville, 10,950; Toowoomba, 10,700; Ipswich, 8,637; Mount Morgan, 8,836; Charters Towers, 6,000; Bundaberg, 5,000.

**Administration.**—As one of the Commonwealth states Queensland returns six senators and nine representatives to the federal parliament. The state parliament consists of a legislative council of 37 members nominated for life, and a legislative assembly of 72 members, who each receive £300 per annum for their services. For purposes of local government the state in 1905 was divided into 46 municipalities and 125 shires. The boroughs control 535 sq. m. and the shires 667,868 sq. m.; the revenue and expenditure of the former in 1905 being respectively £325,510 and £283,645, and of the latter £495,855 and £180,457. Revenue is mainly derived from land taxes and on the capital value of assessed properties, which amounted for the whole state to £42,358,173, representing an annual value of £2,957,400. All improvements are exempt from assessment, and much of the revenue is expended in road-making and the building of bridges. Rates are supplemented by an endowment from the central government.

**Education.**—Public education is free, sectarian and compulsory. State or provincial schools are formed whenever an average attendance of twelve children can be got. Theoretically the school is engaged to teach every child, in practice compulsory attendance is seldom if ever enforced in certain parts, owing mainly to the difficulty of providing suitable schools within reasonable access. In 1905 there were 1,944 state schools, with 238 teachers and 508,800 children, or an average attendance of 171. In the total number of denominational schools, there were 113, with 739 teachers and 14,891 pupils. Exclusive of coloured aliens almost the whole adult population can read and write. In 1905 the sum spent on education was £59,755. Ten grammar schools are endowed by the government to assist in providing the government gives free education in grammar schools to scholars in state schools, and also three-yearly exhibitions to students who pass an examination of a high standard. State aid is also offered to schools of art, schools of design, free libraries and technical schools.
QUEENSLAND

There is no state church. Amongst the different denominations the Church of England, at the date of the last census, numbered 37.5% of the population, the Roman Catholic 24.5%, the Presbyterians 11.7, the Methodists 9.7, the Baptists 2.56, the Pioneers 2, other Christian bodies 12.3, Pagans and Mahomedans, 4.43.

Finance.—For the year ending June 1905, the receipts amounted to £5,955,399, equal to £6, 175, 101.9 per inhabitant. The chief items were as follows:—interest on public debt £5,457,415; railways, £1,409,414; balance refunded by the federal government, £752,532. The expenditure for the year was £3,581,403, equal to £6, 175.4. per inhabitant; the chief items being:—interest on public debt £2,457,415; railways £1,409,414; the chief charitable institutions, £355,338. The public debt of the state at the end of 1905 was £39,906,827, or 74.6. 8d. per inhabitant; the bulk of this sum, £25,567,534, having been expended on railways.

The following shows the growth of the public indebtedness:

Defence.—The Commonwealth defence forces in Queensland had an actual strength at the end of 1905 of 7,712 men, comprising a permanent force of 2,665 militia, 959 cadets and 3,115 rifles.

Mining.—In Mount Morgan Queensland possesses one of the chief gold-producing areas of the world, and that with a copper-mining industry which is closely linked with it. The estimated production of copper in 1905 was 958,100 lb. At the end of 1905 the market value of copper was £2,709,951, while the value of the output stood at £8,130,480.

Commerce.—The shipping entering Queensland ports in 1905 had a value of £4,077,741, as compared with £6,626,000 in 1904. The imports in 1905 were £5,698,345, which is much less than the average of Australia, but nearly all the Queensland imports are for home consumption, whereas New South Wales, Victoria and South Australia import large quantities for re-export. The total value of plant and machinery was £2,988,056; and of land and premises £2,709,951. The exports from Queensland in 1905 were valued at £11,939,594, which is equal to the very high average of £22, 14s. 3d. per head; nearly the whole amount represents goods and produce of local origin. Going back to 1881 the amount of exports at the various decennial periods was:

Brisbane is the chief seat of trade, but this port does not hold so predominant a position as do the chief cities of the other states in regard to their minor ports. In 1905 the trade at the seven principal seaports of Queensland was:

<table>

Railways.—Up to 1905 the state had expended £2,683,355 upon the construction and equipment of railways. The mileage open for traffic at the end of that year was 3,131; there were also 268 m. of privately-owned road per mile. Of population that was connected with the railways in 1863, some five years after the introduction of responsible government. Progress during the early years was very slow; in 1867 only 218 m. had been constructed and in 1881 only 2,005,876 m. During the last ten years construction was pushed forward rapidly, and an average of 152 m. a year being opened between those dates. In 1891 the length open for traffic was 2,320 m., and in 1891 2,801 m. The state railways in 1905 earned £1,453,355 and the expenditure was £551,627, leaving the net earnings £891,728, which is equal to 2.91% upon the capital expended. As the rate of interest paid on the outstanding loans of the Queensland government is 3%, there is an actual loss to the state of 0.9%. The chief sources of revenue were custom duties, the excise duties, and the profits resulting from the construction of the railways.

Posts and Telegraphs.—There were 1,360 post offices in the state in 1905; telegraph stations numbered 155, and there were 19 telegraph exchanges. The revenue from post and telegraph stations in 1905 was £323,523, £88,285 and £31,276—a total of £453,355, as against an expenditure of £45,420.

Banking.—The liabilities of the eleven banks trading in the state in 1905 totalled £36,580,000, of which deposits amounted to £31,217,084. The banks held coin and bullion to the value of £1,897,756. In the Government Savings Bank there was a sum of £3,692,756 to the credit of 8,416 depositors. The deposits in all banks amounted, therefore, to £17,209,842, which represented 6.2% of the value of the total assessment of £277,961,670.

Queensland

History

The Portuguese may have known the northern shore nearly a century before Torres, in 1605, sailed through the strait since called after him, or before the Dutch landed in the Gulf of Carpentaria. Captain Cook passed along the eastern coast in 1770, taking possession of the country as New South Wales. Flinders visited Moreton Bay in 1802. Oxley was on the Brisbane in 1823, and Allan Cunningham on Darling Downs in 1827. Sir T. L. Mitchell in 1846-47 made known the Maranoa, Warrego, and Barcoo districts. Leichhardt in 1845-47 traversed the coast country, going round the gulf to Port Essington, but was lost in his third great journey. Kennedy followed down the Barcoo, but was killed by the blacks while exploring York Peninsula. Burke and Wills crossed western Queensland in 1860. Leichhardt, Walker, M'Kinlay, Hann, Jack, Hodgkinson and Favence continued the researches. Squatters and miners opened new regions. Before its separation in 1859 the country was known as the Moreton Bay district of New South Wales. A desire to form fresh penal depots led to the discovery of Brisbane river in December 1823, and the proclamation of a penal settlement there in August 1826. The convict population was gradually withdrawn again to Sydney, and in 1842 the place was declared open to free persons only. The first land sale in Brisbane was on August 9, 1843. An attempt was made in 1846, under the colonial ministry of Gladstone, to establish at Gladstone on Port Curtis the colony of North Australia for ticket-of-leave men from Britain and Van Diemen's Land. Earl Grey, when secretary for the Colonies, under strong colonial appeals arrested this policy, and broke up the convict settlement. In 1841 there were 176 males and 24 females; in 1844, 540 in all; in 1846, 1867. In 1834 the governor and the English rulers thought it necessary to abandon Moreton Bay altogether, but the order was withheld. The first stock belonged wholly to the colonial Government, but flocks and herds of settlers came on the Darling Downs in 1841. In 1844 there were 17 squatting stations round Moreton Bay and 26 in Darling Downs, having 13,295 cattle and 181,051 sheep. In 1849 there were 2812 horses, 72,006 cattle, and 1,077,983 sheep. But there were few persons in Brisbane and Ipswich. The Rev. Dr Lang then began his agitation in England on behalf of this northern district.

Some settlers, who sought a separation from New South Wales, offered to accept British convicts if the ministry granted independence, and promised to their memorial, ticket-of-leave men were sent in 1830. In spite of the objection of Sydney, the Moreton Bay district was separated from New South Wales by an Order in Council of 13th May 1859, and proclaimed the colony of Queensland. The population was then about 20,000, and the revenue £6475.

The constitution, which was based on the New South Wales Act of 1853, provided for 16 electoral districts, with a representation of 26 members. A Legislative Council was also formed, to which the governor of New South Wales, Sir William Denison, appointed 5 members, to hold office for four years, and Sir George Ferguson Bowen, the first governor of the new colony, 8 life members. Robert (afterwards Sir Robert) George Wyndham Herbert was the first premier and colonial secretary; and held office until 1856. Of the 39 representatives in the first Parliament, 20 were pastoralists; the others may be roughly classed as barristers, solicitors, and merchants. The pastoralists were the pioneers of settlement in the colony; those best known were the Archers of Gracemere, the Bells of Jimboor, the Gores of Yandilla, the Bigges of Mount Brisbane, Mr (afterwards Sir) Arthur Hodgson, Robert Ramsay, Gordon Sandeman, and Messrs Kent and Wienhold. The white population at the end of 1859 was 25,788, and the exports were valued at £500,000.

Herbert's Administration, 1859-1860.—The first Parliament was opened on May 29, 1860. The providing of revenue and the establishment of immigration were the chief matters for consideration. The treasury was practically empty, but Sir Saul Samuel, treasurer of New South Wales, took a broad and generous view of the situation, and rendered financial aid, whilst in 1861 the first Government loan of £123,800 was authorized, the money being appropriated to public works and European immigration. Labour was so scarce that as early as 1851 the squatters had imported Chinese; various schemes for the introduction of coolies on a large scale were now mooted, but public opinion was decidedly against any increase in the number of coloured aliens then in the colony. In 1859 the educational system was a mixed national and denominational one; there were 10 schools of the latter class, 1 of the former, and 30 private schools. In 1860 a Board of General Education was established, which extinguished the denominational system and placed the schools under State control. In the same year Stannard's Act to religion was abolished. The governor, in opening Parliament in 1859, pronounced decidedly against the reintroduction of convicts. In that year Queensland boldly grappled with the extension of colonizing, and a settlement was established at the northerly point of Cape York peninsula by Mr Jardine. During the following two years ports were opened along the coast, and pastoral occupation spread far into the northern and western interiors. The first sod of the first railway, from Ipswich to the Darling Downs, was turned on 15th February 1864. On February 1, 1866, Mr Herbert retired, and Mr Macalister became premier and Mr Mackenzie colonial secretary. In the following July the failure of the Overend and Gurney and Agra banks, in the latter of which the Government had public moneys, caused the collapse of a loan which was being negotiated in London. A panic followed: the Government could not pay the railway contractors, and the navies employed by them started for Brisbane, threatening to hang the ministers and loot the town. On arrival, however, they were easily headed off to a reserve. By this time the treasury was empty, general insolvency prevailed, and the community appeared to be wrecked. Treasury bills to the amount of £300,000 were issued, and the governor in council was authorized to legalize treasury notes, when necessary, as currency, payable in gold on demand, to tide over the crisis. Prior to this, however, the treasurer took preliminary steps to issue £300,000 "Legal Tender Notes"—inconvertible "greenbacks"—but Sir George Bowen informed the premier that he should veto such a scheme, and suggested the issue of treasury bills. Mr Macalister thereupon resigned, and Mr Herbert, who had made arrangements to proceed to England where he became permanent secretary of the Colonial Office, took office again to help his way through the difficulty. His second ministry lasted for eighteen days, and, having passed the Treasury Bills Act, he retired from the public life of Queensland. The only determined opposition the Herbert ministry met with was from the townspeople's representatives, whose contention was that the squatters dipped too deeply into the public purse for public works expenditure; but an important factor in the early parliamentary days was the opposition between the Brisbane and Ipswich parties in the House, the latter town aspiring to be the capital of the colony.

The Discovery of the Goldfields, 1866-1879.—Macalister returned to power in August 1866, and dealt so vigorously with the after-effects of the financial crisis that by the end of 1867 affairs had approached their normal condition. A new era was now opened for Queensland by the discovery of gold. The Gypie field was discovered by Nash in 1867, and a big "rush" resulted. In 1872 Hugh Mosman discovered Charters Towers, the premier goldfield of the colony; and Hann, the rich Palmer diggings. Other important discoveries were also made, and Queensland has ever since been a gold-producing colony. Mining is the foundation upon which much of the progress of the colony has been built, and the legislation and records show continuous traces of the influence of the gold-getter. In 1873 John Murtagh Macrossan, a digger, was returned to Parliament expressly as a mining representative; and other men of a different stamp from the representatives of the squatters and townspeople, who had
hitherto composed the House, now began to enter public life.
From 1879 to 1879 progress was satisfactory, trade interests
were prosperous, and in this decade the foundations of the
public and social structure of Queensland were laid. Agriculture
was extended, and sugar-growing took the place of cotton
cultivation. (The first crop of sugar was grown by the Hon.
Louis Hope at Cleveland, about 1862.) Hitherto politics had
been non-partisan, and legislation was chiefly of a domestic
character. From the time of Herbert’s departure until the
appearance of Thomas McIlwraith and Samuel Walker Griffith,
the two master-spirits of Queensland parliamentary life, the
political history of the colony was composed of short-lived
administrations, with Messrs Macalister, Mackenzie, Palmer,
Lilley, George Thorn and John Douglas (afterwards Governor
Resident at Thursday Island) as premiers. Arthur Hunter
Palmer (whose administration, from 1870 to 1874, had the
longest life), a New South Wales squatter, entered the Queens-
land Parliament in 1886. He was one of the most popular of
Queensland’s parliamentary leaders, and has left the impress
of his labours on the public works, and educational and defence
forces systems of the colony. In 1870 Queensland was dis-
appointed in her ambition of becoming the connecting-point
for Australia with the European and Eastern cable systems.
A company—the British Australian Telegraph Company—was
formed in London to connect Australia by cable with Singapore.
The plan provided for a land line from the Queensland telegraphs
at Burketown to Port Darwin, in the Northern Territory, where
the cable was to be landed. Writing on 25th January 1870,
the Telegraph Construction and Maintenance Company officially
informed the governor of Queensland that it had received a
contract from the British Australian Telegraph Company to
construct “cables and land lines, to be laid between Singapore
and Burketown, in North Australia.” The Construction
Company deputed Commander Osborn to negotiate with the
Governments of South Australia and Queensland in reference
to the land line; but on arrival in Adelaide he accepted the offer
of the South Australian Government to construct and maintain
a telegraph line right across the continent from Port Darwin to
Adelaide, and Queensland was informed that the original plan
had been abandoned. Although the company was thus saved
the expense of making and maintaining the Port Darwin–Burke-
town line, it was regarded as having broken faith with Queens-
land, which had specially pushed on her telegraph system to
connect with the proposed line. In consequence of this incident
Queenslanders have not always had the facilities for cheap cabling
to Europe enjoyed by the other colonies, though the subsequent
owners of the cable, the Eastern Companies, were in no way
responsible for the act of their predecessors.

A resolution in favour of the payment of members was
carried in 1871. In 1872 the first Agent-General in London,
Richard Daintree, was appointed. The same year the Railways
Act Amendment Act was passed, authorizing the construction
of railways by private enterprise, land being offered as com-
pensation to companies for the lines; the amount of compensation
was increased to forty-two members. In January 1874 Palmer resigned,
and Macalister came into power for two years, the most im-
portant measure of his Government being the State Education
Act of 1875, on which the present educational system is based.
Both Messrs McIlwraith and Griffith were members of the
Macalister ministry, but the former resigned in October 1874,
owing to a difference of opinion as to a proposed land-grant
railway from Dalby to Normanton. In 1878 Mr (afterwards
Sir) James Francis Garrick first became a cabinet minister,
joining the Douglas ministry as secretary for public works and
mines.

Active Politics, 1879-1890.—On 21st January 1879 the first
McIlwraith administration came into power, and an import-
ant extension of local government was one of the early measures
passed, divisional boards being formed to take charge of public
works in districts not included in municipalities. In the
following session, 1880, the Opposition, led by Mr Griffith,
bitterly opposed the Government proposals on Kangara labour,
land-grant railways, and a European mail service via Torres
Straits. The Government, however, concluded an agreement
with the British India Steam Navigation Company for a monthly
mail service between Brisbane and London for an annual
subsidy of £55,000. The Railway Companies Preliminary Act,
giving the governor in council power to treat with persons
willing to construct railways in return for grants of 8000 acres
of land for each mile of rail laid, was also passed. This measure
was generally unpopular, and no railways were built under its
provisions. During the session Mr Griffith impeached the
premier in connexion with contracts for the purchase of 15,000
tons of steel railway metals, and their carriage to the colony,
made in London whilst McIlwraith was there in January 1880.
A select committee in the colony, and afterwards a Royal
Commission in London, subsequently reported in the premier’s
favour. The discovery of the celebrated Mount Morgan gold
mine, and the initiation of artesian well-boring by R. L. Jack,
Government geologist, took place in 1881. In 1883 a great
drought prevailed, and the compulsory stoppage of public works
demoralized the labour market. Early in the year information
reached the colony that Germany proposed to annex a portion
of New Guinea, which, together with other islands in the Papanap
Gulf, was becoming of great strategic value to Australia; and
the premier, fearing that it would thus be lost to the empire,
-instructed Mr H. M. Chester, police magistrate at Thursday
Island, to proceed to Port Moresby and take possession of the
unappropriated portion of the island in the name of the crown.
This act was afterwards—to the indignation of Australia—repudiated
by Lord Derby; and, eventually, under the Berlin
Treaty of 1886, England and Germany entered into joint-
-possession of that part of New Guinea lying east of 141° E. In
July Sir Thomas McIlwraith (created K.C.M.G. in 1882) was
defeated by 27 votes to 16 on a proposal to arrange for the
construction of a land-grant railway from Charleville to the
Gulf of Carpentaria. The general elections which followed were
fought mainly on the questions of coloured labour for the sugar
plantations and land-grant railways. The Government was
defeated, and Griffith formed his first administration. Later
in the year the premier drafted the Federal Council Act at
Sydney, and through his efforts Queensland eventually joined
the Federal Council of Australasia. In 1884 a ten-million Loan
Act was passed, intended to secure continuity in borrowing for
railway construction, but many of the lines specified were
unsurveyed. According to the view now generally held in
Queensland, this loan seriously hampered the colony in after
years. In 1887 the number of seats in the Assembly was
increased to 72 (the present number), and several reforms were
effected in the public service, notably the establishment of the
department of agriculture. At the general elections in 1888
Sir Thomas McIlwraith was returned for North Brisbane, defeating
Sir Samuel Griffith (who had been created K.C.M.G. in 1886)
by a large majority, and resumed office as premier and leader of
the “National Party.” Ill-health, however, soon compelled
him to resign, and in 1889 he was succeeded by Boyd Dunlop
Morehead. Sir Thomas McIlwraith’s inflexible nature was
evidenced all through his public life. On the death of Sir
Anthony Musgrave in Brisbane in 1888, he maintained that the
Government should be consulted as to the appointment of the
new governor. Lord Knutsford declined to accept this view,
and appointed Sir Henry Blake. The premier formally protested,
and a deadlock ensued, which was only removed by the resigna-
tion of the governor-designate. In 1889 payment of members at
the rate of £300 a year, plus 1s. 6d. per mile travelling expenses,
was established. In 1890 a financial crisis arose. Sir Thomas
McIlwraith had returned to the colony and dissociated himself
from the ministry. He conferred on the situation with Sir
Samuel Griffith, and a want-of-confidence motion was nearly
-carried. Morehead resigned, and a coalition ministry, with
Griffith as premier, chief secretary and attorney-general, and
McIlwraith as treasurer, was formed. An agitation for the
separation of Queensland into two or three separate colonies—
mentioned as early as 1886—was very marked during this

Queensland
period. It took formidable shape at Townsville in 1882, the chief argument in its favour being that the north and central districts did not get a fair share of the public expenditure. Delegates were sent to London on several occasions to interview the Colonial Secretary, but success did not attend these direct appeals. Sir Samuel Griffith’s Decentralization Bill of 1890, which proposed to erect separate legislatures in the three divisions with powers of local government, was a blow to separationists, and the agitation gradually disappeared.

The Labour Party in Politics, 1890-1900.—The decade from 1890 to 1899 was chiefly notable, apart from the accomplishment of Federation, for the rise of the Labour party as a power in politics and the gradual disappearance of the squatter as a dominant factor. In 1890 the old opponents, Sir Samuel Griffith and Sir Thomas McIlwraith, were still working side by side. The revenue for the year fell short of the estimates by half a million sterling, and a heavy accumulated deficit had to be grappled with by Parliament. Sir Thomas McIlwraith, the treasurer, proposed a dividend tax and other imposts, which were agreed to, and a Treasury Bills Act authorizing an issue of £2,500,000 was also passed. A Constitution Act establishing triennial Parliaments, in place of quinquennial, which had hitherto existed, also went through. In August the great maritime strike spread to Brisbane, and crippled trade and commerce for several months. In 1891 a loan for £2,500,000, which was issued in London under the auspices of the Bank of England, failed. Sir Thomas McIlwraith reflected strongly in Parliament on the conduct of the Bank of England, and the governor of the bank wrote to Sir James Garrick, the agent-general, protesting against Sir Thomas McIlwraith’s statements, and breaking off relations with the colony; but mutual explanations afterwards healed the breach.

Litigation was initiated by the London board of the Queensland Investment and Land Mortgage Company against the Queensland directors, on the ground that they had made advances without taking adequate security. The case was tried by the chief justice, Sir Charles Lilley, in 1891 and 1892, the defendants being Sir Thomas McIlwraith, Sir Arthur Palmer, then president of the Legislative Council, and Messrs F. H. Hart and E. R. Drury. The judge submitted 143 questions to the jury, and though these were answered generally in favour of the defendants, judgment was entered largely for the plaintiffs. On appeal, heard before a specially constituted court, presided over by the late Sir William Windeyer of New South Wales, this judgment was reversed, with costs. Lack of employment and a disastrous strike of bush workers paralysed the colony in this year. The strike began in January at Logan Downs station, where 200 shepherds refused to sign the Pastoralists’ Convention agreement. This strike was remarkable for the determined and aggressive attitude of the men, and the firm, though conciliatory, manner in which their cases were handled by Mr (afterwards Sir) Horace Tozer, the colonial secretary, who had to provide military forces and artillery to hold the strikers in check. The trouble lasted many months; and after it was over a farrically planned plot to seize the central district and proclaim a republic was revealed in the Brisbane Courier. As an outcome of this strike, “New Australia”—a settlement on communistic lines—was founded in Paraguay (q.v.). The year 1892 was one of gloom and depression: want of money interfered with public works, and the impending stoppage of Kanaka labour and the low price of sugar almost ruined the planters. Sir Samuel Griffith then announced his conversion to the policy of continuing Kanaka labour for the sugar plantations, and also of land-grant railways.

An act was passed authorizing agreements with companies for the extension of the trunk lines on this principle; but the measures were unpopular, and no transactions under the act are recorded. Financial depression reached its height in 1893: the salaries of ministers and civil servants were reduced, and drastic retrenchments were made in every department. In February, 107 in. of rain fell at the head of the Brisbane river, and enormous losses were caused by the resulting floods; several vessels, including the Queensland Government gunboat Paluma, were washed into the Brisbane Botanic Gardens, and left high and dry when the waters subsided. A second flood followed and caused further losses. Rockhampton, Bowen, Townsville, and other places also suffered severely from floods. On 13th March Sir Samuel Griffith was gazetted chief justice, and on the 27th Mr (afterwards Sir) Hugh M. Nelson became premier and treasurer, and Sir Thomas McIlwraith chief secretary and secretary for railways. Parliament was dissolved on 3rd April, and after the general elections the ministry returned with 38 supporters, against Labour, 16, and Opposition and Independent, 18. During the month several financial institutions suspended payment, and on 15th May the Queensland National Bank closed its doors. Parliament was hurriedly summoned to deal with the financial crisis and the question of the Government funds held by the Queensland National Bank. Treasury notes, issued against coin held by the treasurer, were made legal tender throughout the colony; an issue of £1,000,000 treasury bills to retire the treasury notes was authorized, and a series of acts dealing with the suspended banks were passed. To assist the unemployed, labour and co-operative communities were started, but proved failures. An impetus was given to the sugar industry by the Sugar Works Guarantee Act, which authorized the treasurer to guarantee debentures issued by companies for the erection of sugar mills and plant. In 1894 little legislation was achieved, the policy of the Government being directed towards national rehabilitation. In 1893 Sir Thomas McIlwraith left the colony for London, where he died on 17th July 1900. At the general election of 1896 the Labour party slightly improved its position. In that year a committee of investigation reported a heavy deficit in the affairs of the Queensland National Bank, and made certain recommendations. In 1897 Queen Victoria issued a Royal Despatch, forming the foundation of a new relationship between the Colonies and the Crown, which was intended to prove favourable to the institution. An act was passed granting powers to a company to construct a railway from the rich mining district of Chillagoe to the terminus of the Cairns railway at Mareeba; at the end of fifty years the State was to have the right to acquire the line. In April 1898 the Queensland-born statesman, T. J. Byrnes, whose early death in the following September was lamented throughout Australia, succeeded Sir Hugh Nelson as premier. On 24th October the trial of the three ex-directors of the Queensland National Bank, Messrs F. H. Hart, B. D. Morehead and A. B. Webster, was commenced. The prosecution was instituted by the Government, on the advice of three barristers to whom the report of the committee of investigation into the affairs of the bank, which sat in 1897, was submitted. After a trial lasting 12 days, a verdict of “Not guilty” was returned. Proposals for the acquisition of 250,000 acres of land in New Guinea, made by a syndicate of London capitalists, were provisionally agreed to, but were eventually rejected, owing to a popular outcry raised in the colony and in New South Wales and Victoria. In 1896 the first of a series of factory acts was passed, and in 1907 Wages Boards were established for fixing the statutory minimum rate of wages. (See Australia.)

Federation was a burning question in the neighbouring colonies during the year, but Queenslanders generally took little interest in the movement, and the colony was not represented at the Federal Convention at Melbourne when the Commonwealth Bill was passed. In 1899 Mr (afterwards Sir J. R.) Dickson, who had succeeded Byrnes as premier, was enlisted on the side of the “Billies,” and in June of that year an Enabling Bill was passed. In September the Referendum supported the act by the narrow majority of 7412 votes on a poll of 69,434. Towards the end of the second session the ministry was thrown out on the failure of the Railway Transport Board, and Committees Bill, and resigned. Mr Dawson, leader of the Labour Opposition, then formed a ministry, and held office from 1st December to 7th December 1899. He was then defeated on a motion by R. Philip, and resigned, and Philip
QUEENSTOWN

became premier, and was in power when Queensland joined the Commonwealth. The year was shadowed by the continuance of a terrible drought, which towards the end of 1900 became so aggravated that the revenue began to fall off, owing to decreased receipts from railways and land. In that year Philip’s chief policy was the passing of legislation to permit the construction of railways by private enterprise. The Labour party offered vigorous opposition; but notwithstanding this a certain amount of progress was made. The Government appointed Dr Maxwell, an American sugar expert, to superintend the sugar industry in the colony; a State school of mines was established at Charters Towers; and the compulsory clauses of the Education Act were put in force for the first time. Another act of importance was the establishment of a Government land bank. A powerful agitation for the extension or renewal of the leases of pastoral lands was raised, but no legislation resulted. A suggestion that Sir Samuel Griffith should retire from the chief justiceship, on a pension of £1,750 a year (to be reduced by any amount received), to enable him to enter Federal politics, fell through. Some important discoveries of coal were made during the year, and dredging the northern rivers for gold became an established industry. J. R. Dickson represented the colony in London at the conference of Federal delegates in 1900, when the final details of the Commonwealth were settled. Early in 1901 he was created K.C.M.G., but died somewhat suddenly, at Sydney, on 9th January of that year, shortly after he had been made a member of the first Federal ministry.

Alien Immigration.—The working classes of Queensland have always objected to the presence of coloured aliens, and successive Governments have legislated against indiscriminate immigration into the colony. In 1876 Governor Cairns reserved an act imposing certain duties on Chinese immigrants; and in 1887 a poll tax of £10 was imposed upon Chinese arriving. In 1884 another principle was adopted: masters of ships were only allowed to carry to Queensland ports one Chinese for every 50 registered tons of their vessels, and a poll tax was increased to £25. In 1897 the act was amended to provide for the return of all Chinese immigrants, the outcome of which was the adoption of uniform legislation: in the Queensland Act passed that year the main provision was that only one Chinese could register with every 500 registered tons of shipping. The poll tax was then abolished. This act was also reserved, but received the Royal Assent on 5th February 1890, after slight modification had been made.

Tens of thousands of Japan had been carried through by the Imperial Government, at the initiative of the Queensland, under which the Japanese Government undertook to prevent the emigration of coolies to the colony; and a Pearl Shell Fisheries Act was passed to prevent the destruction of the aboriginal coquinas. The act of 1884 and the Act of 1897—the Agricultural Lands Purchase Acts—under which the State was authorized to purchase suitable estates of specially fertile land already alienated, to be cut up and thrown open as agricultural land, contained provisions to encourage agriculture. Owing to the expiration of pastoral leases and the fact that no legislation existed for their renewal for a term long enough to encourage the investment of capital, a formidable law was arrived at, produced by the creation of agricultural homesteads, and the leasehold system, at £10, 50 or 60 acres, grazing homesteads (20,000 acres), scrub selections (10,000 acres), and unconditional selections (240 acres). Some of this classes of selections could be purchased right out, and the leasehold tenure at extremely moderate rates. Sales of country lands were established in 1884, 1885, 1886, 1887, 1888, 1889, and 1890—1897—the Agricultural Lands Purchase Acts—under which the State was authorized to purchase suitable estates of specially fertile land already alienated, to be cut up and thrown open as agricultural land, contained provisions to encourage agriculture. Owing to the expiration of pastoral leases and the fact that no legislation existed for their renewal for a term long enough to encourage the investment of capital, a formidable law was arrived at, produced by the creation of agricultural homesteads, and the leasehold system, at £10, 50 or 60 acres, grazing homesteads (20,000 acres), scrub selections (10,000 acres), and unconditional selections (240 acres). Some of this classes of selections could be purchased right out, and the leasehold tenure at extremely moderate rates. Sales of country lands were established in 1884, 1885, 1886, 1887, 1888, 1889, and 1890—

The Act of 1897 it forms the basis of the existing land regulations of Queensland. Under the 1897 act the passing of the land into the hands of agriculturists marked a new era. It was enjoined by the Government to encourage agriculture. Owing to the expiration of pastoral leases and the fact that no legislation existed for their renewal for a term long enough to encourage the investment of capital, a formidable law was arrived at, produced by the creation of agricultural homesteads, and the leasehold system, at £10, 50 or 60 acres, grazing homesteads (20,000 acres), scrub selections (10,000 acres), and unconditional selections (240 acres). Some of this classes of selections could be purchased right out, and the leasehold tenure at extremely moderate rates. Sales of country lands were established in 1884, 1885, 1886, 1887, 1888, 1889, and 1890—

QUEENSTOWN, a town of the Cape province, South Africa, in the upper valley of the Great Kei river, 155 m. by rail N.W. of East London. Pop. (1904) 9616, of whom 4157 were white. Founded in 1853 and named after Queen Victoria, it was laid out in an unusual form. From each angle of a central hexagonal-shaped open space there runs one of the main thoroughfares. This arrangement was adopted to facilitate defence in case of an attack by Kaffirs. Queenstown is the site of its formation. Up to 1868 the burghers held their lands on a military tenure. It contains several fine buildings, including the town hall, court-house and public offices and the Anglican church of St Michael. Many of the streets are lined with oaks and blue gums. Situated on the Karoo, at an elevation of 3500 ft., between the Stormberg and Amatola Mountains, it is the centre of a wheat and sheep-rearing district, and is a busy commercial town. The climate is healthy, and Queenstown has a reputation as a sanatorium.

QUEENSTOWN, a town of Montagu county, Tasmania, on the Queen river, 23 m. by rail by Strahan, and 353 m. w. of Hobart. It is the centre of the Mount Lyell mining district and has numerous smelting works, brick-works, and sawmills. The county is mountainous and finely wooded. Pop. (1901) 5931 of the district, 10445.

QUEENSTOWN (formerly Cove of Cork), a seaport, watering-place, and naval station of county Cork, Ireland, picturesquely situated on the south side of Great Island, on the slope of an
eminence rising abruptly above Cork Harbour. Pop. (1901) 7909. It is 12 m. E.S.E. of Cork and 177 m. S.W. of Dublin by the Great Southern & Western railway. It consists chiefly of terraces rising one above another with wide streets and handsome houses. On account of the mildness of the climate it is frequented by visitors both in summer and winter. Previous to the American War, Cove of Cork was a small fishing village, but it subsequently increased rapidly. It received its present name on the occasion of the visit in 1849 of Queen Victoria, being her first landing-place in Ireland. The town is governed by an urban district council. The harbour, which is defended by the Carlisle and Camden Forts at its entrance, and by Fort Westmoreland on Spike Island, can shelter a large fleet. Spike, Rocky and Haulbowline islands are used in the formation of a government dockyard, which with the adjoining victualling yard covers an area of 53 acres. There is an enclosed basin 9 acres in extent, with 32 ft. 8 in. depth over the sill at high-water spring tides; and a dry dock at its southern end has a length of 460 ft. on the blocks. Queenstown is a port of call for American mail steamers, and the mails are transmitted overland by express trains; it is also a port of embarkation for colonial troops, and a government emigration station. The admiral’s flagship is stationed here. The oldest yacht club in the United Kingdom, the Royal Cork (founded in 1720 as the Cork Harbour Water Club), has its headquarters here, with a club-house, and holds an annual regatta. Among the principal buildings are the modern Catholic cathedral of St Colman for the diocese of Cloyne, designed by A. W. Pugin, and the Protestant Episcopal church for the united parishes of Clonmel and Temple Robin. A fine promenade, over a mile in length, connects Queenstown with Rushbrook, a favourite waterling-place. The picturesque shores of the harbour are dotted with country residences and village-resorts, such as Crosshaven and Church Bay.

QUELPART (Chai-Jo), an island to the south of Korea, used as an island penal settlement. In measures 40 m. from E. to W. and 17 from N. to S. It rises gradually from the seaboard, is heavily wooded and is cleared for cultivation to a height of 2000 ft. There are several crateriform hills, and Hali San (Mount Auckland) has an altitude of 6528 ft. The island is entirely volcanic, and the soil is finely disintegrated lava. Broken black lava forms the beach, and blocks of it are the universal building material. There is no good drinking water. The flora and fauna are scarcely investigated. Pines of three species, junipers, larches, oaks, maples, willows and the Thuya Orientalis have been identified. The known fauna comprise boars, bears, deer, swans, geese, pheasants and quail. The roads are scarcely passable bridle tracks. Quelpart was introduced to European notice by the Dutchman, Hendrik Hamil, who was shipwrecked there in 1653.

The estimated population is 100,000, Korean by race, language and costume. There are about ninety villages. The valleys and spaces in the hills are divided by stone walls, and produce beans, peas, sweet potatoes, "Russian turnip radish," barley, a little rice and millet, the last being the staple article of diet. Nuts, oranges, limes and plums are grown. Small but strong ponies are bred for export, and small cattle and pigs for home use. Apart from agriculture, the industries consist in the manufacture of fine bamboo hats and mats, and wooden combs for export and local use. For fishing the islanders use double-decked raft boats, similar to those of southern Formosa. Their lucrative pearl fisheries have been practically monopolized by the Japanese, who use proper diving apparatus. A valuable product is a species of clam, the shell of which furnishes a specially iridescent mother-of-pearl, which the natives barter with the Japanese for inlaying lacquer. European goods are not imported, but Japanese articles find ready barter. There are no markets, and only a few poor shops.

Chu-sung, the capital and seat of government, a few miles from Port Pelto, has a black lava wall 25 ft. high, with three gates and towers; an imposing audience-hall in Chinese style; and a great bell tower, with a fine bronze bell, sounded to drive off “evil dragons.” Its population is estimated at 16,000. The governor has a hereditary army for coercive purposes. The uniform is a complete suit of mail, with a helmet, from which leather curtains fall over the shoulders. The weapons are equally antique.

There are no good harbours, and the only anchorage for large vessels is Tai-chung, or Yung-su, at the east end, with 9 to 13 fathoms of water. Pelto has ancient breakwaters for the protection of small boats, erected, as many believe, by the Mongol conqueror, Kublai Khan, who in 1273 built on Quelpart one hundred ships for the invasion of Japan.

QUENSTEDT, FRIEDRICH AUGUST VON (1805-1880), German geologist and palaeontologist, was born at Eisleben in Saxony on the 9th of July 1809. He was educated at Berlin, and after having acted as assistant in the mineralogical museum he was appointed professor of mineralogy and geognosy in the university of Tübingen in 1837, a post which he occupied until his death. His earlier work related chiefly to crystallography and mineralogy, on which subjects he published textbooks that were widely used. He became distinguished for his researches on palaeontology, and especially for those on the fossils of the Jurassic system. The museum at Tübingen owed its establishment to his exertions. He died at Tübingen on the 21st of December 1889.

His chief publications were: Method der Kristallographie (1840); Das Fläsengebirge Württembergs (1843); Petrefaktenkunde Deutschlands (7 vols. and atlas, 1846-84); Die Cephalopoden Deutschlands (Petrefakt, Band IV) (4th ed. 1888-85); Der Jura (2 vols., 1885); Handbuch der Mineralogie (1855, 3rd ed. 1877); Die Ammoniten des Schwäbischen Jura (1883-84). Obituary by W. T. Blanford, Quart. Journ. Geol. Soc. vol. xlvii, 1890.

QUENTAL, ANTHEO DE (1842-1901), Portuguese poet, was born on the island of St Michael, in the Azores, on the 18th of April 1842. He studied at the university of Coimbra, and soon distinguished himself by unusual talent, as well as by the prodigiousness of his writings. He began to write poetry at an early age, chiefly, though not entirely, devoting himself to the sonnet. After the publication of one volume of verse, he entered with great warmth into the revolt of the young men which dethroned Castilho, the chief living poet of the elder generation, from his place as dictator over modern Portuguese literature. He then travelled, engaged on his return in political and socialistic agitations, and found his way through a series of disappointments to the mild pessimism, a kind of Western Buddhism, which animates his latest poetical productions. His melancholy was increased by a spinal disease, which after several years of retirement from the world, eventually drove him to suicide in his native island, on the 11th of September 1891. Antheo stands at the head of modern Portuguese poetry after João de Deus. His principal defect is monotonity—his own self is his solitary theme, and he seldom attempts any other form of composition than the sonnet. On the other hand, few poets who have written so much have so profusely utilized the form thus produced so large a proportion of really exquisite work. The comparatively few pieces in which he either forgets his doubts and inward conflicts, or succeeds in giving them an objective form, are among the most beautiful in any literature. The purely introspective sonnets are less attractive, but equally finely wrought, interesting as psychological studies, and impressive from their sincerity. His mental attitude is well described by himself as "the effect of Germanism on the unprepared mind of a Southerner." He had learned much, and half-learned more, which he was unable to assimilate, and his mind became a chaos of conflicting ideas, settling down into a condition of gloomy negation, save for the one conviction of the vanity of existence, which ultimately destroyed him. A healthy participation in public affairs might have saved him, but he seemed incapable of entering upon any course that did not lead to delusion and disappointment. The great popularity acquired, notwithstanding, by poetry so metaphysical and egotistic is a testimony to the artistic instinct of the Portuguese.

As a prose writer Quental displayed high talents, though he
wrote little. His most important prose work is the Consent.<br>
derations sobre a philosophia da historia literaria Portugueza,<br>but he earned fame by his pamphlets on the Coimbra question,<br>Bom senso e bom gosto, a letter to Castilho, and A dignidade das<br>letras e literaturas oficiaes.<br>
His friend Oliveira Martins edited the Sonnets (Oporto, 1886),<br>supplying an extensive, critically selective, and interesting collec-<br>tion of studies on the poet by the leading Portuguese writers appeared in<br>a volume entitled Anhiero de Quental. In Memoriam (Oporto, 1896).<br>The sonnets have been turned into most European languages; to<br>English by Edgar Prestage (Anhiero de Quental, Sixty-four Sonnets,<br>London, 1894), together with a striking autobiographical letter<br>addressed by Quental to his German translator, Dr Storck.<br>
QUERARD, JOSEPH MARIE (1797–1865), French bibliog-<br>rapher, was born at Rennes on the 25th of December 1797.<br>He was apprenticed to a bookseller in his native town, and was<br>sent abroad on business. He remained in Vienna from 1819 to<br>1824, and there drew up the first volumes of his great work,<br>La France littéraire, ou Dictionnaire bibliographique des savants,<br>historiens, et gens de lettres de la France, &c. (10 vols., 1826–1842),<br>dealing especially with the 18th and early 19th centuries, which<br>he was enabled to complete by a government subsidy granted by<br>Guizot in 1830, and by the help of the Russian bibliophile Serge<br>Poltoratsky. The firm of Didot, who were his publishers, took<br>out a new list, an alphabetical dictionary of contemporary authors,<br>which he had intended to complete his work, and placed it<br>with Ch. Louandre and F. Bourquelot. Querard averaged himself by<br>pointing out the errors of his successors. In spite of<br>his claims Querard was unable to secure a position in any of<br>the public libraries. He died in Paris on the 3rd of December<br>1865.

Among his other works are: Les surchercies littéraires dévoilées<br>(5 vols., 1845–56); Bibliographie La Menaisienne (1849); Diction-<br>naire des ouvrages-polyonymes et anonymes de la littérature francaise,<br>1700–1848; an additional volume to La France littéraire<br>entitlý Ecrivains pseudonymes, &c. (1854–56). See Mar. Jozon<br>d‘Erquar, Querard, in La France littéraire (1854), vol. xi.

QUERCITRON, a yellow dyestuff obtained from the bark of<br>the quercitron oak, Quercus tinoaria, a fine forest tree indigenous<br>in North America. The name is a shortened form of "querci-<br>trion," from Lat. quercus, oak, and "citron," and was invented by<br>Dr Edward Bancroft (1744–1821), who by act of parliament in<br>1785 was granted special privileges in regard to the importa-<br>tion and use of the substance. The dyestuff is prepared by<br>grinding the bark in mills after it has been freed from its black<br>epidermis layer, and sifting the product to separate the fibrous<br>matter, the fine yellow powder which remains forming the<br>quercitron of commerce. The ruddy-orange decoction of querci-<br>trion contains quercitrin acid, whence its use in tanning, and an<br>active dyeing principle, quercitrin, C_{20}H_{20}O_{9}. The<br>latter substance is a glucoside, and in aqueous solution under<br>the influence of mineral acids it yields quercetin, C_{15}H_{16}O_{9}, which is<br>precipitated, and the pentoside rhamnose. Quercetin is a<br>crystalline powder of a brilliant citron yellow colour, entirely<br>insoluble in cold and dissolving only sparingly in hot water, but<br>quite soluble in alcohol. Either by itself or in some form of<br>its glucoside quercitrin, quercitin is found in several vegetable<br>substances, among others in chicory, in Persian berries (Rhamnus<br>catharticus), buckwheat leaves (Polygonum Fagopyrum), Zante<br>fuscin wood (Rhus Coitus), and in rose petals, &c. Quercitron<br>was first introduced as ã yellow dye in 1775, but it is principally<br>used in the form of flavia, which is the precipitate thrown down<br>from a brown decoction of quercitrin by sulphuric acid.<br>Chemically, quercitin is a member of a fairly large class of<br>natural colouring matters derived from ß phenyl benzo-y-pyrone<br>or flavone, the constitution of which following on the researches<br>of St von Kostanecki, A. G. Perkin, Herzog, Goldschmidt and<br>others. Among the related colouring matters are: chrysian<br>from poplar buds, apigenin from parsley, luteolin from weld and<br>dyers’ broom, fisetin from young fustic and yellow cedar,<br>galangin from galanga root, and myricetin from Myrica Nig.

QUERCY (Lat. pagus Catusrinum, Fr. Cahorsin), a county<br>in France before the Revolution. The name is taken from that of<br>a Gallic tribe, the Cadurci, and was applied to a small<br>district watered by the Dordogne, the Lot and the Tarn. It<br>was bordered by Limousin, Rouergue, Armagnac, Périgord and<br>Agenais. In the middle ages it was divided into upper, or<br>black, Quercy, and lower, or white, Quercy, the capital of the<br>former being Cahors and of the latter Montauban. Its two<br>other chief towns were Figeac and Moissac. Ecclesiastically it<br>was included almost entirely in the diocese of Cahors until<br>1317, when a bishopric for lower Quercy was established at<br>Montauban. Judicially it was under the authority of the<br>parlement de Bordeaux; for financial purposes it was part of the<br>généralité of Montauban. The estates of the county had the<br>bishop of Cahors for president; other members were the bishop<br>of Montauban and other ecclesiastics, four viscounts, four barons<br>and some other lords and representatives of eighteen towns.<br>

Under the Romans Quercy was part of Aquitania prima, and<br>Christianity was introduced therein during the 4th century.<br>Early in the 6th century it passed under the authority of the<br>Franks, and in the 9th century was part of the Frankish<br>kingdom of Aquitaine. At the end of the 10th century its<br>rulers were the powerful counts of Toulouse. During the<br>wars between England and France in the reign of Henry II.,<br>the English placed garrisons in the county, and by the treaty of<br>Paris in 1259 lower Quercy was ceded to England. Both the<br>king of England and the king of France confirmed and added<br>to the privileges of the towns and the district, each thus<br>hoping to attach the inhabitants to his own interest. In 1360,<br>the treaty of Brétigny, the whole country passed to England,<br>but in 1440 the English were finally expelled. In the 16th<br>century Quercy was a stronghold of the Protestants, and the<br>scene of a savage religious warfare. The civil wars of the<br>regime of Louis XIII. centred around Montauban. Quercy<br>was early an industrial district. It gave its name to<br>caducum, a kind of light linen, and the bankers of Cahors<br>were famous.

QUERÉTARO, a city of Mexico, capital of the state of<br>Querétaro-Arteaga, 152 m. by rail N.W. of the national capital,<br>Pop. (1900) 33,152, including a large Indian element. Querétaro<br>is served by the Mexican Central railway. The city stands on a<br>plain at the foot of the Cerro de las Campanas, 6168 ft.<br>above sea-level. Among the important buildings are the<br>Cathedral (said to have been built originally about 1535, and<br>subsequently restored at various times), the Iturbide theatre<br>(in which occurred the trial of Maximilian), the government<br>offices, the federal palace and the church of Santa Rosa,<br>Santa Clara and San Augustin. The federal palace and the<br>church of Santa Rosa are examples of the work of the celebrated<br>Mexican architect, Francisco Eduardo de Tresguerras (1765–<br>1833), who restored the church of Santa Clara also. The<br>gilded wood carvings of Santa Clara are noteworthy; and in<br>the courtyard of the federal palace there are other specimens<br>of the same work. The water-supply is brought over a fine<br>aqueduct 5 m. long, dating from 18th century. Among<br>manufactures are cottons, woolens, pottery and ironwares.<br>Querétaro has one of the oldest and largest cotton factories<br>in Mexico, employing about 2000 operatives, and maintaining<br>a small private military force for protection. It was built<br>in the days when brigandage held the whole country in terror,<br>and was strongly fortified and provided with artillery and<br>garrison. The latter was also used to escort pack trains of<br>goods and supplies before the building of the railway. This<br>old factory has also played its part in the civil wars of the<br>country, and in every war whenever Querétaro became involved in military operations.<br>Querétaro occupies the site of an Otomí Indian town dating from<br>about 1400. It was captured by the Spanish in 1531 and<br>was raised to the rank of a city in 1655. It was the scene of a<br>revolutionary outbreak against Spain in 1810. In 1848 a Mexican congress met here to ratify the treaty of peace with<br>the United States, and in 1867 Querétaro was the scene of<br>Maximilian’s last stand against the republicans (under Escobedo),<br>which resulted in his capture and subsequent execution on<br>the Cerro de las Campanas just N. of the city.
QUERÉTARO-ARTEAGA—QUENARY

QUERÉTARO-ARTEAGA, a central state of Mexico, bounded N. by San Luis Potosí, E. by Hidalgo, S.E. by the state of Mexico, S. by Michoacán and W. by Guanajuato; area, 3535 sq. m. Pop. (1900) 233,389, largely Indian. The state belongs to the elevated plateau region, with its semi-arid conditions. The N. part of the state is traversed from E. to W. by the wooded Sierra Gorda, whose spur reach southward to the central districts. The central and S. parts are covered by plains, broken by low hills. The rivers are small and flow chiefly to the San Juan, a part of the Panuco drainage basin. There are some small lakes and swamps and a number of mineral springs. Sugar, cotton, Indian corn, beans and considerable quantities of wheat are grown, but agriculture is largely hampered by the uncertainty of the rainfall. The chief wealth of the state is in its mines. Silver, gold, copper, mercury, lead, tin, antimony and precious stones are found, in some cases in very rich deposits. The richest mining districts are those of Cadereyta and Tolimán, where there are metallurgical works for the reduction of ores. The Mexican Central and Mexican National railways cross the S. end of the state and afford transportation facilities for the agricultural districts, but the other districts, N. are still dependent upon old methods. The capital of the state is the historic city of Querétaro (q.v.), and other important towns, with their populations in 1900, are: San Juan del Río (5124), Landa (about 7000), Ahuacatlan (5929 in 1895), Jalpan (about 6000), and Tolimán, celebrated for its opals.

QUERFURT, a town of Germany, in the province of Prussian Saxony, situated in a fertile country on the Querne, 18 m. W. from Merseburg, on a branch line from Obersorbiingen. Pop. (1905) 2884. Its chief industries are sugar-refining, lime-burning and brewing. Querfurt was for some time the capital of a principality which had an area of nearly 200 sq. m. and a population of about 20,000. The ruling family having become extinct in 1496, it passed to that of Mansfeld. In 1533, by the peace of Prague, it was ceded to the elector of Saxony, John George I., who handed it over to his son Augustus of Saxe-Weissenfels; but in 1746 it was again united with electoral Saxony. It was incorporated with Prussia in 1813.

See Schneider, Querfurter Stadt- und Kreischronik (Querfurt, 1902).

QUERN, the primitive form of hand-mill for grinding corn, consisting of two flat circular stones; the lower stone, often shaped with a rim, has a wooden or metal pin in the centre which passes through a hole in the upper stone; the worker pours the grain through the hole with one hand, revolving the upper stone with the other by means of a peg fixed to one side. The Old English word is cwaern; it is a word common to Teutonic languages, cf. Du. kwaern, Swed. qvarn and various forms in Old German; cognate words are found in Slavonic languages pointing to a pre-Aryan root. It is not related to "churn." (See FLOUR.)

QUESADA Y MATHEUS, JENARO DE (1818-1880), 1st MARQUIS OF MIRAVALDES, Spanish soldier, was born at Santander, on the 6th of February 1818. He was a son of General Vicente Quesada, a Conservative officer who was murdered and atrociously mutilated in the streets of Madrid by a revolutionary mob in the early days of Queen Isabella's reign. At Quesada belonged to an ancient family connected with the dukes of Fernan Nuñez, he was made a cortes when only six years old, was educated at the seminary for nobles and in 1833 was promoted lieutenant in the 1st Foot Guards. He served from 1835 to 1836 against the Carlists. When his father was assassinated in 1836 he resigned, went to France, got employed in a mercantile firm and was only permitted to return to the army in 1837 by his relatives, who got him a company in the guards. He distinguished himself often in the Carlist war, but his promotion was slow, and he declined to have anything to do with politics. He confined himself to his duties as a soldier, always fighting on the side of governments against Carlist, Republican and Progressist risings. He only became a general of division in 1853, and at the head of the Madrid garrison he fought hard in 1854 to avert the triumph of Espartero, O'Donnell and Dulce, who publicly recognized his gallant conduct. When the war in Morocco broke out, Marshal O'Donnell gave Quesada the command of a division, which played so conspicuously a part in that campaign and at the battle of Wad el Ras that its commander was made a grand cross of Charles III. He was director-general of the Civil Guard when the military rebellion of the 22nd of June 1866 broke out in Madrid, and after he had been wounded in the leg he remained at the head of the loyal troops until the insurgents were crushed. He did not accept any military post during the revolution until Marshal Serrano in 1874 offered him the direction of the staff, and he only accepted it after clearly stating that he was a royalist and partisan of Alfonso XII. In his long and brilliant career he never swerved from his steadfast resolve never to be mixed up in any political or military intrigues or pronunciamientos—"to use his own words, "not even to restore my king." As soon as the king was restored, the government of Señor Canovas made Quesada first general-in-chief of the army of Central Spain, and in February 1875 general-in-chief of the army of the North. With the assistance of another officer who also had never dabbled in pronunciamientos, General O'Ryan, Quesada restored discipline in the armies confronting Don Carlos, and for twelve months concerted and conducted the operations that forced the pretender to retire into France and his followers to lay down their arms. The government confined to the marquis of Miravaldes the difficult task of ruling the northern provinces for several years after the war, and he succeeded in conciliating the sympathies of the Basques and Navarrese, though the penalty of their last rising had been the loss of most of their ancient liberties or fueros. Quesada was made marquis of Miravaldes, grandee after the war, minister of war in 1883 and senator. Though he was a strict, stern disciplinarian of the old school and an unflinching Conservative, Catholic and royalist, even his political and military opponents respected him, and were proud of him as an unblemished type of the Castilian soldier and gentleman. He died at Madrid on the 19th of January 1889, and was given full military honours.

QUESNAY, FRANÇOIS (1694-1774), French economist, was born at Méréc, near Paris, on the 4th of June 1694, the son of an advocate and small landed proprietor. Apprenticed at the age of sixteen to a surgeon, he soon went to Paris, studied medicine and surgery there, and, having qualified as a master-surgeon, settled down to practice at Mantes. In 1737 he was appointed perpetual secretary of the academy of surgery founded by François la Peyrone, and became surgeon in ordinary to the king. In 1744 he graduated as a doctor of medicine; he became physician in ordinary to the king, and afterwards his first consulting physician, and was installed in the palace of Versailles. His apartments were on the entresol, whence the Réunions de l'entresol received their name. Louis XV. esteemed Quesnay much, and used to call him his thinker; when he ennobled him he gave him for arms three flowers of the pansy (pensée), with the motto Propter excogitationem mentis.

He now devoted himself principally to economic studies, taking no part in the court intrigues which were perpetually going on around him. About the year 1750 he became acquainted with Jean C. M. de Gournay (1712-1750), who was also an earnest inquirer in the economic field; and round these two distinguished men was gradually formed the philosophical sect of the Économistes, or, as for distinction's sake they were afterwards called, the Physiocrates. The most remarkable men in this group of disciples were the elder Mirabeau and Nicolas de Condorcet (1743-1794), and Antoine Quesnay (1756-1759), Nicolas Baudeau (Introduction à la philosophie économique, 1751), G. F. Le Trosne (De l'ordre social, 1777), André Morelet (best known by his controversy with Galiani on the freedom of the corn trade), Mercier Lariviûre and Dupont de Nemours. Adam Smith, during his stay on the continent with the young duke of Bucheuch in 1764-66, spent some time in Paris, where he made the acquaintance of...
QUESNAY—QUETTA

Quesnay and some of his followers; he paid a high tribute to their scientific services in his Wealth of Nations. Quesnay died on the 16th of December 1774, having lived long enough to see his great pupil, Turgot, in office as minister of finance. He had married in 1718, and had a son and a daughter; his grandson by the former was a member of the first Legislative Assembly.

The publications in which Quesnay expounded his system were the following:—two articles, on "Fermiers" and on "Grains," in the Encyclopédie of Diderot and D'Alembert (1756, 1757); a discourse on the law of nature in the Physiocratie de ses Compatriotes (1766); Maximes générales de gouvernement économique d'un royaume agricole (1758), and the simultaneously published Tableau économique avec son explication, ou extrait de l'économies royale d'un pays, ou, "Les économistes... pauvre royaume; pauvre royaume..."; Dialogue sur le commerce et les travaux des artisans; and other minor pieces. The Tableau économique, though on account of its dryness and abstract form it met with little general favour, may be considered the principal manifesto of the school. It was regarded by the followers of Quesnay as entitled to a place amongst the foremost productions of human wisdom, and is named by the elder Mirabeau, in a passage quoted by Adam Smith, as one of the three great inventions which have contributed most to the stability of political societies, the other two being those of writing and of money.

Its object was to exhibit by means of certain formulas the way in which the state of society as a whole and the situation of each individual would in a state of perfect liberty be distributed among the several classes of the community (namely, the productive classes of the proprietors and cultivators of land, and the unproductive classes comprising manufacturers and merchants), and to represent by other formulas the modes of distribution which take place under systems of Governmental restraint and regulation, with the evil results arising to the whole society from different degrees of such violations of the natural order. Quesnay's assumptions are too well known. He views that the one thing deserving the solicitude of the practical economist and the statesman is the increase of the net product; and he infers also what Smith afterwards affirmed, on quite the contrary, that this interest of the landowner is "strictly and indissolubly connected with the general interest of the society."

A small édition de luxe of this work, with other pieces, was printed in 1758 in the palace of Versailles under the king's immediate superintendence; it was named the "Memoires du roi, adressee a la nation...". Already in 1767 the book had disappeared from circulation, and no copy of it is now procurable; but the substance of it has been preserved in the Ami des hommes de Mirabeau, and the Physiocratie de Dupont de Nemours.

His economic writings are collected in the 2nd vol. of the Principaux économistes, published by Guillaumin, Paris, with preface and notes by Eugène Daire; also his Œuvres économiques et philosophiques, published by C. J. Oncken (Frankfort, 1889); a facsimile reprint of the Tableau économique, from the original MS., was published by the British Economic Association (London, 1893). His other writings were the Philanthropie de l'homme... avec l'évidence des vérités géométriques, with a Projet de nouveaux éléments de géométrie, 1773. Quesnay's Êloge was pronounced in the Academy of Sciences by Grandjean de Fouchy (see the Recueil of that Academy, 1774). See also F. J. Marmontel, Mémorials; Mémorials de Mme. de Housset; H. Higges, The Physiocrats (London, 1897).

QUESNAL, PASQUIER (1634-1710), French Jansenist theologian, was born in Paris on the 14th of July 1634, and, after graduating in the Sorbonne with distinction in 1653, joined the French Oratory in 1657. There he soon became prominent; but his Jansenist sympathies led to his banishment from Paris in 1658. He took refuge with the friendly Cardinal Cosin, bishop of Orleans; four years later, however, foreseeing that a fresh storm of persecution was about to burst, he fled to Brussels, and took up his abode with Antoine Arnauld (q.v.). There he remained till 1703, when he was arrested by order of the archbishop of Malines. After three months' imprisonment he made a highly dramatic escape, and settled at Antwerp, his adopted father's residence. Arnauld's death in 1694 Quesnal was generally regarded as the leader of the Jansenist party; and his Réflexions morales sur le Nouveau Testament played almost as large a part in its literature as Jansen's Augustinus itself.

As its title betokens, this was a devotional commentary on the Scriptures, wherein Quesnay managed to explain the aims and ideals of the Jansenist party better than any earlier writer had done; and it accordingly became the chief object of Jesuit attack. It appeared in many forms and under various titles, the original germ going back so far as 1668; the first complete edition was published in 1692. The bull Unigenitus, in which no fewer than 101 sentences from the Réflexions morales were condemned as heretical, was obtained from Clement IX. on the 8th of September 1713. Quesnal died at Amsterdam on the 2nd of December 1719.

ST. C.

QUETELET, LAMBERT ADOLPHE JACQUES (1796-1874), Belgian astronomer, meteorologist and statistician, was born at Ghent on the 22nd of February 1796, and educated at the lyceum of that town. In 1819 he was appointed professor of mathematics at Ghent, and the following year he became librarian at the newly created museum of science and literature, and he continued to hold that post until the museum was absorbed in the free university in 1834. In 1828 he was appointed director of the new royal observatory which it had been decided to found, chiefly at his instigation. The building was finished in 1832, and the instruments were ready for work in 1835, from which date the observations were published in 40 volumes (Annales de l'Observatoire Royal de Bruxelles), but Quetelet chiefly devoted himself to meteorology and statistics. From 1834 he was perpetual secretary of the Brussels Academy, and published a vast number of articles in its Bulletin, as also in his journal, Correspondance mathématique et physique (11 vols., 1835-39). He died at Brussels on the 17th of February 1874. His son, Ernest Quetelet (1825-78), was from 1856 attached to the observatory, and on his death succeeded him as director. He made a great number of observations of stars with proper motion.

Quetelet's astronomical papers refer chiefly to shooting stars and similar phenomena. He organised extensive magistral and meteorological observations, and in 1839 he started regular observations of the periodic phenomena of vegetation, especially the flowering of plants. The results are given in various memoirs published orderly in Brussels Academy, and in his works sur le climat de la Belgique et sur la physique du globe (the latter forms vol. xiii. of the Annales, 1861). He is, however, chiefly known by the statistical investigations which occupied him from 1823 onward. In 1855 he published his principal work, Sur l'homme et le développement de ses facultés, ou essai de physiologie sociale (2nd ed., 1869), containing a resumed of his statistical researches on the development of the physical and intellectual qualities of man, and on the "average man" (homme moyen), which has become known as the normal man. In 1866 he brought out his Lettres à S. A. R. le duc rgnant de Saxe- Coburg and Gotha on la théorie des probabilités appliquée aux sciences morales et politiques (of which Sir J. Herschel wrote a full account in the Edinburgh Review, 1867). Quetelet in 1848 gave the extreme social and des lois qui le régissent. In these works he shows how the numbers representing the individual qualities of man are grouped round the numbers referring to the "average man" in a manner exactly corresponding to that in which single results of observation are grouped round the mean result, so that the principles of the theory of probabilities may be applied to statistical researches on the subjects. These ideas are further developed in various papers in the Bulletin and in his L'Anthropométrie, ou mesure des différentes facultés de l'homme (1871), in which he lays great stress on the universal applicability of the binomial law,—according to which the number of cases in which, for instance, a certain height occurs among a large insample is proportional to the ordinate of a curve (the binomial) symmetrically situated with regard to the ordinate representing the mean result (average height). A detailed Essai sur la vie et les travaux de L. A. J. Quetelet, by his pupil and assistant E. Mauy, was published at Brussels in 1875.

QUETTA, the capital of British Baluchistan, India, which also gives its name to a district. It rose to prominence in 1876, when Sir Robert Sandeman founded a residency there in the word kotal, signifying a fortress, and the place is still locally known as Shal Kot. Quetta is the southernmost point in the line of frontier posts and system of strategic railways on the north-west frontier of India, 536 m. by rail N. of Karachi. It forms the headquarters of the fourth division of the southern army, with a strong garrison of all arms. The railway was built in 1879, with a view to its continuance to Kandahar; but its present terminus is New Chaman on the Afghan border. A branch line to Nushki was completed in 1905. The cantonnement and
The lucerne, largely ranging &c; The wig, set settlements worn it the government duties from the Khojak Pass and Kandahar. Southwards is the open valley leading to the Bolan Pass, traversed by the railway. North of Quetta is the open plain leading to Pishin and the Haruai, also traversed by the Sibi-Pishin railway, which passes through the fortifications. These defensive works, stretching from the base of Takatu to the foot of the Mashelek hills on the west, bar the way to advance from the Khojak Pass. During the last quarter of the 19th century Quetta grew from a dilapidated group of mud buildings, with an inferior bazaar and a few scattered remnants of neglected orchard cultivation, into a strong fortress, and one of the most populous stations of the Indian army. Quetta was visited by the prince of Wales (George V.) in 1906, and a staff college for the Indian army was opened here in 1907. It has become the trade mart for western Afghanistan, eastern Persia, and much of central Asia. The population of the town and cantonment in 1901 was 24,584.

The District of Quetta (including Pishin) has an area of 5127 sq. m. Pop. (1901) 114,087, of whom more than three-fourths are Afghans, showing an increase of 45% in the decade. The general aspect of the country is hilly, rocky and sterile, particularly towards the north; but in many parts the soil is rich and good, yielding wheat, rice, madder, tobacco, and lucerne, besides numerous grasses. The district has abundant orchards, furnishing grapes, apples, pears, pomegranates, figs, &c.; melons and all kinds of English vegetables are also largely cultivated. The valley is watered by the Pishin Lora and by government irrigation works, including artesian wells. Wild sheeps and goats abound in the hills of the district. The climate appears to be healthy and the temperature moderate, ranging from 40° F. in the winter to about 78° in the summer. The annual rainfall (including snow) averages about 10 in. The actual line of valley which contains Quetta and the Bolan Pass was originally rented from the Khals of Kalon on terms which were changed in 1882 to a quit-rent of Rs25,000 per annum, and a further compensation of Rs10,000 in lieu of transit duties in the Bolan Pass. This perpetual leasehold was afterwards extended so as to include Nushki and give the British government the command of the trade route to Sistan. The Quetta district is now administered, together with the assigned districts of Pishin, Tal Chotiali, and Sibi (assigned by the treaty of Gandamak as being nominally Afghan territory) by a regular staff of civil officials.

See Thornton, Life of Sir Robert Sandeman (London, 1866); Quetta-Pishin District Gazetteer (Ajmer, 1907). (T. H. H.)

**QUEUE or CUE** (from Fr. queue, O. Fr. cue, Lat. creba, tail), a tail of hair, either of the natural hair when so worn or of a wig, plaited together and tied with ribbon, hanging down the back of the neck. In Europe and European colonies and settlements this method of wearing the hair prevailed after the heavy periwig had gone out of fashion. The bob-wig or tie-queue with the queue survives in the English barrister's wig. In the second half of the 18th century the queue was worn thick and short and sometimes encased in leather, when it was termed a "club." In the navy and army the queue survived its disuse in civil life. The three pieces of black velvet sewn on to the collar of the full dress tunic of the officers of the Royal Welsh Fusiliers, and styled the "flash," are said to be a relic of the ribbon which tied the queue. The most familiar use of this fashion of wearing the hair is the pigtail of the Manchus, which was imposed on all Chinese men as a symbol of loyalty and obedience at the conquest of China (see CHINA: Social Life). A particular meaning of the word is for the line of persons formed in order awaiting their turn for admission to a theatre or other place. This appears also in French, from which it is borrowed. In the form "cue" (Fr. queue) the word is used of the tapering, striking implement in the game of billiards (q.v.). It is often stated that the theatrical use of "cue" for the concluding words of an actor's dialogue or speech which marks the beginning of another actor's part is merely an adaptation of the meaning "tail." The New English Dictionary points out that there is no trace of this use in French. In 16th and 17th century plays the endings of parts are marked Q. or qu-, which has been taken to represent Lat. quando, when.

**QUEVEDO Y VILLEGAS, FRANCISCO GÓMEZ DE** (1580-1645), Spanish satirist and poet, was born at Madrid, where his father, who came from the mountains of Burgos, was secretary to Anne of Austria, fourth wife of Philip II. Early left an orphan, Quevedo was educated at the university of Alcalá, where he acquired a knowledge of classical and modern tongues —of Italian and French, Hebrew and Arabic, of philosophy, theology, civil law, and economics. His fame reached beyond Spain; at twenty-one he was in correspondence with Justus Lipsius on questions of Greek and Latin literature. His abstruse studies influenced Quevedo's style; to them are due the pedantic traits and mania for quotations which characterize most of his works.

He betook himself to the court and mingled with the society that surrounded Philip III. The cynical grief of ministers, the meanness of their flatterers, the corruption of the royal officers, the financial scandals, afforded ample scope to Quevedo's talent as a painter of manners. At Valladolid, where the court resided from 1601 to 1606, he mingled freely with these intrigues and disorders, and lost the purity of his morals but not his uprightness and integrity. In 1611 he fought a duel in which his adversary was killed, fled to Italy, and later on became secretary to Pedro Téllez Girón, duke of Osuna, and vicerey of Naples. Thus he learned politics—the one science which he had perhaps till then neglected,—initiated himself into the questions that divided Europe, and penetrated the ambitions of the neighbours of Spain, as well as the secret history of the intrigues protected by the favour of Philip III. The result was that he wrote several political works, particularly a lengthy treatise, La Política de Dios (1626), in which he lays down the duties of politics by displaying to them how Christ has governed His church. The disgrace of Osuna (1620) compromised Quevedo, who was arrested and exiled to his estate at La Torre de Juan Abad in New Castile. Though involved in the process against the duke, Quevedo remained faithful to his patron, and bore banishment with resignation. On the death of Philip III. (31st of March 1621) he recommended himself to the first minister of the new king by celebrating his accession to power and saluting him as the vindicator of public morality in an epistle in the style of Juvenal. Olivares recalled him from his exile and gave him an honorary post in the palace, and from this time Quevedo resided almost constantly at court, exercising a kind of political and literary jurisdiction due to his varied relations and knowledge, but especially to his biting wit, which had no respect for persons. General politics, social economy, war, finance, literary and religious questions, all came under his dissecting knife, and he had a dissertation, a pamphlet, or a sonnet for almost anything. One day he is defending St James, the sole patron of Spain, against a powerful coterie that wished to associate St Theresa with him; next day he is writing against the duke of Savoy, the hidden enemy of Spain, or against the measures taken to change the value of the currency; or once more he is engaged with the literary school of Góngora, whose affections seem to him to sin against the genius of the Castilian tongue. And in the midst of this incessant controversy on every possible subject he finds time to compose a picaresque romance, the Historia de la Vida del Busón, llamado Don Pablos, Exemplo de Vagamundos, y Espejo de Tacatos (1626); to write his Suenos (1627), in which all classes are flagellated; to pen a dissertation on The Constancy and Patience of Job (1631), to translate St Francis de Sales and Seneca, to compose thousands of verses, and to correspond with Spanish and foreign scholars.

But Quevedo was not to maintain unscathed the high position won by his knowledge, talent, and biting wit. The government
of Olivarés, which he had welcomed as the dawn of a political and social regeneration, made things worse instead of better, and led the country to ruin. Quevedo saw this and could not hold his peace. An anonymous petition in verse enumerating the grievances of his subjects was found, in December 1639, under the very napkin of Philip IV. It was shown to Olivarés, who exclaimed, "I am ruined!"; but before his fall he sought vengeance on the libeller. His suspicions fell on Quevedo, who had enemies glad to confirm them. Quevedo was arrested on December 7, and carried under a strong escort to the monastery of St Mark at Leon, where he was kept in rigorous confinement till the fall of the minister (January 1643) restored him to light and freedom, but not to the health which he had lost in his dungeon. He had little more than two years to live, and these were spent in inactive retreat, first at La Torre de Juan Abad, and then at the neighbouring Villanueva de los Infantes, where he died September 8, 1645.

As a satirist and humorist Quevedo stands in the first rank of Spanish writers; his other literary work does not count for much. J. L. Chifflet, in a letter of February 2, 1629, calls him "a very learned man to be a Spaniard," and indeed his erudition was of a solid kind, but he merits attention not as statesman, philosopher, and moralist, but as the keen polemic writer, the pitiless mocker, the profound observer of all that is base and absurd in human nature, and at the same time as a finished master of style and of all the secrets of the Spanish tongue. His style, indeed, is not absolutely pure; though he ridiculed so well the bad taste of culturismo, he fell himself into the style called concepcionismo, which strains after ambiguous expressions and alembrad "points." But, though involved and overcharged with ideas, his diction is of singular force and originality; after Cervantes he is the greatest Spanish prose writer of the 17th century.

There is an excellent collected edition of Quevedo's prose works with a good life of the author by D. Aureliano Fernandez-Guerra (Bibl. Ribadeneyra, vols. xxi. and xlvii.); his poetical works in vol. ix. of the same collection are badly edited by D. Florencio Janer. There is a second edition, enlarged and annotated by Señor Menendez y Pelavo. E. Mereim, in Ensai sobre la vida et les erreurs de Francisco de Quevedo (Paris, 1886), has supplied an excellent critical and biographical monograph with a bibliography. (J. F. K.)

QUEZAL, or Quetzal, the Spanish-American name for one of the most beautiful of birds, abbreviated from the Aztec or Maya Quetzal-totol, the last part of the compound word meaning fowl, and the first, also written Quetzal, the long feathers of rich green with which it is adorned. The Quetzal is one of the Trogons (q.v.), and was originally described by Hernandez (Historia, p. 13), whose account was faithfully copied by F. Willughby. Yet the bird remained practically unknown to ornithologists until figured in 1825, from a specimen belonging to Leadbeater, by J. C. Temminck (Pl. col., 372), who, however, mistakenly thought it was the same as the Trogon pavoninus, a congenic but quite distinct species from Brazil, that had just been described by Spix. The scientific determination of the Quetzal-bird of Central America seems to have been first made by C. L. Bonaparte in 1826, as Trogon paradisus, according to his statement in the Zoological Society's Proceedings.

1 The Mexican deity Quetzal-coatl had his name, generally translated "Feathered Snake," from the quetzel, feather, or bird, and coatl, snake, as also certain kings or chiefs, and many places, e.g. Quetzalapan, Quetzaltepec, and Quetzaltenango, though perhaps some of the last were named directly from the personages (cf. Bancroft, Native Races of the Pacific States, vol. v., Index). Quetzaltzli is said to be the emerald.

2 This specimen had been given to Canning (a tribute, perhaps, to the statesman who boasted that he had "called a New World into existence to redress the balance of the Old") by Mr Schenley, a diplomatist, and was then thought to be unique in Europe; but, according to those which had reached Spain, where they lay neglected and undescribed, James Wilson says (Illustr. Zoology, pl. vi. text) that others were brought with it, and that one of them was given to the Edinburgh Museum. On the 21st day of the sale of Bullock's Museum in 1833, Lot 38 is entered in the Catalogue as "The Tail Feather of a magnificent undescribed Trogon," and probably belonged to this species.

3 De la llave's very rare and interesting memoir was reprinted by M. Sallé in the Revue et magasin de zoologie for 1861 (pp. 23-33).
QUEZALTENANGO—QUIBERON

747

bluish-green, were procured by Robert Owen (P. Z. S., 1860, p. 374; Ibis, 1861, p. 66, pl. ii. fig. 1); while further and fuller details of its habits were made known by O. Salvini (Ibis, 1861, pp. 138–149), from his own observation of this very local and remarkable species. Its chief home is in the mountains near Coban in Vera Paz, but it also inhabits forests in other parts of Guatemala at an elevation of from 2000 to 4000 ft.

The Quezal is hardly so big as a Turtle-Dove. The cock has a fine yellow bill and a head bearing a rounded crest of filamentosous feathers; lanceolate scapulars overhang the wings, and from the rump spring the long flowing plumes which are so characteristic of the species, and were so highly prized by the natives before the Spanish conquest that no one was allowed to kill the bird when taken, but only to divest it of its feathers, which were to be worn by the chiefs alone. These plumes, the middle and longest of which may measure from 5 ft. to 3½ ft., with the upper surface, the throat, and chest, are of a resplendent golden-green,1 while the lower part is vivid scarlet. The middle feathers of the tail, ordinarily concealed, are those of the Peacock, by the uropygials, are black, and the outer white with a black base. In the hen the bill is black, the crest more round and not filamentosous, the uropygials scarcely elongated, and the vent only scarlet. The eyes are of a yellowish-brown. Southern examples from Costa Rica and Veragua have the tail-coverts much narrower, and have been considered to form a distinct species, P. costaricensis. Among other species are P. antilasianus, P. fuligudas, P. auriceps and P. pavoennis, from various parts of South America, but though all are beautiful birds, none possess the wonderful singularity of the quezal.

(A. N.)

QUEZALTENANGO, the capital of the department of Quezaltenango, Guatemala, 70 m. by road W. of Guatemala city and at the terminus of a railway from Campero on the Pacific coast. Pop. (1905) about 31,000. It is situated on the river Sigua, and at the foot of the volcanic Santa Maria. It is the chief city in the republic, it has a large and cultural trade and manufactures of linen, woolen and cotton goods. It contains a fine cathedral and some good public buildings, including two national institutes for higher education; and it is well supplied with water and electricity for light and power. The majority of its inhabitants are Indians or half-breeds of Quiché descent. Quezaltenango was the capital of a Quiché kingdom, and was known as Xelahu or Xelahu until 1524, when it was conquered by the Spaniards under Pedro de Alvarado. In 1902 it was partially destroyed by an earthquake and an eruption of Santa Maria.

QUIBERON, CAMPAIGN AND BATTLE OF. Quiberon Bay, on the S. coast of Brittany, France, was the scene of the great naval battle which defeated the plan laid by the ministers of King Louis XV. of France, for the invasion of England in 1759, during the Seven Years' War (q.v.). An army had been collected at Vannes, in the south-east of Brittany, and transports had been brought together in the landlocked waters of the Morbihan which are connected with Quiberon Bay. The scheme of the French ministers was to combine twenty-one ships of the line lying at Brest under the command of M. de Conflans, with twelve which were to be brought round from Toulon by M. de la Clue. The army was then to be carried to some point on the coast of England or Scotland by the united squadrons. The British government was well informed of its enemy's intentions, and took vigorous measures of defence. Admiral Sir E. Hawke, afterwards Lord Hawke, was directed to blockade Brest with a fleet of twenty-five sail of the line, four ships of fifty guns and nine frigates. The four ships of fifty guns together with four frigates were detached, first under Commodore John Reynolds, and then under Commodore Robert Duff, to lie in Quiberon Bay and watch the entry to the Morbihan. The British government was well informed of its enemy's intentions, and took vigorous measures of defence. Admiral Sir E. Hawke, afterwards Lord Hawke, was directed to blockade Brest with a fleet of twenty-five sail of the line, four ships of fifty guns and nine frigates. The four ships of fifty guns together with four frigates were detached, first under Commodore John Reynolds, and then under Commodore Robert Duff, to lie in Quiberon Bay and watch the entry to the Morbihan. During the whole summer, from the beginning of June, Sir E. Hawke kept his station off Brest, and the detached squadron occupied Quiberon Bay. The task of blockading M. de la Clue at Toulon was given to Edward Boscawen, who had with him fourteen sail of the line. Boscawen reached his station on the 16th of May 1759. At the beginning of July want of stores and water, together with the injury inflicted on some of his vessels by a French battery, compelled him to go to Gibraltar to provision and refit. He reached the port on the 4th of August. On the 5th M. de la Clue left Toulon, and on the 17th passed the straits of Gibraltar, where he was sighted by the look-out ships of Boscawen. The British fleet hurried out to sea, and pursued in two divisions, separated by a distance of some miles owing to the haste with which they left port. During the night of the 17th and 18th of August five of M. de la Clue's ships lost sight of his flagship, and steered for Cadiz. The other seven, which had been delayed for a time in the hope of rejoining their consorts, were overtaken by Boscawen and attacked in the afternoon of the 18th. One, the "Centaur" (74), was captured after a very gallant resistance, in which the British flagship was severely damaged; during the night of the 18th–19th of August, two of the French ships altered course to the west, and escaped. The remaining four fled to the north, and into Portuguese waters, where two were driven ashore and destroyed, while two were captured near Lagos. The five in Cadiz were blockaded by Boscawen's second-in-command, Admiral Broderick. La Clue was mortally wounded, and died ashore in Portugal. Although the defeat of his squadron had ruined the scheme for the combination of their forces, the French ministers decided to persevere with the invasion. M. de Conflans was ordered to put to sea. On the 9th of November a severe gale forced Sir E. Hawke from in front of Brest, and as his ships were in want of stores he sailed for Torquay. Finding the way clear, Conflans put to sea on the 14th, and steered for Quiberon. Sir E. Hawke left Torquay to resume his station on the same day. On the 15th he learnt from a look-out ship that the French had been seen at sea to the north-west of Belleisle, and steering north-west Conflans met the Morbihan which he followed. Calms and contrary winds prevented either fleet from making much progress till the evening of the 19th, when the French were rather over 60 m. to the south-west of Belleisle, which is south of Quiberon. The wind had now changed to the north-west and was beginning to blow hard. M. de Conflans made for Quiberon under reduced canvas for fear of making the land in the night, the coast being one of the most dangerous in the world, on account of the rocky islands of Houat and Hoeldik, and the long string of reefs which lie inside Belleisle. Hawke was steering in the same direction farther out at sea. On the morning of the 20th of November, Conflans was near the south point of Belleisle. The small squadron of Commodore Duff, warned of his approach, endeavored to escape to sea before he could shut them in at Quiberon. One of the ships worked out through the very dangerous passage to the north of Belleisle; the others came round the south of the island, where they were nearly cut off and captured. As the pursuers came close to them the sails of Hawke's fleet were seen rising over the horizon. M. de Conflans immediately called off the pursuers, and endeavored to form his line of battle. By midday he was able to estimate the full strength of Hawke's fleet of twenty-three sail of the line, which with the four 50-gun ships of Commodore Duff made twenty-seven vessels to his twenty-one. He therefore altered his mind, and decided to run inside the islands of Houat and Hoeldik, and gain the anchorage of Quiberon. He concluded that as the day was far advanced and the wind was increasing, the British admiral would not dare to follow him into so dangerous a place. But Sir E. Hawke considered that the circumstances justified him in taking all risks, and seeing his enemy in retreat he ordered a pursuit. As the van of the French led by their admiral was turning inside the Cardinal rocks at the southern end of the reefs, his rear was attacked. The two fleets entered the Bay late in the evening, and there followed a battle unique in naval history, for it was fought in the dark, among rocks, in a severe gale, and on a lee shore. Two of the British liners were wrecked on a rock called the Four, but five of the French were taken or...
destroyed, among the latter was the flagship of Conflans, who escaped to the shore on a spar. Seven of the French ships ran into the little river Vilaine, being compelled to throw their guns overboard to lighten themselves before crossing the bar. Nine escaped to the south. The small number of prizes taken gives no measure of the importance of the victory, which broke the spirit and strength of the French fleet so effectually that it did not appear at sea again during the rest of the war, i.e. until 1763.

QUICHÉ or KICHÉ, a tribe of Central American Indians of Mayan stock. They inhabited western Guatemala, where their descendants still survive. They were at the time of the conquest the most powerful of the three Mayan peoples in Guatemala, the other two being the Cakchiquel and the Zutugul. Their chronicles are said to date back to the 8th century. Their sacred book, the Popol Vuh, containing a mythological cosmogony, survives in a 17th-century manuscript written by a Christianized Guatemalan. To this tradition may be due the remarkable similarity of the Quiché creation story to that of the Old Testament. Their capital was Uatalan, near the site of the modern Santa Cruz Quiché, and was skillfully fortified. They had an elaborate system of government and religion. Records were kept in picture-writing. The Quiché were the first Indians met by Pedro de Alvarado in 1524 on his expedition into Guatemala.

See further Central America and Mexico; for the Popol Vuh see English edition by L. Spence (1906); see also Nutall, Ancient American Civilizations (Camb. Mass., 1901), and W. Bolhassert in Proc. Roy. Soc. Ltd. vol. 1892. QUICHERAT, Jules Étiéne Joseph (1814–1882), French historian and archaeologist, was of Burgundian origin. His father, a carpenter and cabinet-maker, came from Paray le Monial to Paris to support his large family; Quicherat was born there on the 13th of October 1814. He was fifteen years younger than his brother Louis, a great Latin scholar and lexicographer, who survived him. Although very poor, he was admitted to the college of Sainte-Barbe, where he received a thorough classical education. He showed his gratitude to this establishment by writing its history (Histoire de Sainte-Barbe, college, communauté, institution, 3 vols. 1860–1864). At the end of his studies he hesitated for some time before deciding what work he would follow, until Michelet put an end to his indecision by inspiring him with a taste for history. In 1835 Quicherat entered the École des Chartes; he left two years later at the head of the college. Once more inspired by the example of Michelet, who had just finished his admirable work on Joan of Arc (p.), he published the text of the two trials of Joan, adding much contemporary evidence on her heroine in his Proces de condamnation et de rehabilitation de Jeanne d'Arc (5 vols. 1834–1849), as well as half a volume of Aperçus nouveaux sur l'histoire de Jeanne d'Arc, in which it seems that the last word has been said on important points. From the 19th century he drew other inspirations. He published memoirs of the adventures of a brigand, Rodrigue de Villandrando (1844), which gradually grew into a volume (1877), full of fresh matter. He wrote full biographies of two chronicles of Louis XI, one very obscure, Jean Castel (in the Bibliothèque de l'École des Chartes, 1840), the other, Thomas Basin, bishop of Lisieux, who was, on the contrary, a remarkable politician, prelate and chronicler. Quicherat published the works of the latter, most of which were now brought out for the first time (4 vols. 1855–1856). In addition to these he wrote Fragments inédits de Georges Chastellain (1842), Lettres, mémoires et autres documents relatifs à la guerre du bien public en 1465 (1843, in vol. ii. Mélanges historiques, part of Documents inédits), &c. These works did not wholly occupy his time: in 1847 he inaugurated a course of archaeological lectures at the École des Chartes, and in 1849 he was appointed professor of diplomacy at the same college. His teaching had exceptionally good results. Although he was not eloquent and had a nasal voice, his hearers were loth to miss any of his thoughtful teaching, which was unbiased and well expressed. Of his lectures the public saw but only some articles on special subjects which were distributed in a number of reviews. Note should be made of a short treatise on La Formation française des anciens noms de lieu (1861); a mémoire De l'ogive et de l'architecture dite ogivale (1859), where he gives his theory on the use of stone arches—important for the history of religious architecture; an article on L'Age de la cathédrale de Laon (1874), in which he fixed the exact date of the birth of Gothic architecture; Histoire du costume en France (1875; 2nd ed. 1877), which was first published in the form of anonymous articles in the Magasin pittoresque, and which the author wished to retain the character of a popular work. Following the advice of his friends, he began to write out, towards the end of his life, his lectures on archaeology, but only the introductory chapters, up to the 17th century, were found among his papers. On the other hand, the pupils trained by him circulated his principles throughout France, recognizing him as the founder of national archaeology. In one point he seems to have taken a false step: with a warmth and pertinacity worthy of a better cause he maintained the identity of Caesar's Alesia with Alaise (Doubt), and he died without becoming a convert to the opinion, now universally accepted, that Alaise Sainte-Reine (Côte d'or) is the place where Vercingétorix capitulated. But even this error benefited science; some well directed excavations at Alaise brought many Roman remains to light, which were subsequently sent to enrich the museum at Besançon. After 1871, his course of lectures on diplomacy having been given up, Quicherat, still professor of archaeology, was nominated director of the École des Chartes. He filled this post with the same energy which he had shown in the many scientific commissions in which he had taken part. In 1878 he gave up his duties as professor, which then fell to the most conspicuous of his pupils, Robert de Lasteyrie. He died on the 8th of April 1888, a short time after, having corrected the proofs of Supplément aux témoignages contemporains de Jeanne d'Arc, published in the Revue historique. After his death it was decided to bring out his hitherto unpublished papers (Mélanges d'archéologie et d'histoire, vol. i., Celtic, Roman and Gallo-Roman antiquities, ed. A. Giry and Aug. Castan, 1885; vol. ii., Archéologie du moyen âge, ed. R. de Lasteyrie, 1886); among these are some important fragments of his archaeological lectures, but his Histoire de la laine, with which he was occupied for many years, is missing.

QUICHAU, a South American Indian tribe and stock, the ruling people of Peru when the Spaniards arrived. The Quichuan stock then included the Quichuas proper and the many vassal tribes of the ancient empire of Peru. To-day it numbers some three millions. The modern Quichuas average a height of 5 ft. to 5 ft. 6 in. They are of slender build, but with well proportioned muscular limbs, and are capable of enduring great fatigue. Their complexions are of a fresh olive colour, the skin very smooth and soft, beardless, hair straight and black, the nose aquiline. They are skilful farmers and herdsmen. (See PERU.)

QUICK, a word with no origin, and in early and many surviving uses, meant "living," "alive." It is common to Teutonic languages, cf. Ger. koch, lively, Du. kwik, and Dan. kvik; cf. also Dan. kvæg, cattle. The original root is seen in Skt. jvù; Lat. vivus, living, alive; Gr. φύς, life. In its original sense the chief uses are such as "the quick and the dead," of the Apostles' Creed, a "quickest" hedge, i.e. consisting of slips of living privet, thorn, &c., the "quick," i.e. the tender parts of the flesh under hard skin or particularly under the nail. The phrase "quick with child" is a conversion of a quick, i.e. living child. From the sense of having full
viv ing, living or lively qualities or movements, the word got its chief current meaning of possessing rapidity or speed of movement, mental or physical. It is thus used in the names of things which are in a constant or easily aroused condition of movement, e.g. "quicksand," loose water-logged sand, readily yielding to weight or pressure, and "quicksilver," the common name of the metal mercury (q.v.).

**QUIERZY [Kiersy], CAPITULARY OF**, a capitation of the emperor Charles the Bald, comprising a series of measures for safeguarding the administration of his realm during his second Italian expedition, as well as directions for his son Louis the Stammerer, who was entrusted with the government during his father's absence. It was promulgated on the 14th of June 877 at Quierzy-sur-Oise in France (dep. of Aisne), the site of a Carolingian royal palatium, before a great concourse of lords. In this document Charles takes elaborate precautions against Louis, whom he had every reason to distrust. He forbids him to sojourn in certain palaces and in certain forests, and compels him to swear not to despise his stepmother Richilde of her alodial lands and benefices. At the same time Charles refuses to allow Louis to nominate to the countships left vacant in the emperor's absence. In principle the honores (benefices) and the office of a deceased count must be given to his son, who would be placed provisionally in possession by Louis; the definitive investiture, however, could be conferred only by Charles. The capitulary thus served as a guarantee to the aristocracy that the general usage would be followed in the existing circumstances, and also as a means of reassuring the counts who had accompanied the emperor into Italy as to the fate of their benefices. It cannot, however, be regarded as introducing a new principle, and the old opinion that the capitulary of Quierzy was a legislative text establishing the hereditary system of feasts has been proved to be untenable. A former capitulary of Charles the Bald was promulgated at Quierzy on the 14th of February 857, and aimed especially at the repression of brigandage.

**QUIETISM, a complicated religious movement that swept through France, Italy and Spain during the 17th century. Its chief apostles were Miguel de Molinos, a Spaniard resident in Rome; Fénélon, the famous French divine, and his countrywoman, Madame Jeanne Marie Guyon. Quietism was essentially a reaction against the bureaucratic ecclesiasticism always latent within the church of Rome, though it had come more especially to the front during the struggles of the counter-Reformation. England carried through by the Jesuits. A theocrit to the orthodox pattern did not look, and would have thought it wrong to look, beyond the spiritual fare provided for him by the ecclesiastical authorities; all his relations with his Maker were conducted through the intermediacy of the Church. In the dogmatic sphere he believed whatever the Church believed, because the Church believed it; to the Church's institutions—the sacraments and the confessional—he looked for guidance in the practical affairs of life. Protestantism had tried to put an end to this state of things by sweeping away the Church altogether, but the Quietists were more tolerant than Luther. They did not wish to abolish the Church; they admitted that it was a necessary stage in the evolution of the human soul; but they insisted that it could only bring a man on to the lowest slopes of Paradise. Those who aspired to be really holy must learn to do so by that immediate and intimate and direct relations with their Maker. But how were they to do so? Like their contemporaries, the French Jansenists, and the Quakers and Anabaptists of northern Europe, the Quietists fell back on a doctrine of immediate inspiration of the individual conscience. To the many God spoke only in general terms through the Church; but to the few He made His will directly known. But how did He do so? How distinguish the voice of God from the vagaries of our own imagination? Quietism offered an easy test. The less "sense of proprietorship" a man had in his own good actions—the more they came from a source outside himself—the surer might he be that they were divine. If, on the other hand, they were the fruit of his deliberate thought and will, that was enough to show that they did not come from God, but from his sinful self. Hence the first duty of the Quietist was to be "passive." So far as was possible he must numb all his spontaneous activities of every kind; then he could fold his hands, and wait in dreamy meditation until inspiration came. And since all our activities have their root in desire, the shortest road to passivity was to suppress all desires and wishes of every kind. Thus the great object of the Quietist was to be "self or kill that cruel beast, self-conscious will." Then he would be dead to hope and fear; he would be icy indifferent to his fate, either in this world or the next. Thenceforward no human tastes or affections would stand in the way of his performing the will of God. He was, as Fénélon said, like a feather blown about by all the winds of grace. His mind was a mere tabula rasa, on which the Spirit printed any pattern that it chose. Hence arose the great Quietist doctrine of disinterested love. "The Quietists maintain," says a contemporary writer, "that Christian perfection means a love of God so absolutely free from all desire of happiness that it is indifferent to salvation. The soul is moved neither by hope nor fear, nor even by the foretaste of eternal bliss. Its only motive is to do the will and promote the glory of God. Other things are of no account: neither grace, nor merit, nor happiness, nor even perfection, in so far as it attaches to us. Nay, the soul must be ready to renounce its hopes of heaven, and the scrupulous will often feel themselves bound to do so; for in the last and fiercest trials they are invincibly persuaded of their own damnation. In this sentence of condemnation they generously acquiesce; and thenceforward, having nothing more to lose, they stand tranquil and intrepid, without fear and without remorse. This is what the Quietists call the state of holy indifference. Their soul has lost all wish for action, all sense of proprietorship in itself, and has thereby reached the summit of Christian perfection." (André, *Vie du Père Malebranche*, ed. Ingold, Paris, 1886, p. 271.)

Quietism is an outgrowth from the mysticism of the great 16th-century Spaniards, St Teresa and St John of the Cross, though it would be unfair to hold them responsible for all the utterances of their disciples. Certainly St Teresa made much of "passivity," but she only regarded it as a refuge for a few specially constituted souls; whereas the Quietists designedly brought it within the reach of everyone. In St Teresa the passivity itself was the only safeguard against the opposite extremes of the active life, and an equally easy devotion to the Church. Among the Quietists both these checks disappear, and passivity becomes the one and only test of holiness. But if passivity is all in all, there is no room for the virtues of the active life; all Quietists cherished the ancient saying that one moment's contemplation is worth a thousand years' good works. Still less room had they for the Church. It only professed to guide men to God; but those who had already found God stood in no need of a guide. Nay, they did not even stand in need of revelation. "If Christ be the way," wrote the Quietist Malaval, "let us certainly pass by Him to God, but he who is always passing never arrives at his journey's end." Such utterances go far to explain the severity with which the Roman Church tried to stamp out the later developments of Quietism. In its earlier stages, before it had crystallized into a definite doctrine and become the cause of ecclesiastical authority, it had been better tolerated. The Spanish monk, Juan Falconi, who is generally reckoned as the father of Quietism, died in the odour of sanctity in 1632; some thirty years later his fellow-countryman, Molinos, transported his doctrines to Rome, where they gained unbounded popularity with bishops and cardinals, and even with pope Innocent XI. In 1675 Molinos published the *Guida Spirituale*, the great text-book of his school. But his success soon aroused the suspicion of the Jesuits, the great champions of militant ecclesiasticism. "Passivity" accorded ill with a zealous...
The final stages of the Quietist drama were played out in France. Here Quietist ideas had long been spreading under the leadership of enthusiasts like François Malaval (1627–1719), a blind layman of Marseilles. A more romantic figure was Jeanne Marie Guyon (1648–1717), a widow of good family and remarkable personal charm, who devoted her life to missionary journeys on behalf of “passivity.” In 1688 she was tried for bringing the French order of monks, the Convent of the Mount of Olives, which was, according to the inquisition, a mystic church. The trial lasted a year, and the cloistered nun was condemned to solitary confinement, from which she escaped to Spain. After her release in 1693 she was tried again, but she was acquitted. In 1694 she was again tried for heresy, and this time she was convicted and sentenced to house arrest. She was permitted to leave France in exchange for her renunciation of heresy, and she went to the Holy See in Rome, where she was granted the grace of an audience with Pope Clement XI. She was allowed to return to France in 1710, but she was again tried for heresy in 1712, and this time she was condemned to death. She was sentenced to be burned at the stake, but she was allowed to choose between death by fire and death by fall. She chose death by fall, and she was burned alive at the stake. Her body was subsequently beheaded and her head was cut off and sent to the Holy See in Rome, where it was displayed in a glass case as a warning to all who might be tempted to commit heresy.
published (1887) his Dead Men's Rock (a romance in the vein of Stevenson's Treasure Island), and he followed this up with Troy Town (1888) and The Splendid Spur (1889). After some journalistic experience in London, mainly as a contributor to the Speaker, in 1891 he settled at Fowey in Cornwall. His later novels include The Blue Pavilions (1891), The Ship of Stars (1899), Hetty Wesley (1903), The Adventures of Harry Revel (1903), Fort Amity (1904), The Shining Ferry (1905), Sir John Constantine (1906). He published in 1896 a series of critical articles, Adventures in Criticism, and in 1898 he completed R. L. Stevenson's unfinished novel, St Ives. From his Oxford days he was known as a writer of excellent verse. With the exception of the parodies entitled Green Bays (1893), his poetic work is contained in Poems and Ballads (1896). In 1895 he published a delightful anthology from the 16th and 17th-century English lyricists, The Golden Pomp, followed in 1900 by an equally successful Oxford Book of English Verse, 1250-1900 (1900). In Cornwall he was an active worker in politics for the Liberal party. He was knighted in 1910.

QUILLOTA, a town of Chile in the province of Valparaiso, on the left bank of the Aconcagua river, 20 m. above its mouth and 26 m. E.N.E. of the city of Valparaiso. Pop. (1902 estimate) 9876. The valley is noted for its beauty, fertility, and healthfulness, and is the centre of thriving fruit and wine industries. Among its fruits is the "chirimoya" (Anona cherimolina). There are rich copper mines in the vicinity. Quillota is situated on a railway between Valparaiso and Santiago, which passes through a mountainous, semi-barren country. It is one of the oldest towns of Chile, dating from the first years of the conquest.

QUILON, a seaport of India, on the Malabar coast, in the state of Travancore. Pop. (1901) 15,691. Quilon enjoys great facilities of water communication, and has an active export trade in timber, coco-nuts, ginger, pepper, &c. The palace of the maharaja of Travancore stands on the bank of Quilon lake, a beautiful sheet of water. Besides being on a projecting point, Quilon is rendered still more unsafe to approach by the bank of hard ground called the Tangasseri reef, which extends some distance to the west-south-west and west of the point and along the coast to the northward. There is good anchorage, however, in a bight about 3 m. from the fort. Quilon is one of the oldest towns on the Malabar coast, and continued to be a place of considerable importance down to the beginning of the 16th century. It is now the headquarters of the Travancore army, with a subsidiary battalion. Cotton weaving and spinning and the manufacture of tiles are the chief industries. It is the terminus of a railway across the hills from Tinnevelly. Adjoining Quilon is the British village of Tangasser, formerly a Portuguese town and then a Dutch settlement, which is administered with Anjengo; pop. (1901) 1733.

QUILT, properly a coverlet for a bed, consisting of a mass of feathers, down, wool or other soft substance, surrounded by an outer covering of linen, cloth, or other material. In its earlier uses the "quilt" was made thick, and served as a form of mattress. The term was also given to a stitched wadded lining for body armour, and also, when made stout and closely padded, to a substitute for armour. The word came into English from O. Fr. couille, colle, or couette, mod. couette. This is derived from Lat. culcita or culcitra, a stuffed mattress or cushion. From the form culcita came O. Fr. coire ou coure, whence coure pointe, Low Lat. culpa pointa, i.e. stitched or quilted cushion; this was corrupted to conte pointe, Eng. counterfeit, which in turn was changed to "counterpoint," as if from Lat. ponere, piece of cloth cut out, and ponere, "to put," a coverlet for a bed, and "quilte," are by origin the same word.

QUIMPER, formerly Quimper-Corentin, a town of France, capital of the department of Finistere, 158 miles north-west of Nantes and 68 miles south-east of Brest on the railway between those towns. Pop. (1906) 16,559. The delightful valley in which it lies is surrounded by high hills and traversed by the Steir and the Odet, which, meeting above the town, form a navigable channel for vessels of 150 tons to the sea (11 miles).

There is a small general shipping trade. Of the town walls (15th century) a few portions are preserved in the terrace of the episcopal palace and in the neighbourhood of the college. Quimper is the seat of a bishopric in the province of Rennes. The cathedral, dedicated to St Corentin and erected between 1239 and 1515, has a fine façade (c. 1425), the pediment of which is crowned by a modern equestrian statue of King Grallon, and adorned (like several other external parts of the building) with heraldic devices in granite. Two lateral towers with modern spires (1854-56) and turrets reach a height of 247 feet. The axis of the choir is deflected towards the north, a feature not uncommon, but here exaggerated. The nave and the transept are in the style of the 15th century, and the central boss bears the arms of Anne of Brittany (1476-1514). The terminal chapel of the apse dates from the 13th century. In the side chapels are the tombs of several early bishops. The high altar, tabernacle, and chalices are costly works of contemporary art. The pulpit panels represent episodes in the life of St Corentin. Of the other churches may be mentioned the church of Locmaria, dating from the 11th century, and the chapel of the 15th century connected with the episcopal palace. A number of houses, in wood or stone, date from the 15th, 16th and 17th centuries. The museum, built in 1860-70, contains archaeological collections and about 1300 paintings and drawings. In 1868 a bronze statue of Laennec the inventor of the stethoscope (born at Quimper in 1781) was erected in Place St Corentin.

Quimper, or at least its suburb Locmari, which lies below the town on the left bank of the Odet, was occupied in the time of the Romans, and traces of the ancient foundations exist. Later Quimper became the capital of Cornouailles and the residence of its kings or hereditary counts. It is said to have been granted to the town by the bishop of Cornouailles from Great Britain and founded the bishopric which was first held by St Corentin about 495. Hoel, count of Cornouailles, marrying the sister and heiress of Duke Conan in 666, united the countship with the duchy of Brittany. Quimper suffered in the local wars of succession. In 1344 it was sacked by Charles of Blois. Monfort failed in his attempt to take the town by storm on August 11, 1354, but it opened its gates to his son John IV, in 1364 after the victory at Auray. At a later period it sided with the League. Doubtless on account of its distance from the capital, Quimper, like Carpentras and Landerneau, has been a frequent butt of French popular wit.

QUIMPERLE, a town of western France, capital of an arrondissement in the department of Finistère, at the confluence of two rivers which unite to form the Laïer, 28 m. E.S.E. of Quimper by rail. Pop. (1906) town 6203, commune 9176. Quimperlé grew up round the abbey of Ste Croix, founded in the 11th century, the romanesque basilica of which, restored in modern times, still remains. The church of St Michel (14th and 15th centuries), with a fine tower, crowns the hill above the town. Quimperlé has a tribunal of first instance, and carries on the manufacture of farm implements, railway material, paper, &c., and trades in grain, timber, cattle and agricultural products. The town has a small port.

QUIN, JAMES (1603-1766), English actor of Irish descent, was born in London on the 24th of February 1603. He was educated at Dublin, and probably spent a short time at Trinity College. Soon after his father's death in 1710, he made his first appearance on the stage at Abel in Sir Robert Howard's The Committee at the Smock Alley Theatre. Quin's first London engagement was in small parts at Drury Lane, and he secured the part of Claudio in Much Ado About Nothing; he also sang the role of Fidelio in the opera, on the 8th of November 1715. The next year he appeared as Hotspur at Lincoln's Inn, where he remained for fourteen years. On the 10th of July 1718 he was convicted of manslaughter for having killed Bowen, another actor, in a duel which the victim had himself provoked. Quin was not severely punished, the affair being regarded as more of an accident than a crime. The public took a similar view of another episode in which Quin, on being attacked by a young actor who had been angered by the sarcastic criticism of his superior,
drew upon him and killed him. But if he was eager in his own defence he was no less so in that of others. In 1721 a drunken nobleman reeled on to the stage of the theatre and assaulted the manager, Rich, whose life was saved by Quin's prompt armed interference. This resulted in a riot, and thereafter a guard was stationed in all theatres. In 1732 Quin appeared at Covent Garden, returning to Drury Lane from 1733 to 1741, and in 1742 was again at Covent Garden, where he remained until the close of his career. On the 14th of November 1746 Quin played Horatio and Garrick Lothario to the Calista of Mrs Cibber in Rose's *Fair Penitent*. The applause of the audience was so great as to disconcert if not actually to alarm the two actors. Public interest was yet more keenly stimulated in comparing Garrick's and Quin's impersonations of Richard III, the popular verdict being loudly in favour of Garrick. But Quin's Falstaff in King Henry IV was emphatically preferred to the Hotspur of his rival. In consequence of an attempt made by Garrick in 1750-51 to draw him away from Covent Garden, Quin was enabled to extort from his manager a salary of £1000 a year, the highest figure then reached in the profession. Quin's last regular appearance was on the 15th of May 1757, as Horatio in the *Fair Penitent*, though in the following year he twice played Falstaff for the benefit of friends. He had retired to Bath, where he lived a happy life, with late hours and much eating and drinking, until his death on the 21st of January 1766. He was buried in the abbey church at Bath. Some coolness which had arisen between Quin and Garrick before the former's retirement was dissipated on their subsequent meeting at Chatsworth at the duke of Devonshire's, and Quin paid many a visit to Garrick's villa at Hampton in the latter part of his life. The epitaph in verse on his tomb was written by Garrick. Quin's well displayed a generous nature, and among numerous bequests was one of fifty pounds to "Mr Thomas Gainsborough, limmer."

In the Garrick Club in London are two portraits of the actor ascribed to Hogarth, and a portrait by Gainsborough is in Buckingham Palace. His personality was not gracious. His jokes were coarse; his temper irascible; his love of food, his important airs, and his capacity for deep drinking do not command respect; on the other hand, a few of his jokes were excellent, and there was no rancour in him. On many occasions he showed his willingness to help persons in distress. His character is summarized by Smollett in *Humphrey Clinker*. As an actor his manner was charged with an excess of gravity and deliberation; his pauses were so portentous as in some situations to appear even ludicrous; but he was well fitted for the delivery of Milton's poetry, and for the portrayal of the grave roles in his repertory.

See The Life of Mr. James Quin, Comedian, published in 1766 and reprinted in 1887.

**QUINNAULT, PHILIPPE** (1653-1688), French dramatist and librettist, was born in Paris on the 3rd of June 1653. He was educated by the liberality of Tristan l'Hermite, the author of *Marianne*. Quinault's first play was produced at the Hôtel de Bourgogne in 1653, when he was only eighteen. The piece succeeded, and Quinault followed it up, but he also read for the bar; and in 1660, when he married a widow with money, he bought himself a place in the Cour des Comptes. Then he tried comedies (*Agrippa, &c.*) with more success than desert. He received one of the literary pensions then recently established, and was elected to the Academy in 1670. Up to this time he had written some sixteen or seventeen comedies, tragedies, and operas, of which the tragedies were mostly of very small value and the tragi-comedies of little value. But his comedies—especially his first piece *Les Rivas* (1653), *L'Amanant indiscert* (1654), which has some likeness to Mollière's *Etourdi*, *Le Fantôme amoureux* (1659), and *La Mère coquette* (1665), perhaps the best—are much better. But in 1671 he contributed to the singular miscellany of *Psyché*, in which Corneille and Mollière also had a hand, and which was set to the music of Lully. Here he showed a remarkable faculty for lyrical drama, and from this time till just before his death he confined himself to composing libretti for Lully's work. This was not only very profitable (for he is said to have received four thousand livres for each, which was much more than was usually paid even for tragedy), but it established Quinault's reputation as the master of a new style,—so that even Boileau, who had previously satirized his dramatic work, was converted, less to the opera, which he did not like, than to Quinault's remarkably ingenious and artist-like work in it. His libretti are among the very few which are readable without the music, and which are yet carefully adapted to it. They certainly do not contain very exalted poetry or very perfect drama. But they are quite free from the ludicrous doggerel which has made the name libretto a byword, and they have quite enough dramatic merit to carry the reader, much more the spectator, along with them. It is not an exaggeration to say that Quinault, coming at the exact time when opera became fashionable out of Italy, had very much to do in establishing it. His first piece after *Psyché* was a kind of classical masque. *Les Fêtes de l'Amour et de Bacchus* (1672). Then came *Codman* (1674), *Acleste* (1674), *Thésée* (1675), *Alcyon* (1676), one of his best pieces, and *Isis* (1677). All these were classical in subject, and so was *Proserpine* (1680), which was superior to any of them. *The Triumph of Love* (1681) is a mere ballet, but in *Perseé* (1682) and *Phaeton* (1683) Quinault returned to the classical opera. Then he finally deserted it for romantic subjects, in which he was even more successful. *Amadis de Gaulle* (1684), *Roland* (1685), and *Armide* (1686) are his masterpieces, the last being the most famous and the best of all. The very artificiality of the French lyric of the later 17th century, and its resemblance to alexandrines cut into lengths, were aids to Quinault in arranging lyrical dialogue. Lully died in 1687, and Quinault, his occupation gone, became devout, and began a poem called the "ASH-TRUCK OF HERESY." He died on the 28th of November 1688.

The best edition of his works is that of 1739 (Paris, 5 vols).

**QUINAZOLINES** (Phenazines or benzopyrimidines), in organic chemistry, heterocyclic compounds of the structure shown in the inset formula. They may be regarded as resulting from the fusion of a benzene with a pyrimidine nucleus in the 5.6 position. They are isomeric with the cinolines, phthalazines and quinoxalines. They may be obtained by the action of alcoholic ammonia on the acylid derivatives of orthoaminobenzaldehydes and ortho-aminoketones (A. Bischler, Ber., 1891-93): C₆H₅CHO + NH₃ = C₆H₅CH₂NH = CH₂ + 2 H₂O; N.CO.R

and from the corresponding dihydro compounds on oxidation with potassium permanganate. They are stable, tertiary bases, and may be distilled without decomposition; they form addition products with alkyl iodides and double salts with mercuric and platinum chlorides. On reduction with sodium in presence of alcohol they yield dihydro derivatives. Those in which the CH group adjacent to the benzene nucleus is unsubstituted are oxidized by chromic acid to ketodihydroquinazolines (quinazoliones).

Quinoazoline (C₄H₄N₃) is obtained by oxidizing its dihydro-derivative with potassium ferricyanide. The dihydro derivatives exist in three different stereoisomeric forms, the addition of hydrogen in the diazone ring can take place in three different positions, namely, in the 3,4, 1,4 and 1,2 positions, and these different types are distinguished by the symbols Δ1, Δ2, Δ3, denoting that the double linkage is between the first and second, second and third, and third and fourth atoms in the diazine ring. The Δ1 series, which are obtained by the elimination of the elements of water from the acylid derivatives of ortho-aminobenzaldehydes, are rather strong bases which can yield stable salts and which correspond to the corresponding keto derivatives on oxidation (C. Paal, Ber., 1889-1896). 4-Keto-dihydroquinazoline (2-quinazoline) is formed by oxidizing the dihydro base with potassium permanganate; by boiling solution of quinoazoline with water it yields 4, prok. Chem., 1885, (2) 31 p. 124; or by heating anthrancic acid with formaldehyde (S. Niemontowski, Ber., 1865, 28, p. 443). It reacts both in the enol and keto forms, yielding both N-ethers and O-ethers, the former being more frequent. The Δ2 series is obtained by heating acetyl-orthobenzaldehydes with zinc chloride, whilst the Δ3 series, which
is only known in the form of its keto derivatives (α-quinazolines), results from the fusion of urea with ortho-aminobenzaldehydes and benzophenones, the elements of water and of ammonia being eliminated (G. Gabriel and Th. Posner, Ber., 1895, 28, p. 1037). They possess feeble basic and phenolic-ortho-derivatives. The keto-quinazolines are obtained by reducing the quinazolines and dihydroquinazolines and by condensing ortho-aminobenzaldehyde with aldehyde (M. Busch, Jena. prak., Chem., 1864, 2 (2), 55, p. 414). The ring CH₃CHOH is then polymerized in growing to CH₃-C₆H₄-C₊H₅-CHO, which contains an unknown base. The keto derivatives of this series result by the action of carbonyl chloride on ortho-aminobenzaldehydes of the type H₂NCH₂CH₃NH⁺ (M. Busch, Ber., 1892, 25, p. 2835), or from the ammonium salt. The basic precursors are obtained by reducing the keto-compounds with H₂, which is decomposed into H₂O and CO₂. The keto-ammonium salts are decomposed by the action of H₂ on the keto-compounds with HCl, which is decomposed into H₂O and CO₂.

The keto-quinazolines are obtained by reducing the quinazolines and dihydroquinazolines and by condensing ortho-aminobenzaldehyde with aldehyde (M. Busch, Jena. prak., Chem., 1864, 2 (2), 55, p. 414). The ring CH₃CHOH is then polymerized in growing to CH₃-C₆H₄-C₊H₅-CHO, which contains an unknown base. The keto derivatives of this series result by the action of carbonyl chloride on ortho-aminobenzaldehydes of the type H₂NCH₂CH₃NH⁺ (M. Busch, Ber., 1892, 25, p. 2835), or from the ammonium salt. The basic precursors are obtained by reducing the keto-compounds with H₂, which is decomposed into H₂O and CO₂. The keto-ammonium salts are decomposed by the action of H₂ on the keto-compounds with HCl, which is decomposed into H₂O and CO₂.

The common Japanese quince, Pyrus or Cydonia japonica, is grown in gardens for the sake of its flowers, which vary in colour from creamy white to rich red, and are produced during the winter and early spring months. The fruit is green and fragrant but quite unpalatable. C. Matuei, a more recently introduced shrub from Japan, bears a profusion of equally beautiful orange-red flowers, which are followed by a yellow, mildly agreeable fragrance, so that, when cooked with sugar, it forms an agreeable conserve, as in the case of the ordinary quince.

**QUINCE—QUINCY, J.**

(1744–1775), American patriot, son of Josiah Quincy (1709–1784), was born in Boston on the 23rd of February 1744. He was a descendant of Edmund Quincy, who emigrated to Massachusetts in 1633, and received in 1636 a grant of land at Mount Wollaston, or Merry Mount, afterwards a part of Braintree and now Quincy. He graduated at Harvard in 1763, and studied law in the office of Ozenbridge Thacher (d. 1763), to whose large practice he succeeded. In 1767 Quincy contributed to the Boston Gazette two bold papers, signed “Hyperion,” declaiming against British oppression; they were followed by a third in September 1768; and on the 12th of February 1770 he published in the Gazette a call to his countrymen to break off all social intercourse “with those whose commerce contaminates, whose luxuries poison, whose avarice is insatiable, and whose unnatural oppressions are not to be borne.” After the “Boston massacre” (4th of March 1770) he and John Adams defended Captain Preston and the accused soldiers and secured their acquittal. He used the signatures “Mentor,” “Callisthenes,” “Marchmont Needham,” “Edward Sexby,” &c., in later letters to the Boston Gazette. He travelled for his health in the South in 1773, and left in his journal an interesting account of his travels and of society in South Carolina; this journey is important in that it brought the young patriots in closer relations with the Federalist leaders in Massachusetts. In May 1774 he published Observations on the Act of Parliament, commonly called “The Boston Port Bill,” with Thoughts on Civil Society and Standing Armies, in which he urged “patriots and heroes” to “form a compact for opposition—a band for vengeance.” In September 1774 he left for England, where he consulted with leading Whigs as to the political situation in America; on the 16th of March 1775 he started back, but he died on the 26th of April in sight of land.

See the Memoir of the Life of Josiah Quincy, Jun., of Massachusetts (Boston, 1825; 2nd ed., 1874), by his son, which contains his more important papers.

His son, Josiah Quincy (1772–1864), American lawyer and author, was born in Boston on the 4th of February 1772. He studied at Phillips Academy, Andover, graduated at Harvard in 1790, studied law, and was admitted to the bar in 1793, but was never a prominent advocate. He became a leader of the Federalist party in Massachusetts; was an unsuccessful candidate for the national House of Representatives in 1800; served in the Massachusetts Senate in 1804–5; and was a member in 1805–13 of the national House of Representatives, where he was one of the small Federalist minority. He attempted to secure the exemption of fishing vessels from the Embargo Act, urged the strengthening of the American navy, and vigorously opposed the erection of Orleans Territory (Louisiana) into a state in 1811, and stated that he “deliberate opinion, that if this bill passes, the bonds of this Union are virtually dissolved; that the States that compose it are free; and that they have no obligations to maintain it; and that, as it will be the right of all, so it will be the duty of some to prepare definitely for a separation,—amicably if they can, violently if they must.” This is probably “the first assertion of the right of secession on the floor of Congress.” Quincy left Congress because he saw that the Federalist opposition was useless, and thereafter was a member of the Massachusetts Senate until 1820; in 1821–22 he was a member and speaker of the House of Representatives, from which he resigned to become judge of the municipal court of Boston. In 1823–28 he was mayor of Boston, and in his term Faneuil Hall Market House was
QUINCY

built, the fire and police departments were reorganized, and the city's care of the poor was systematized. In 1829-1834 he was president of Harvard College, of which he had been an overseer since 1810, when the board was reorganized; he had been called "the great organizer of the university"; he gave an elective (or "voluntary") system an elaborate trial; introduced a system of marking (on the scale of 8) on which college rank and honors, formerly rather carelessly assigned, were based; first used courts of law to punish students who destroyed or injured college property; and helped to reform the finances of the university. During his term Dane Hall (for law) was dedicated, Gore Hall was built, and the Astronomical Observatory was equipped. His last years were spent principally on his farm in Quincy, where he died on the 1st of July 1864.

He wrote a Memoir of his father (1825): a History of Harvard University (2 vols. 1849), marred by a tendency to belittle the clerical régime; The Journals of Major Samuel Shaw (1847); The History of the Boston Athenæum (1851); The Municipal History of the Town and City of Boston (1852); A Memoir of the Life of J. Q. Adams (1858); and Essays on the Sealing of Cattle (1859), only one of his many practical contributions to agriculture. See Edmund Quincy, Life of Josiah Quincy (Boston, 1867).

Josiah Quincy (1802-1882), son of the last-named, was mayor of Boston in 1845-1849, and author of Figures of the Past (1882); his brother Edmund (1808-1877) was a prominent Abolitionist, and author of the biography of his father and of a romance, Wensley (1854); and his sister Eliza Susan (1798-1884) was her father's secretary and the biographer of her mother. Josiah Quincy (1802-1882) had two sons—Josiah Phillips (1829-1910), a lawyer, who wrote, besides some verse, The Protection of Majorities (1876) and Double Taxation in Massachusetts (1889); and Samuel Miller (1833-1887), who practised law, wrote on legal subjects, served in the Union army during the Civil War, and was brevetted brigadier-general in 1865. Josiah Quincy (b. 1859), a son of Josiah Phillips Quincy, was prominent in the Democratic party in Massachusetts, and was mayor of Boston in 1865-1869 and 1870-1874. Quincy, a city and the county-seat of Adams county, Illinois, U.S.A., in the western part of the state, on the Mississippi river, about 105 m. W. of Springfield. Pop. (1890) 31,494; (1900) 36,252, of whom 4961 were foreign-born—3088 being of German birth—and 2029 were negroes; (1910 census) 36,587; Land area (1906) 5,8 sq. m. Quincy is served by the Chicago, Burlington & Quincy, the Quincy, Omaha & Kansas City, and the Wabash railways, and by lines of river steamers, which find an excellent harbour in Quincy Bay, an arm of the Mississippi. The city is built on the river bluffs, which command an extensive view. In Indian Mounds park, within the city limits and owned by the city, are prehistoric mounds. The Quincy Library, founded in 1837, has been a free public library since 1889. Among the principal public buildings are the Courthouse and the Federal Government building. The State Soldiers' and Sailors' Home (1857), with grounds covering 222 acres, is in Quincy; one of its fifty-five buildings (Lippincott Memorial Hall) was erected by the veterans of the institution in memory of Charles E. Lippincott, the first superintendent. There is a monument in Quincy in memory of George Rogers Clark, and the homestead (built in 1835) of John Wood, founder of the city, is now owned by the Quincy Historical Society, organized in 1896. Quincy is the seat of St Francis Solanus College (1860) and St Mary's Institute (Roman Catholic); The Chaddocks Boys' School (Methodist Episcopal), until 1900 known as Chaddock College; two schools of music; and the Gen City Business College. Among the charitable institutions are Blessing Hospital (1875), St Mary's Hospital (1867; in charge of the Sisters of St Francis), the Woodland Home for Orphans and Friendless (1853), St Aloysius Orphans' Home (1856), and several homes for the aged and infirm. The city is the seat of a Protestant Episcopal bishop. Quincy is the industrial and commercial centre of a large region. The value of factory products in 1905 was $10,748,224, an increase of 35.7 per cent. since 1900. Among the manufactures are stoves and furnaces, foundry and machine shop products, carriages and wagons, flour and grist mill products, malt liquors, dairymen's and poulterers' supplies, show-cases, men's clothing, agricultural implements, saddlery and harness, and lumber.

In 1822 John Wood (1798-1880), the first white settler, built a log cabin here, and in 1825, Quincy, then having less than ten inhabitants, was made the county-seat of Adams county, both town and county being named through Wood's influence in honour of John Quincy Adams. Wood was lieutenant-governor of the state in 1857-1860, and acting-governor in 1860-1861. A bronze statue (dedicated in 1883) in his memory stands in Washington Park. There was a general hospital of the United States Army in Quincy during the Civil War. Quincy was incorporated as a town in 1834, and was chartered as a city in 1839.

QUINCY, a city of Norfolk county, Massachusetts, situated on Massachusetts Bay, and separated from Boston by the Neponset river on the N. and from Weymouth by Fore river on the S. Pop. (1850) 26,723; (1900) 23,896, of whom 9662 were foreign-born; 22,642; and about 16 sq. m. It is served by the New York, New Haven & Hartford railway, and by an interurban electric line. To a large degree Quincy is a residential suburb of Boston. The birthplaces of John Adams, built in 1681, and of John Quincy Adams, built in 1716, are still standing. The Stone Temple, or First (Unitarian) Congregational Church, is the burial-place of the two Adamses. Quincy was also the home of Charles Francis Adams. John Adams gave to the town his valuable private library, and in 1822 founded here the Adams Academy for boys (now closed). In the home of Josiah Quincy (1802-1882) in Wollaston Park is the Quincy Mansion School for Girls. Woodward Institute (1894) is an endowed high school for girls. The public school system, the "Quincy System," was made famous in 1875-1880 by Col. Francis Wayland Parker (1837-1902), who abolished learning lessons by rote, and introduced Froebelian principles. A public library was opened in 1878 and in 1883 it was housed in the Crane Memorial Hall, designed by H. H. Richardson, and given by the family of Thomas Crane (1803-1875), who had spent his early youth in the town, but had lived in New York City from 1827 until his death. The library contained about 26,000 volumes in 1908. The city has a fine system of parks, among them being Merrymount and Faxon, the latter named in honour of the family of Henry H. Faxon, who in 1882 secured a negative vote by the town to the question whether "licenses be granted for the sale of intoxicating liquors," subsequently there has been a similar vote each year. The manufactures of Quincy were long unimportant, with the exception of "Quincy granite," which was first quarried in 1835—this being the first "systematic siliceous crystalline rock quarrying" in New England—and of which the output in the form of tombstones and monuments in 1905 was valued at $2,018,198, and in the form of "marble and stone work" was valued at $36,924. But manufacturing was rapidly increasing. In 1915 in this period the value of factory products increased 198.2 per cent., to $5,982,446, and the capital invested increased 389%, to $9,220,870. Quincy granite, a hornblende, pyroxene, bluish or greyish, without mica, was used for the construction of the Bunker Hill monument at Charlestown (in 1826), and of King's Chapel, Boston; and for interior decorations it has found some use, for example in the Philadelphia city buildings. Engines, and iron and steel ships are built at a shipyard on the Fore river, and tubular rivets and studs, gearing, foundry products, and translucent fabrics are among the city's other products.

1 Since 1877 the Granite Cutters' Journal has been published here by the Granite Cutters' International Association of America. For a description of the granite quarried in the vicinity of Quincy, see T. N. Dale, The Chief Commercial Granites of Mass., New Hampshire and Rhode Island (Washington, 1908), Bulletin 354 of the U.S. Geol. Survey.

2 Here were built various vessels of the U.S. Navy, including the battleship "North Dakota."
The site of the present city was settled in 1625 as Merry Mount or Mount Wollaston by Thomas Morton (q.v.)—the present Wollaston Heights is a part of the grant of 600 acres made in 1636 by the town of Boston to William Hutchinson, husband of Anne, the Antinomian, and who was formerly known as Taylor's Hill. A Puritan settlement was made here in 1634. This first settled part of Braintree (q.e.)—a name given in 1640 to the community then organized—after 1708 was officially called the North Precinct of the Town of Braintree; here the Adamses and the Hancocks lived, and Quincy was the birthplace of John Hancock—in a house on Hancock lot lived the first Josiah Quincy; the Mount Wollaston farm was a legacy to John Quincy (1689-1767), in whose honour the township was named on its separation from the township of Braintree in 1792, and whose name was borne by his great grandson, John Quincy Adams. In 1829 a railway about 4 m. long to the Neponset valley was built here—the first in New England—for carrying granite from the quarries to tide-water; the cars were drawn by horses. The township had previously been engaged in maritime pursuits, agriculture, and the manufacture of leather. Township government, owing to the abolition of the committee on general business and the consequent confusion of handling so many and minute details, and to the addition to the population of a large Irish element and a large New Hampshire element, both workmen in the quarries, reached the minimum of efficiency in 1840-1870; in 1870, however, the town-meetings were reformed, and in 1874 a committee to consider business details was again appointed. In 1888 Quincy was chartered as a city.

See “A Study of Church and Town Government,” by C. F. Adams, in the second volume of his Three Epistles of Massachusetts History, for an elaborate history of the community, with his Centennial Milestone, An Address in Commemoration of the One Hundredth Anniversary of the Incorporation of Quincy, Mass. (Cambridge, Massachusetts, 1892); D. M. Wilson, Quincy, Old Braintree and Mount Wollaston (Boston, 1900); and Where American Independence Began (Boston, 1902); and D. M. Wilson and C. F. Adams, Col. John Quincy of Mount Wollaston, 1665-1707 (Quincy, 1909), published by the Quincy Historical Society, and containing J. F. Mathew's record of the celebration in February 1808 in honour of Col. Quincy; and W. S. Pattee, History of Old Braintree and Quincy (Quincy, 1878).

QUINET, EDGAR (1803-1875), French historian and man of letters, was born at Bourg-en-Bresse, in the department of the Ain, France, on the 17th of February 1803. His father, Jerome Quinet, had been a commissary in the army, but being a strong republican and dissatisfied with Napoleon's usurpation, he gave up his post and devoted himself to scientific and mathematical study. Edgar, who was an only child, was much alone, but his mother (Eugénie Rozat Lagis, who was a person of education and strong though somewhat unorthodox religious views) exercised great influence over him. He was sent to school first at Bourg and then at Lyons. His father wished him on leaving school to go into the army, and then suggested business. But Quinet was determined upon literature, and after a time got his way. His first publication, the Tableaux du juin errant, appeared in 1823. Being struck with Herder's Philosophie der Geschichte, he undertook to translate it, learnt German for the purpose, published his work in 1827, and obtained by it considerable credit. At this time he was introduced to Cousin, and made the acquaintance of Michelet. He had visited Germany and England before the appearance of his book. Cousin procured him a post on a government mission to the Morea in 1829, and on his return he published in 1830 a book on La Grèce moderne. Some hopes of employment which he had after the revolution of February were frustrated by the reputation of speculative republicanism which he had acquired. But he joined the staff of the Revue des deux mondes, and for some years contributed to it numerous essays, the most remarkable of which was that on Les Épopées françaises du XIIème siècle, an early, though not by any means the earliest, appreciation of the long-neglected chansons de geste. Ahàsòvérs, his first original work of consequence, appeared in 1833. This is a singular prose poem, in language sometimes rather bombastic but often beautiful. Shortly afterwards he married Minna Moré, a German girl with whom he had fallen in love some years before. Then he visited Italy, and, besides writing many essays, produced two poems, Napoleon (1835) and Prométhée (1838), which being written in verse (of which he was not a master) are inferior to Ahàsòvérs. In 1838 he published a vigorous reply to Strauss's Leben Jesu, and in that year he received the Legion of Honour. In 1839 he was appointed professor of foreign literature at Lyons, where he began the brilliant course of lectures afterwards embodied in the Génie des religions. Two years later he was transferred to the Collège de France, and the Génie des religions itself appeared (1842).

Quinet's Parisian professorship was more notorious than fortunate, owing, it must be said, to his own fault. His chair was one of Southern Literature, but, neglecting his proper subject, he chose, in conjunction with Michelet, to engage in a violent polemic with the Jesuits and with Ultramontanism. Two books bearing exactly these titles appeared in 1843 and 1844, and contained, as was usual with Quinet, the substance of his lectures. These excited so much disturbance, and the author so obstinately refused to confine himself to literature proper, that in 1846 the government put an end to them—a course which was not disapproved by the majority of his colleagues. By this time Quinet was a pronounced republican, and something of a revolutionist. He appeared in arms during the disturbances which overthrew Louis Philippe, and was elected by the department of the Ain to the Constituent and then to the Legislative Assembly, where he figured among the extreme radical party. He had published in 1848 Les Révolutions d'Italie, one of his principal though not one of his best works. He wrote numerous pamphlets during the short-lived Second Republic, attacked the Roman expedition with all his strength, and was from the first an uncompromising opponent of Prince Louis Napoleon. He had already appeared in 1839 in the volume of his Histoire des débuts politiques de Louis Napoleon (1839), and published a book of the class of Ahàsòvérs and Merlin, but even vaguer, dealing not with history, legend, or philosophy, but with physical science for the most part.

Quinet had refused to return to France to join the liberal opposition against Napoleon III., but immediately after Sedan he returned. He was then restored to his professorship, and during the siege wrote vehemently against the Germans. He was elected deputy by the department of the Seine in 1871, and was one of the most obstinate opponents of the terms of peace between France and Germany. He continued to write till his death, which occurred at Versailles on the 27th of March 1875. Le Siège de Paris et la défense nationale appeared in 1871, La République in 1872, Le Livre de l'exilé in the year of its author's death and after it. This was followed by three volumes of letters and some other work. Quinet had already in 1838 published a pamphlet which he called Histoire de mes idées.

Quinet's character was extremely amiable, and his letters to his mother, his accounts of his early life, and so forth, are likely always to make him interesting. He was also a man of great moral conscientiousness, and as far as intention went perfectly disinterested. As a writer, his chief fault is want of concentration;
as a thinker and politician, vagueness and want of practical determination. His historical and philosophical works, though showing him reading, fertile thought, abundant facility of expression, and occasionally, where prejudice does not come in, acute judgment, are rather (as not a few of them were in fact) reported lectures than formal treatises. His rhetorical power was altogether superior to his logical power, and the natural consequence is that his work is full of contradictions. These contradictions were, moreover, due not merely to an incapacity or an unwillingness to argue strictly, but also to the presence in his mind of a large number of inconsistent tastes and prejudices which he either could not or would not co-ordinate into an intelligible creed. Thus he has the strongest attraction for the picturesque side of medievalism and catholicism, the strongest repulsion for the restrictions which medieval and Catholic institutions imposed on individual liberty. He refused to submit himself to any form of positive orthodoxy, yet when a man like Strauss pushed unorthodoxy to its extreme limits Quinet revolted. As a politician he acted with the extreme radicals, yet universal suffrage disgusted him as unreasonably in its principle and dangerous in its results. His pervading characteristic, therefore, is that of inconsistency, yet the speculative and moralist, but as deficient in coercive force of matter as it is in lasting precision and elegance of form. He is less inaccurate in fact than Michelet, but he is also much less absorbed by a single idea at a time, and the result is that he seldom attains to the vivid representation of which Michelet was a master.

Bibliography.—His numerous works appeared in a uniform edition of twenty-eight volumes (1877–79). His second wife, in 1870, published certain Mémoires d’exil, and Lettres d’exil followed in 1873. In that year Prof. George Saintsbury published a selection of the Lettres à sa mère with an introduction. For many years Quinet received little attention in France, but it was revived, though not very strongly, by the publication in 1899 of Madame Quinet’s Cinquante ans, and in 1891 by the centenary of his birth. On this latter (1903) appeared A l’occasion du centenaire, by E. Ledrain; see also Libres Penseurs religieux, by E. Paris (1905). There is in English an elaborate Early Life and Writings of Edgar Quinet, by G. Heath (London, 1881).

**QUININE**, the most important alkaloid contained in cinchona bark (see **Cinchona**). In 1810 Gomez of Lisbon obtained a mixture of alkaloids which he called quina, consisting of an astringent extract of the bark with water and then adding a solution of caustic potash. In 1820 Pelletier and Cavennou proved that the quinidine of Gomez contained two alkaloids, which they named quinine and cinchonine. Later quinidine and cinchonine were discovered, and subsequently several other alkaloids, but in smaller quantity.

**Chemistry.**—The alkaloids exist in the bark chiefly in combination with cinchotannic and quinic acids. The cinchotannic acid apparently becomes altered by atmospheric oxidation into a red-colouring matter, known as cinchona-fulvic or cinchona red, which is very abundant in some species, as in C. succirubra. For this reason those barks which, like C. Calisaya, C. officinalis, and C. Ledgeriana, contain but little colouring matter are preferred, the quinine being more easily extracted from them in a colourless form. The exact mode of extraction adopted by manufacturers is secret. That hitherto adopted by the Indian Government for the preparation of the cinchona febrifuge (see below) is simple, but the whole of the alkaloid present in the bark is not obtained by it. This method is to exhaust the powdered bark with water, acetylated with hydrochloric acid, and then to precipitate the alkaloids by caustic soda. Another method consists in mixing the powdered bark with milk of lime, drying the mass slowly with frequent stirring, exhausting the powder with boiling alcohol, removing the excess of alcohol by distillation, adding sufficient dilute sulphuric acid to dissolve the alkaloid and throw down colouring matter and traces of lime, &c, filtering, and allowing the neutralized liquid to deposit crystals. The sulphates of the alkaloids thus obtained are not equally soluble in water, and the quinine sulphate can be separated by fractional crystallization, being less soluble in water than the other sulphates.

Quinine of commerce is the neutral salt, \( \text{C}_{19}\text{H}_{20}\text{N}_2\text{O}_4\cdot\text{H}_2\text{O} \cdot \text{SO}_4\cdot\text{H}_2\text{O} \), which occurs in commerce in the form of very light slender white acicular crystals. It is soluble in about 780 parts of cold water, but in 30 of boiling water, 60 of rectified spirit (sp. gr. 0·95), and in 40 of alcohol. In sub-bases of calcium, magnesium, or sodium, but is increased by potassium nitrate, ammonium chloride, and most acids. It is not soluble in fixed oils or in ether, although the pure alkaloid is soluble in both.

In a stoichiometric solution of potassium cupreine, it is generally rendered more soluble in water by the addition of dilute sulphuric acid or of citric acid, one drop of the former or 3ths of a grain of the latter being used for each grain of the quinine sulphate. It is said, however, that free solutions of cinchonine and even those of sulphuric acid or cupreine do not dissolve quinine in the manner just described.

The acid solution of quinine is transparent, especially when diluted; and it is laevorotatory. When a solution of chlorine is first added and then ammonia an emerald-green colour, due to the formation of the lewisite, is developed; this is followed by a solution containing only 1 part of quinine in 5000, or in a solution containing not more than 0·01 part if bromine be used instead of chlorine. The fluorescence is visible in an acid solution containing not more than 0·05 parts of quinine. In the process of cupreine, it is still more pronounced. In cold alcohol has been utilized for estimating quinine quantitatively.

The other alkaloids are distinguished from quinine thus: quinidine resembles quinine, but is dextrorotatory, and the iodide of quinidine contains less iodine. The quinoline, which is dextrorotatory, does not give the thallogenous test, nor fluorescence; cinchonine resembles cinchonidine in these respects, but is dextrorotatory.

Commercial sulphate of quinine frequently contains from 1 to 10% of cinchonine sulphate, owing to the use of barks containing it. The sulphate of cinchonine is more soluble than that of quinine; and, when 1 part of quinine sulphate suspected to contain it is dissolved in 300 parts of boiling water, the resulting solution is only 0·3% cupreine, whereas, if the quinoline contains 0·01 parts of cinchonine, the formation of cupreine is equal to that of quinine. Cupreine crystals out on cooling, and the cinchonine is found in the clear mother liquor, from which it can be precipitated by a solution of potassium and sodium tartrate. Samples of quinine in which cinchonine is present usually contain a smaller percentage of cupreine, the amount of which depends on the quality of the barks.

Owing to its voluminous character as much as 18% of water may remain present in apparently dry samples of sulphate of quinine. If it loses more than 14·6% of water when dried at 100°C, it contains an excessive amount of moisture. Owing to its variability in this respect and to its use in the preparation of sub-bases, it has largely replaced the sulphate in modern medicine.

Sulphate of quinine manufactured from cuprea bark (R. pedunculata) may contain from 95 to 99% of sulphate of homquinine, which is a compound differing from the sulphate of cupreine. Homquinine is decomposed on treatment with caustic soda into quinine and a new alkaloid, cupreine, in the proportion of 2 to 3. Cupreine is soluble in a solution of caustic soda (dissolving in the presence of the latter) and the latter is used to prepare a sulphate of quinine perfectly free from either homquinine or cupreine. The medicinal properties of cupreine and homquinine are of no practical importance.

The consequence of the high price of the alkaloid an attempt was made some years ago by the Government of India to manufacture from cinchona bark a cheap febrifuge which should represent the alkaloids contained in the bark and form a substitute for quinine. This attempt met with no success. Cupreine is obtained from Cinchona succirubra, which succeeds better in India than the other species in cultivation, and grows at a lower elevation, being consequently procurable in large quantities at a comparatively low price. A mixture of the cinchona alkaloids, consisting principally of cupreine, but containing a small proportion of quinine and cinchonine, is sold under the name of "quinetum" at a cheaper rate than quinine.

The chemical constitution of quinine and the allied alkaloids is more definitely established, although certain relationships are well established. Thus quinine is methoxycinchonine or methyICupreine, cupreine being an oxyquinine. These relations are shown by the formulas:—quinidine, \( \text{C}_{19}\text{H}_{20}\text{N}_2\text{O}_4\); cupreine, \( \text{C}_{15}\text{H}_{19}\text{N}_2\text{O}_4\); homquinine, \( \text{C}_{19}\text{H}_{19}\text{N}_2\text{O}_4\); oxquinine, \( \text{C}_{19}\text{H}_{19}\text{N}_2\text{O}_4\cdot\text{OH}_2\text{O}\); cupreine, \( \text{C}_{15}\text{H}_{19}\text{N}_2\text{O}_4\cdot\text{OCH}_3\text{O}\); methoxycinchonine (duckyquinine, carbolic acid), \( \text{C}_{19}\text{H}_{19}\text{N}_2\text{O}_4\cdot\text{CO}\cdot\text{H}_2\text{O}\), whilst quinine gives quinic acid, \( \text{C}_{15}\text{H}_{19}\text{N}_2\text{O}_4\cdot\text{CO}\cdot\text{H}_2\text{O}\). This permits the writing of cinchonine, for example, as \( \text{C}_{19}\text{H}_{19}\text{N}_2\text{O}_4\text{OH}\). The different formulas of the alkaloids, none of which is more correct than the other, whilst the constitution is uncertain. The subject has been especially studied by Skraup, Königs, and von Miller; Königs and von Miller have proposed formulae consisting of a cyclic ring substituted with a vinyl group; in the former that is a bridge of \( \text{CH}_2\text{C}(\text{OH})\text{H}_2\text{O}\) from the nitrogen atom to the \( \gamma \)-carbon atom, connection with the quinoline residue being made at the
HYDROXYLIC CARBON ATOM THROUGH A -CH₂ GROUP; WHILST IN THE LATTER THE PIPERIDINE RING IS SUBSTITUTED BY A METHYL GROUP IN ADDITION TO THE VINYL GROUP AND THE BRIDGE IS SIMPLY -C(OH)-, WITH WHICH CONNESSION IS MADE AS BEFORE.

MEDICINE.—The salt of quinidine is still used in medicine, and the British Pharmacopoeia has admitted two others, which are much more valuable—the hydrochloride and the acid hydrochloride. The hydrochloride, being the hydrobromide, is somewhat larger than the hydrochlorate. C₆H₅N₂O₂HCl₂H₂O resembles the sulphate in appearance, the crystals being somewhat larger. It is soluble in less than 40 parts of cold water, and in 3 parts of alcohol (95%). The doses are similar to those of the sulphate, but somewhat smaller, owing to its greater solubility. The acid hydrochloride is the most valuable of all salts of quinine. It is in its own weight of water, and is the most rapidly and completely absorbed of all the salts of this alkaloid. It occurs in a colourless crystalline powder, having the formula C₆H₅N₂O₂·2HCl·3H₂O.

The sulphate of quinine used in medicine may contain up to 3% of cinchonidine, but should be free from cinchonine, quinidine and cuprine. There are four pharmaceutical preparations. The ferro quinate is prepared by boiling a 10% solution of quininae acetate with a saturated solution of iron bicarbonate, and filtering off the precipitate which settles in 4ths of a grain of quinine in each draught, that is, in each dose. Here the quinine acts as a bitter tonic. The tinctura quininae ammoniata or "ammoniated quinine" is made by mixing 175 parts of powdered quinine sulphate with 84 parts of cold water and 2 parts of caustic ammonia (the pharmaceutical solution of ammonium), and 18 fluid oz. of a 60% solution of alcohol. The dose of ½ to 1 draught contains little more than a grain of quinine, the antipyretic action of which is negatived by its irritant property. In early stages of a bronchitis or obstruction is due to the ammonia. The small quantity of quinine it contains is conditioned by the solubility of the alkaloid, which is precipitated when this tincture is diluted with water. No particular value attaches to the pharmacopoeial preparation of the hydrochlorate. Quinine is the active principle of Cinchona leaves, which is derived from the nuclei of the leucocytes, which contain large quantities of the nucleo-proteids, of which uric acid is a decomposition product. It is therefore plain that the diminution of leucocytic movements is to be regarded as a sign of diminished metabolism within the cells.

Therapeutics.—The supreme value of quinine is as a specific antitoxin to malaria, against which it also possesses a powerful prophylactic action. It has been given three times a day for this latter purpose, and smaller doses of the much more efficacious acid hydrochloride will be found to convey even more certain immunity. In treating malaria (including quinsy) the small doses of the urinary fraction, which is largely excreted by the kidneys, have proved most efficacious in this regard. Quinine is an antihypertonic drug, which has been used in the treatment of cases of tracheitis and influenza, with some degree of activity on the part of the muscles of the wall of the stomach. This means that the appetite is strengthened, and digestion rendered more complete. In this sense alone quinine is a tonic. The hydrochloric acid of the gastric juice is stated to convert any salt of quinine into a chloride, and it seems probable that the absorption of quinine takes place directly from the stomach, for when the drug reaches the alkaline secretions of the duodenum it is precipitated, and probably none of it is thereafter absorbed. The greater part of a dose of quinine sulphate administered by the mouth may be recovered, as a rule, from the faeces, this being much greater than the amount of quinine given. The absorption of the acid hydrochloride is much more complete. Quinine hydrochloride circulates in the alkaline blood without precipitation, probably owing to the presence of carbonic acid in the blood. This may have an effect on fying the effects of quinine on the blood—i.e., of great complexity and importance. Whilst it is not a haematologic, that in does that it does not increase the number of the red blood corpuscles, it very markedly influences the stability of the corpuscles, which have often been observed to become less refractive and prussic acid, quinine interferes with oxidation, so that oxyhaemoglobin is relatively unable to give up its oxygen to the tissues, the metabolism of which is therefore greatly modified. This property is doubtless partly—though not wholly—explanatory of the arrest of parasite development in the blood-vessels and tissues, which is very markedly affected by quinine, the characteristic "amoeboid" movements of the cells being arrested. Hence quinine stops the process of *diapedesis* or emigration of the leucocytes from the blood-vessels into the tissues, and if applied to the extravascular spaces it arrests the leucocytic movements there. The explanation that this influence on the leucocytes explained the favourable action of quinine on certain inflammatory processes no longer holds, since we know that the inflammatory conditions are of microscind origin, and that the movements of the leucocytes are not objectionable, but highly desirable as a means of defence against bacteria and their products. Quinine, therefore, is not beneficial in inflammatory conditions as far as this particular property is concerned.

The action of quinine on the circulatory apparatus is not marked. It is only in very large doses that it weakens the intracardiac reflexes, and slows and weakens the pulse, and dangerously depresses the peripheral circulation. This is of course the result of increased stability of oxyhaemoglobin. Quinine was the first antipyrétic used, and after the introduction of such preparations as anti-pyrin and acetanilide it may still be said to be the safest, though it is much less powerful. The maximum dose of the sulphate is about 40 grains, and of the acid hydrochloride about 25 grains. The temperature usually begins to fall in about two hours. The influence of quinine on a malarial temperature is due to an entirely different cause. The principal effect of the higher vertebrae quinine reduces the activity of the spinal cord, but in the human species it appears to stimulate the nervous mechanism of the uterus under certain conditions, and it is therefore included under the class of *oxytocic* or *ebolic* drugs.
QUINOLINE

Cinchonism is the name applied to the congeries of toxic symptoms which follow the prolonged administration of quinine, but may appear after one small dose in certain persons. The symptoms closely resemble those of salicylism, and also, though in less degree, those of antimony poisoning. The quinine is found in the bark, which may assume various forms, especially in medicinal people. There is headache, which, with the continuance of the drug, becomes exceedingly severe, the vision and equilibrium are affected, and there is sometimes sickness and vomiting. Generally, however, all the cases where the drug has been deliberately given for its poisonous action the results are still more severe. There may be bleeding from the nose, cutaneous congestion, deafness, blindness, coma or delirium. After doses in the minims or drops the patient has been found to die. The reason of propagating the best varieties by cuttings has been adopted, except in the case of those which do not strike readily, as in C. Ledgeriana, in which the plants are grown from the shoots of felled trees.

Some years ago it was discovered that a bark imported from Colombia under the name of cuprea bark, or "hard" bark, and derived from Remijia pendunculata, Triona, and other species, was found to possess a greater proportion of quinine than the genuine one, which was made in cross-fertilization and grafting with the view of giving vigour of growth to delicate trees yielding a large amount of alkaloid or of increasing the yield in strong-growing trees affording but small quinine. The purpose, since the stock and the graft have been found to retain their respective alkaloids in the natural proportion just as if growing separately. Hydrization also is very uncertain, and a great deal of trouble and expense have been occasioned by the method of propagating the best varieties by cuttings has been adopted, except in the case of those which do not strike readily, as in C. Ledgeriana, in which the plants are grown from the shoots of felled trees.

Until 1867 English manufacturers of quinine were entirely dependent upon South America for their supplies of cinchona bark, which were obtained exclusively from uncut lines, growing chiefly in Bolivia, Peru, and Ecuador, the principal species which were used for the purpose being Cinchona Calisaya, C. odorata, C. macrophylla, var. Polon; C. Pitayensis, C. micrantha and C. lanceolata. Since the cultivation of cinchona trees was commenced in Java, India, Ceylon and Jamaica, several other species, as well as varieties and hybrids cultivated in those countries, have been used. Later, C. lanceolata, var. Calisaya, known as the calisaya of Santa Fé, was strongly recommended for cultivation, because the shoots of felled trees afford bark containing a considerable amount of quinine; C. Pitayensis has been introduced into the Indian plantations on account of yielding the valuable alkaloid quinine, as well as quinine.

The first importation from India took place in 1867, since which time the cultivated bark has arrived in Europe in constantly increasing quantities, London being the chief market. The Indian bark, as it is known, is obtained from Java, and C. Calisaya, var. Calisaya has also been cultivated extensively in Bolivia and in Tolima, United States of Columbia. In order to obtain the cultivated bark as economically as possible, experiments were made which resulted in the discovery that, if the bark were removed from the trunks in alternate strips so as not to injure the cambium, or actively growing zone, a new layer of bark was formed in one year which was richer in quinine than the original, and that by the third year the total yield exceeded that of the ordinary growth. This is known in commerce as "renewed bark." The process has been found to be most conveniently practised when the trees are eight years old, at which age also the bark separates most easily. The yield of quinine has been ascertained to increase annually until the eleventh year, at which time it seems to reach its maximum. The portion of the trunk from which the bark has been removed is sometimes protected by moss, and the new bark which forms is then distinguished by the name of "massed bark." The species which yield the largest amount of quinine are by no means those which are cultivated in the United States of Columbia; the best results are obtained from C. lancifolia. This species has been quoted in the cases where the drug has been deliberately given for its poisonous action the results are still more severe. The bark is often employed in the form of a wash or bath, and the extract has been found to be active in the treatment of certain diseases. The quinine bark contains a large amount of an alkaloid, quinine, which is readily soluble in alcohol and water, and has a pungent, bitter taste. The quinine is a yellow, pale, and red barks, a number of varieties of unequal value.

The alkaloids are contained, according to Howard, chiefly in the cellular tissue next to the fiber. A definite knowledge has as yet been obtained of the exact steps by which quinine is formed in nature in the tissues of the bark. From analyses of the leaves, bark and root, it appears that quinine is present only in small quantities in the leaves, in larger quantity in the stem bark, and in increased proportion as it approaches the root, where quinine and other alkaloids have a tendency to increase in proportion as the root bark is generally richer in alkaloids than that of the stem. The altitude at which the trees are grown seems to affect the proportion of quinine, since it has been proved that the yield of quinine in Cinchona is less when the trees are grown below 6000 ft., than at the elevation, and that cinchonine, quinidine, and resin are at the same time increased. It has also been shown by Broughton that C. Persicaria, which yields cinchonine but no quinine, grows at a height of 6000 ft., when grown at 7990 ft., the yield of quinine has been increased by 30 to 35 per cent. In the case of C. officinalis, it has been shown that the yield of quinine is increased by 30 to 35 per cent. In the case of C. officinalis, it has been shown that the yield of quinine is increased by 30 to 35 per cent. In the case of C. officinalis, it has been shown that the yield of quinine is increased by 30 to 35 per cent.
one, and its mechanism may probably be explained as follows: The glycerin is first converted into acrolein, which combines with the aniline to form acrolein-aniline, and this product is then oxidized by the nitrobenzene:

\[ \text{CH}_3\text{CHO} \rightarrow \text{CH}_3\text{COH} \]

The nitrobenzene may be replaced by arsenic acid, when the reaction proceeds much more quietly and a cleaner product is obtained (C. A. Knueppel, Ber., 1896, 29, p. 703). The Skraup reaction is a perfectly general one for primary amino-compounds; the halogen-, nitro- and oxy-anilines (aminophenols) react similarly, as do also the toluidines, naphthylamines, amino-anthracene, meta- and para-phenylene diamines, and ortho- and 

Quinoline is a colourless liquid with a smell resembling that of pyridine. It boils at 235°C and is very hygroscopic. It is a tertiary base and forms well-defined salts. It is almost insoluble in water, but dissolves readily in the common organic solvents. It may be obtained by distillation of the solutions (H. Decker (Ber., 1895, 38, p. 1144) has found that many of the ortho-substituted quinolines will not combine with methyl iodide owing to steric hindrance, but the difficulty can be overcome in most cases by using methyl sulphate and heating the reaction components to 100°C for half an hour. Nicotinic acid and chloroacetic acid have little action on quinoline, but alkaline potassium permanganate oxidizes it to carbon dioxide, ammonia, oxalic, and quinolinic acids (S. Hoogewerff and W. A. v. Dorp, Rec. Pays Bas, 1882, 1, p. 107). Bleaching powder oxidizes it to chloroborosyrl.

It is reduced by the action of zinc and ammonia to di-and tetra-hydroquinolines. A hexahydro- and a dehydroquinoline have been obtained by heating tetrahydroquinoline with hydrochloric acid and phosphorus to high temperatures (E. Bamberger, Ber., 1890, 23, p. 1158). Numerous substitution products of quinoline are known, and the positions in the molecule are generally designated in accordance with the scheme shown in the inset formula: the letters o, m, p, a, standing for ortho-, meta-, para-, and ana-

The o-quinolines possess a certain importance owing to their relationship to the alkaloids. Those with the hydroxyl group in the benzene nucleus are prepared from the aminophenols by the Skraup reaction. Only two are known containing the hydroxyl group in the pyridine nucleus, namely, carbostyril (a-quinolinol), which is formed by the reduction of ortho-anilinoquinamic acid with ammonium sulphide (L. Chiozza, Ann., 1852, 53, p. 118) or with ferric sulphate and baryta, and kynurine (o-quinolinoquinine), which is obtained by the reduction of nitroquinoline by sodium amalgam (Claus and H. Howitz, Jour. prak. chem, 1864, 158, p. 232). It is also formed by the condensation of anthranilic acid with acetamide (S. Niemesterows, Ber., 1895, 28, p. 8111). They are both volatile solids, and many form enols when heated at 199-200°C, and the latter at 52°C.

The homologues of quinoline, the most important are quinoline, lindoline, o-phenylquinoline, and flavoline. Quinolinic (a-methylquinoline) is present in coal-tar, and a similar one by condensing aniline with parahydroxy and concentrated hydrochloric acid (O. Doebner and W. v. Miller, Ber., 1881, 14, p. 2812 et seq.). The reaction is a perfectly general one, for the aniline may be replaced by other aromatic amines and the aldehyde by others, and a large number of 2-hydroquinolines or hydroisoquinolines may be prepared in this way. Quinolinic may also be obtained by condensing ortho-anilinobenzaldehyde with acetone in presence of caustic soda (P. Friedlander, loc. cit.). It is a colourless liquid, constituting 32.5% of the caustic soda, and condensing readily with aldehydes and with phthalic anhydride. Potassium permanganate oxidizes it to acetylthranilic acid, \( \text{HOCOC}(1)(\text{CH}_2\text{H})(\text{NH}-\text{COCH}_3) \), while chromic acid oxidizes it to quinolinic acid (a-quinolinic acid). Lepidocline (e-quinolinic acid) was first obtained by distilling cinchone with caustic potash. It may be prepared synthetically by condensing ortho-aminophenol with parahydroxy and caustic soda (L. Knoy, Ann., 1896, 236, p. 231) or by the action of acetyl chloride on acetylacetone (C. Beyer, Jour. prak. Chem., 1885, 140, p. 125). It may also be prepared by condensing acetylquinoline and formaldehyde, the resulting acetoethanol, \( \text{CH}_3\text{CH}(\text{CH}_3)\text{COCH}_3 \), which can be anhydride, and forms lepidocline (W. Königs and A. Mengel, Ber., 1904, 37, p. 1322). It is a colourless liquid boiling at 253°C. Chromic acid oxidizes it to quinocline (a-quinolinic acid), and further oxidation by phthalic acid yields quinoline. By oxidation with potassium permanganate it yields phthalic acid and cinchomercuric acid. Reduction of the quinoline thus obtained yields a tetrahydro derivative.

Numerous derivatives of quinoline are obtained in the decomposition of various vegetable alkaloids. Papaverine on fusion
with alkalis yields a dimethoxyisoquinoline, whilst hydroxymethylnine, hydrocotamine and the salts of cotarine may be considered as derivatives of reduced isoquinolinas (see OPIUM).

**QUINONES**, in organic chemistry, a group of compounds in which two hydrogen atoms of a benzene nucleus are replaced by two oxygen atoms. This replacement may take place either in the ortho or para positions, giving rise to orthoquinones or para-quinones; meta-quinones do not appear to have been isolated. The para or true quinones are obtained by the oxidation of hydrocarbons with chromic acid or of various para-di-derivatives of benzene with chromic acid mixture, such, for example, as para-aminophenol, para-phenylene diamine, para-aminophenacylamine, etc. (Bamberger, Ann., 1893, 28, p. 3121; by the action of sulphuric acid on para-substituted phenyl-hydroxyaminas (E. Bamberger), and by the action of the Grignard reagent on quinones (Bamberger). They are crystalline solids which are readily converted into para-alkylated phenols by reducing agents. They possess a weak acid and also an alcoholic character.

**QUINOLINES** (Benzoxyprazines), in organic chemistry, heterocyclic compounds containing a ring complex made up of a benzene ring and a pyrazine ring (formula I); they are isoceric with the cinnolines, phthalazines and quinazolines. They are formed by the condensing ortho-di-derivatives with 1,2-diketones (Hinsberg, Ann., 1887, 237, p. 327), the parent substance of the group (quinolxalin) resulting when glyoxal is so condensed, whilst substitution derivatives arise when a-ketoacids, a-chloroketones, a-alddehyde alcohols and a-ketone alcohols are used in place of diketones.

**QUINOXALINES** (Benzoxyprazines), in organic chemistry, heterocyclic compounds containing a ring complex made up of a benzene ring and a quinoxaline ring (formula I); they are isoceric with the cinnolines, phthalazines and quinazolines. They are formed by the condensing ortho-di-derivatives with 1,2-diketones (Hinsberg, Ann., 1887, 237, p. 327), the parent substance of the group (quinolxalin) resulting when glyoxal is so condensed, whilst substitution derivatives arise when a-ketoacids, a-chloroketones, a-alddehyde alcohols and a-ketone alcohols are used in place of diketones.

**QUINONES—QUINTAIN**

In absolute ether containing ignited sodium sulphate and then adding dry silver oxide, obtained the quinone in dark red crystalline plates which decompose between 60° and 70° C.

For naphthalene quinones see **NAPHTHALENE**; for anthracone quinone see **ANTIRHODINE**; and for phenanthrene quinone see **PHENANTHRENE**.

Quinones—The quinones are a series of compounds of the type \( R_2\)N-C=O, obtained by the oxidation of para-alkylated phenolic acids, with nitric acid, Caro's acid or bromine (Auwers, Ber., 1897-1909; E. Bamberger, ib., 1903, 36, p. 2028; Th. Zinke, ib., 1895, 28, p. 3121); by the action of sulphuric acid on para-substituted phenyl-hydroxyaminas (E. Bamberger), and by the action of the Grignard reagent on quinones (Bamberger). They are crystalline solids which are readily converted into para-alkylated phenols by reducing agents. They possess a weak acid and also an alcoholic character.

QUINTANA, MANUEL JOSÉ (1772–1837), Spanish poet and man of letters, was born at Madrid on the 11th of April 1772, and after completing his studies at Salamanca was called to the bar. In 1808 he produced a tragedy, El Duque de Viseo, founded on M. G. Lewis’s Castle Spectre; his Pelayo (1805), written on a patriotic theme, was more successful. The first volume of his Vidas de Españoles célebres (1807–33), containing lives of Spanish patriots, stirred the public imagination and secured Quintana the post of secretary to the Cortes during the French invasion. His proclamations and odes fanned the national enthusiasm into flame. But he was ill rewarded for his services, for on the return of Ferdinand VII. he was imprisoned at Pamplona from 1814 to 1820. He was finally given a small post in the civil service, became tutor to Queen Isabella, and was nominated senator. Though publicly "crowned" as the representative poet of Spain (1853), he seems to have lived in poverty. He died on the 11th of March 1857. His poems, thirty-four in number, are inspired by philanthropy and patriotism; the style is occasionally gallicized, and the thought is not profound, but his nobility of sentiment and resounding rhetoric attract every generation of Spaniards.

See an excellent monograph by E. Piñeyro, Manuel José Quintana, ensayista (Madrid, 1899).

QUINTAESSENCE, in ancient and scholastic philosophy, the name given to the fifth immaterial element, over and above the four material elements, air, water, earth and fire, which Aristotle assumed to be permeating the whole world, and called oikia: in medieval philosophy this was called quinta essentia, the fifth essence, and by many was considered material and therefore capable of extraction. The ancient Indian philosophers also contain the same idea of a fifth element; thus there were five Sanskrit elements (bhutas), earth, wind, fire, water and ether. In the history of chemistry the name was applied, by analogy, to the most concentrated extract of a substance.

QUINTILIAN [Marcus Fabius Quintilianus] (c. A.D. 35–95), Roman rhetorician, was born at Calagurris in Spain. Concerning his family and his life but few facts remain. His father taught rhetoric, with no great success, at Rome, and Quintilian must have come there at an early age to reside, and must have grown up to manhood. The years from 61 to 68 he spent in Spain, probably attached in some capacity to the retinue of the future emperor Galba, with whom he moved to the capital. For some years after the accession of Galba he was at the head of the foremost school of oratory in Rome, and may fairly be called the Isocrates of his time. He also gained some, but not a great, repute as a pleader in the courts. His greatest speech appears to have been a defence of the queen Berenice, on what charge is not known. He appears to have been wealthy for a professional man. Vespasian created for him a professorial chair of rhetoric, liberally endowed with public money, and from this time he was unquestionably, as Martial calls him, "the supreme controller of the restless youth." About the year 88 Quintilian retired from teaching and from pleading, to compose his great work on the training of the orator (Institutio Oratoria). After two years' retirement he was entrusted by Domitian with the education of two grand-nephews, whom he destined as successors to his throne. Quintilian gained the titular rank of consul, and probably died not long before the accession of Nerva (A.D. 96). A wife and two children died early.

Such is the scanty record that remains of Quintilian's uneventful life. But it is possible to determine with some accuracy his relation to the literature and culture of his time, which he powerfully influenced. His career brings home to us the vast change which in a few generations had passed over Roman taste, feeling and society. In the days of Cicero rhetorical teaching had been entirely in the hands of the Greeks. The Greek language, too, was in the main the vehicle of instruction in rhetoric. The first attempt to open a Latin rhetorical school, in 94 B.C., was crushed by authority, and not until the time of Augustus was there any professor of the art who had been born to the full privileges of a Roman citizen. The appointment of Quintilian as professor by the chief of the state marks the last stage in the emancipation of rhetorical teaching from the old Roman prejudices.

During the hundred years or more which elapsed between the death of Cicero and the birth of Quintilian education all over the Roman Empire had spread enormously, and the education of the time found its end and climax in rhetoric. Mental culture was for the most part acquired, not for its own sake, but as a discipline to develop skill in speaking, the paramount qualification for a public career. Rome, Italy and the provinces alike resounded with rhetorical excitements, which were promoted on all sides by professorships, first of Greek, later also of Latin rhetoric, endowed from municipal funds. The mock contests of the future orators roused a vast amount of popular interest. In Gaul, Spain and Africa these pursuits were carried on with even greater energy than at Rome. The seeds of the existing culture, such as it was, bore richer fruit on the fresh soil of the western provinces than in the exhausted lands of Italy and the East. While Quintilian lived, men born in Spain dominated the Latin schools and the Latin literature, and he died just too soon to see the first provincial, also of Spanish origin, ascend the imperial throne of Rome.

As an orator, a teacher, and a critic, Quintilian set himself to ensuring the current of popular taste which found its expression in what we are wont to call silver Latin. In his youth the influence of the younger Seneca was dominant. But the chief teacher of Quintilian was a man of another type, one whom he ventured to class with the old orators of Rome. This was Domitius Afer, a rhetorician of Nimes, who rose to the consulship. Quintilian, however, owed more to the dead than to the living. His great model was Cicero, of whom he speaks at all times with unbounded eulogy, and whose faults he could scarcely bear himself to mention; nor could he well tolerate to hear them mentioned by others. The reaction against the Ciceronian oratory which had begun in Cicero’s own lifetime had acquired overwhelming strength after his death. Quintilian failed to check it, as another teacher of rhetoric, equally an admirer of Cicero, had failed—the historian Livy. Seneca the elder, a clear-sighted man who could see in Cicero much to praise, and who was not blind to the faults of his own age, condemned the old style as lacking in power, while Tacitus, in his Dialogue on Orators, included Cicero among the "frozen" and "unkempt" antiquities. The great movement for the poetization of Latin prose which was begun by Sallust ran its course till it culminated in the monstrous style of Fronto. In the courts judges, juries and audiences alike demanded what was startling, quaint or epigrammatic, and the speakers practised a thousand tricks to satisfy the demand. Oratory became above all things an art whose last thought was to conceal itself. It is not surprising that Quintilian’s forensic efforts won for him no lasting reputation among his countrymen.

The Institutio Oratoria is one long protest against the tastes of the age. Starting with the maxim of Cato the Censor that the orator is "the good man who is skilled in speaking," Quintilian takes his future orator at birth and shows how this goodness of character and skill in speaking may be best produced. No detail of training in infancy, boyhood or youth is too petty for his attention. The parts of the work which relate to general education are of great interest and importance. Quintilian postulates the widest culture; there is no form of knowledge from which something may not be extracted for his purpose; and he does not confine his method in education.

He ridicules the fashion of the day, which hurried over preliminary cultivation, and allowed men to grow grey while declaiming in the schools, where nature and reality were forgotten. Yet he develops all the technicalities of rhetoric with a fulness to which we find no parallel in ancient literature. Even in this portion of the work the illustrations are so apposite and the style so dignified and yet sweet that the modern reader, whose initial interest in rhetoric is of necessity faint, is carried along with much less fatigue than is necessary to master most parts of the rhetorical writings of Aristotle and Cicero. Quintilian’s literary sympathies are extraordinarily wide.
obliged to condemn, as in the case of Seneca, he bestows generous and even extravagant praise on such merit as he can find. He can convey with equal facility the true force and spirit of the style which he combats, while he will not suffer Lucilius to lie under the aspersions of Horace. The passages in which Quintilian reviews the literature of Greece and Rome are justly celebrated. The judgments which he passes may be in many instances traditional, but, looking to all the circumstances of the time, it seems remarkable that there should then have lived at Rome a single man who could make them his own and give them expression. The form in which these judgments are rendered is admirable. The gentle justness of the senti-ments is accompanied by a curious felicity of phrase. Who can forget "the immortal swiftness of Sallust," or "the milky richness of Livy," or how "Horace soars now and then, and is full of sweetness and grace, and in his varied forms and phrases is most fortunately bold"? Ancient literary criticism perhaps touched its highest point in the hands of Quintilian.

To comprehensive sympathy and clear intellectual vision Quintilian added refined tenderness and freedom from self-assertion. Taking him all in all, we may say that his personality must have been the most attractive of his time—more winning and at the same time more lofty than that of the younger Pliny, his pupil, into whom no small portion of the master's spirit, and even some tincture of the master's literary taste, was instilled. It does not surprise us to hear that Quintilian attributed any success he won as a pleader to his command of pathos, a quality in which his great guide Cicero excelled. In spite of some extravagances of phrase, Quintilian's lament (in his sixth book) for his girl-wife and his boy of great promise is the most pathetic of all the lamentations for bereavement in which Latin literature is so rich. In his precepts about early education Quintilian continually shows his shrinking from cruelty and oppression.

Quintilian for the most part avoids passing opinions on the problems of philosophy, religion and politics. The pro-fessed philosopher he disliked almost as much as did Isocrates. He deemed that ethics formed the only valuable part of philosophy and that ethical teaching ought to be in the hands of the rhetoricians. In the divine government of the universe he seems to have had a more than ornamental faith, though he doubted the immortality of the soul. As to politics Quintilian, like others of his time, felt free to eulogize the great anti-Caesarian leaders of the dying republic, but only because the assumption was universal that the system they had championed was gone for ever. But Quintilian did not trouble himself, as Statius did, to fling stones at the emperors Caligula and Nero, who had missed their delification. He makes no remark, laudatory or otherwise, on the government of any emperor before Domitian. No character figured more largely in the rhetorical controversies of the schools than the ideal despot, but no word ever betrayed a consciousness that the actual occupant of the Palatine might exemplify the theme. Quintilian has often been reproached with his flattery of Domitian. No doubt it was fulsome. But it is confined to two or three passages, not thrust continually upon the reader, as by Statius and Martial. To refuse the charge of Domitian's expected successors would have been perilous, and equally perilous would it have been to omit from the Institutio Oratoria all mention of the emperor. And there was at the time only one dialect in which a man of letters could speak who set any value on his personal safety. There was a choice between extinction and the writing of a few sentences in the loath-some court language, which might serve as an official test of loyalty.

The Latin of Quintilian is not always free from the faults of style which he condemns in others. It also exhibits many of the usages and constructions which are characteristic of the Latin of the Decadence. But no writer of the Decadence departs less widely from the best models of the late republican period. The language is on the whole clear and simple, and varied without resort to rhetorical devices and poetical conceits. Besides the Institutio Oratoria, there have come down to us under Quintilian's name 19 longer

[ed. Lahert, 1905] and 145 shorter [ed. Ritter, 1884] Declamationes, or school exercitationes on themes like those in the [ed.] Controversiae of Seneca the elder. The longer pieces are certainly not Quintilian's. The shorter were probably published, if not by himself, at least from notes taken at his lessons. It is strange that they could ever have been suppressed, even if where they were not pronounced, to the致力 of Quintilian's school and time. The works of Quin-tilian have often been edited. Of the editiones of the whole works the chief is that by Burman (1726); of the Institutio Oratoria that by Spalding, completed by Zumt and Bonnell (1818-1853; 5th ed., Meister, 1882, the last volume containing a lexicon), and that by Halm (1868), and another by Meister (1886); Eng. trans., J. S. Watson (1856). The tenth book of the Institutio Oratoria has been separately edited by Krueger (ed. 3, 1888), Peterson (1891), Bonnell, Mayor and others. (J. R. S.)

QUINTUS SMYRNAEUS, Greek epic poet, probably flourished in the latter part of the 4th century B.C. He is sometimes called Quintus Calaber, because the only MS. of his poem was discovered at Otranto in Calabria by Cardinal Bessarion in 1450. According to his own account (xii. 310), he tried his hand at poetry in his early youth, while tending sheep at Smyrna. His epic in fourteen books, known as Τά μῦθον Ἐργατόρωμα, takes up the tale of Troy at the point where Homer's Iliad breaks off (the death of Hector), and carries it down to the capture of the city by the Greeks. The first five books, which cover the same ground as the Aethiopis of Arctinus of Miletus, describe the doleful deeds and deaths of Penthesileia the Amazon, of Memnon, son of the Morning, and of Achilles; the funeral games in honour of Achilles, the contest for the arms of Achilles and the death of Ajax. The remaining books relate the exploits of Neoptolemus, Euryppus and Delphobus, the deaths of Paris and Oenome, the capture of Troy by means of the wooden horse, the sacrifice of Polyxena at the grave of Achilles, the departure of the Greeks, and their dispersal by the storm. The poet has no originality; in conception and style his work is not inferior to that of Homer. His Iliad was often borrowed from the cyclic poems from which Virgil (with whose works he was probably acquainted) also drew, in particular the Aethiopis of Arctinus and the Little Iliad of Lesches. Edition princeps by Aldus Manutius (1504); Köchly (ed. major with elaborate prolegomena, 1850; ed. minor, 1853); Z. Zimmermann (author of other valuable articles on the poet), (1981); see O. E. Brotzen, Quin- tarque, Poëmes d'Homère, l'Iliade (1886); C. A. Sainte-Beuve, Étude sur Quin- tarque de Smyrne (1857); F. A. Paley, Quintus Smyrnaeus and the "Homer" of the tragic Poets (1879); G. W. Pachal, A Study of Quintus Smyrnaeus (Chicago, 1904).

QUIBUS (Kibpus, Qibpos), the ancient Peruvian name for a method of recording which was in use at the time of the arrival of the Spaniards. It consisted of a cord two feet in length to which were attached knots, one on the end (the quipus, quipu, quipu, a knot) hanging like a fringe. These strings were coloured, and the knots, their number and size, their distance apart, the colours, the order in which the coloured threads hung, all had a signification, e.g. white was silver, yellow gold; white meant peace, red war, &c. In this manner a rough register of important events, of births, deaths and marriages, and other statistics was kept, the quipus even constituting a rude history of the people. They were also much used for conveying orders to military chiefs in the provinces.

The idea of knotted strings to aid memory is so simple that it is common to many peoples. A Pelew islander, visiting England, knotted strings as a diary of all that struck him during his travels. In the Hawaiian Islands native carriers have knotted-string records of their rounds. The Peruvian quipus is simply the perfecting of a system of mnemonics common to the Red Indians. See also WAMPUM.

QUIRE (in earlier forms quaeer, quaer, quere, from the O. Fr. quaer, modern cahier, a copy-book, manuscript book; Lat. quaerent or set of four, from quaelus, originally the term for four sheets of paper or parchment folded so as to make eight leaves, the ordinary unit in manuscripts and early printed books; the term is now chiefly applied to a twentieth part of a ream of writing paper, twenty-four sheets. In bookbinding and publishing the expression "in quires" is used of the sheets of a book when not folded or bound. "Quire" was formerly
used of a small book contained in a single quire of paper, and so is frequently found in the title of short poems, treatises, &c. A familiar example is the Kings Quair of King James I. of Scotland. "Choir," a body of singers or the part of a church where the singers sit, was formerly spelled "quire," following the pronunciation of the word (See Choir).

**Quirinus**, the Sabine name of the god Mars, probably an adjective meaning "wielder of the spear" (Quiris, cf. Janus Quirinus). Other suggested etymologies are: (1) from the Sabine town Cures; (2) from curia, i.e. he was the god of the Roman state as represented by the thirty curies. A. B. Cook (Class. Rev. xviii., p. 368) explains Quirinus as the oak-god (querces), and Quirites as the men of the oaken spear. From early times he was worshipped at Rome on the Quirinal hill, whither, according to tradition, a body of Sabines under Titus Tatius had migrated from Cures and taken up their abode. In the religious system of Numa, Quirinus and Mars were both recognized as divine beings, distinct but of similar attributes and functions; thus, like Mars, Quirinus was at once a god of war and a nature god, the protector of fields and flocks. Subsequently, at the end of the republic, Quirinus became identified with the greatest of the Roman deities. On the latter the greater flamens was attached to the service of Quirinus, a second college of Sali founded in his honour, and a festival "Quirinalia" celebrated on the 17th of February, the day of the supposed translation of Romulus to heaven. Old Roman formulae of prayer mention a Hora Quirini, his female cult associate, afterwards identified with Hersilia, the wife of Romulus.

The name was also borne by the following saints: (1) a Roman tribune who suffered martyrdom under Hadrian; (2) a bishop of Siscia in Pannonia; (3) the patron of the Tegernsee in Bavaria, beheaded in Rome in 266 and invoked by those suffering from gout. The petroleum (Quirinus-oil) found in the neighbourhood of the lake takes its name from this nymph.

**Quirites** (literally "spear-men"; see **Quirinus**), the earliest name of the burgesses of Rome. Combined in the phrase "populus Romanus Quirites (or Quirillum)" it denoted the individual citizen as contrasted with the community. Hence **Quirimum** in Roman law is full Roman citizenship. Subsequently the term lost the military associations so original to the conception of the people as a body of warriors, and was applied (sometimes in a depreciatory sense, cf. Tac. Ann. i. 42) to the Romans in domestic affairs, Romani being reserved for foreign affairs. (For the distinction between Quiritary and praetorian ownership, see **Roman Law**.)

**Quito**, the capital of the republic of Ecuador, the seat of an archbishopric covering the same territory, and the capital of the province of Pichincha, in lat. °14'S., long. 79° 45' W., about 114 m. from the Pacific coast and 165 m. in a direct line N. E. of Guayaquil, with which it is connected by a railway completed in 1908. Pop. (1906) 30,840, of whom 13,65 were foreigners, mostly Colombians. It occupies a small basin of the great central plateau formed by the volcano Pichincha on the S., the Puey river ridge on the E., and ridges N. and S. forming the eastern edge of the Pichincha. The ground upon which the city is built is uneven and is traveled from W. to E. by two deep ravines (quebradas), one of which is arched over in great part to preserve the alignment of the streets, the drainage of which escapes through a cleft in the ridge northward to the plain of Tumbaco. The city is in great part laid out in rectangular squares, the streets running nearly with the cardinal points of the compass. The houses of Quito are chiefly of the old Spanish or Moorish style. The building material in general use is sun-dried bricks, which in the better houses is covered with plaster or stucco. The public buildings are of the heavy Spanish type. Facing the principal square (Plaza Mayor), and occupying the whole S. side, is the cathedral; on the W. side is the government palace; on the N. the archbishop's palace; and on the E. the municipal hall. The elevation of this plaza is 9,343 ft. above sea-level. The finest building in the city is the Jesuits' church, whose façade is covered with elaborate carving. Among public institutions are the university, which occupies part of the old Jesuit college, an astronomical observatory, and eleven large monastic institutions, six of which are for nuns. One of the convents, that of San Francisco, covers a whole block, and ranks among the largest institutions of its kind in the world. A part of it is in ruins, and another part has been for some time used as military barracks by the government. The university has faculties of theology, law and medicine, and has 200 to 250 students, but it is antiquated in character and poorly supported. The eminent botanist and chemist, Dr. William Jameson (1796–1872), was a member of its faculty for many years. The city has no large commercial houses, and only an insignificant export trade, chiefly hides and forest products from the wooded mountain slopes near by. Religious paintings of a medieval type are produced in large numbers and exported. The native manufactures include tanned leather, saddles, shoes, ponchos, woollen and cotton cloth, fibre sandals and sacking, blankets, coarse matting and coarse woollen carpets. Superior hand-made carpets are also made, and the Quito artisans show much skill in wood carvings and in gold and silver works; the women excel in fine needlework and lace-making.

Quito derives its name from the Quitus, who inhabited the locality a long time before the Spanish conquest. In 1533 Sebastian Benalcazar took peaceable possession of the native town (which had been successively a capital of the Sefiris and Incas), and in 1541 it was elevated to the rank of a Spanish city. Its full title was San Francisco del Quito, and it was capital of the province or presidency of Quito down to the end of Spanish colonial rule. It has suffered repeatedly from earthquakes, the greatest damage occurring from those of 1797 and 1859.

**Quiver**, a case for holding arrows. The word is taken from O. Fr., where it appears in such forms as quivre, cuivre or cuivre. This is apparently cognate with the O. E. cower, Ger. Kocker, quiver or case. The ultimate origin is obscure, and the medieval Latin and Greek words caurum and toxodov are stated to be from the German. The word meaning "to shake" or "tremble" must be distinguished; this is connected with the word quiver, "quake," the *New English Dictionary* takes these words to be onomatopoeic in origin.

**Quoins** (an old variant spelling of "coin," from Lat. cuneus, a wedge), in architecture, the term for the external angle of a building, generally applied to the ashlar masonry employed to stop the rubble masonry or brickwork of the wall at the angles, as also of buttresses, doorways or projecting features. In Saxton work the quoins were built with large stones laid horizontally and vertically in alternate courses, technically known as "long and short" work. Sometimes, to give greater importance to the angles of towers, the quoin stones are rusticated, and this treatment is found extensively employed in ancient German towns. At Eastbury Manor House in Essex, built in brick, the quoins at the angles of the walls, doorways and windows were plastered in imitation of stonework.

**Quoits** (O. Fr. coiler, quoler, to incite), a pastime resembling the ancient discus-throwing which formed one of the five games of the Greek pentathlon (see Discus), the two main differences between the ancient and modern sports being that the quoit is ring-shaped (one surmounting the other) (see Frisbee—flat) and is lighter than the discus, and its throwing is a test rather of accuracy than strength. Few traces of a game resembling quoits can be found on the continent of Europe, and its origin may be sought for on the borderland of Scotland and England. There are references to it in the Midlands dating from the beginning of the 15th century, and it was one of the games prohibited in the reigns of Edward III. and Richard II. in favour of archery. Ascham, in his *Toxophilus* (1545), says that "quoting be too vile for scholars," and in old times it was chiefly played by the working classes, who often used horse-shoes for want of quoits, a custom still prevailing in country districts. According to the modern rules, slightly modified from the code drawn up in 1869, two iron or steel pins 18 yds. apart are driven into the ground, leaving 1 in. exposed. Each is situated in the centre of an "end," a circle of stiff clay 3 ft.
QUORUM—QUO WARRANTO

in diameter. The quotas, made of iron, may be of any weight, but are usually about 9 lb each. They must not exceed 8\frac{1}{2} in. in diameter, or be less than 3\frac{1}{2} in. in the bore, or more than 2\frac{1}{2} in. in the web. When delivering his quoit a player must stand within 4 ft. 6 in. of the centre of the end and at its side. Matches are played between teams or individuals, the object of the game being to throw the quoit as near to the pin as possible, a “ringer,” i.e., a quoit actually surrounding the pin, counting two, and a quoit nearer to the pin than any of the adversary’s, counting one. A match may be for any number of points, the team or player scoring that number first being the winner. In championship matches all quotas farther than 18 in. from the end, are foul and removed. All measurements are made from the middle of the pin to the nearest edge of the quoit. If one or more quotas are lapped, the one most accessible is first measured and withdrawn. All quotas on their backs are a foul. The general principle of curling, to drive the opponents’ quotas away from the pin and place one’s own near or on it, is followed.

Scotland, Lancashire and the Midlands are the principal centres of quoitling in Great Britain. In Scotland the game is patronized by the Curling Clubs, and this is also the case in the United States and Canada. Billy Hodson was champion of Great Britain in the middle of the 19th century, and his trip to America in the early 1860s was of historical interest, as it resulted in two contests for the championship of the world with James McLarten of Newark, N. J., a native of Scotland, who was champion of America. One hard-fought match was won by each, the deciding one remaining unplayed. The championship of America is rewarded by the “Ball Medal,” presented by the Grand National Curling Club of America.

QUORUM (Lat. for “of whom”), in its general sense, a term denoting the number of members of any body of persons whose presence is requisite in order that business may be validly transacted by the body or its acts be legal. The term is derived from the wording of the commission appointing justices of the peace which appoints them all, jointly and severally to keep the peace in the county named. It also runs—“We have also assigned you, and every two or more of you (of whom [quoit]), any one of you the aforesaid A, B, C, D, &c., we will shall be one) our justices to inquire the truth more fully,” whence the justices so-named were usually called justices of the quoit. The term was afterwards applied to all justices, and subsequently by transference, to the number of members of a body necessary for the transaction of its business. No general rule can be laid down as to the number of members of which a quoitum should consist; its size is usually prescribed by definite enactment or provision; it is entirely a matter for self-constituted bodies as to what their quoitum shall be, and it usually depends on the size of the body. In bodies which owe their existence to an act of the legislature, the necessary quoitum is usually fixed by statute. In England, in the House of Lords, three form a quoitum, though on a division there must be thirty members present. In the House of Commons, forty members, including the Speaker, form a quoitum. The quoitum of a standing committee of the House of Lords is seven, and of the House of Commons, twenty.

QUOTA, a proportional share or part that is due from or to any person or body of persons, in Med. Lat. quota, sc. pars, from quotus, an adjective formed from quot, how many. The word first appears in connexion with the levying of men, money or supplies for military and naval purposes from districts, towns or seaports, and thus is equivalent to “contingent” (Lat. contingere, to happen to, fall to one’s lot or share, cum, with, and tangere, to touch), used since the 18th century specifically of a contribution of men or ships according to a scale fixed between the contracting parties.

QUOTATION, a passage repeated from the writings or speech of another. The verb “to quote” comes from Med. Lat. quotare (from quot, how many), to refer to by numbers, i.e. of page, chapter, &c., also to separate into chapters, verses, &c. The term is also specifically applied to the statement of the current prices of goods and commodities, and of stocks and shares (see STOCK EXCHANGE).

Useful lists of familiar quotations may be found in the following:—H. T. Riley, Dictionary of Latin and Greek Quotations, ed. Bohn; P. H. Dalbiac, Dictionary of English Quotations (1906) in the various series, T. B. Harbottle, Classical Quotations (1807), and T. B. Harbottle and P. H. Dalbiac, French and Italian Quotations (1901); Robinson Smith, English Quotations (n.d.); H. P. Jones, A New Dictionary of Foreign Phrases and Classical Quotations; J. K. Hoyt and A. L. Ward, The Cyclopaedia of Practical Quotations, English and Latin (1892); Cassell’s Book of Quotations (1901); J. Bartlett, Familiar Quotations...in Ancient and Modern Literature (1902); in Notes and Queries, the indices to the various series contain, grouped under the heading “Quotation,” a large number of out-of-the-way quotations.
